Most insects of these tribes prefer stagnant waters, others those of a purer nature, and we have instances of certain insects which inhabit, with perfect convenience, springs of a warm and mineral nature. At the baths of Abano, in the Venetian states, is a spring of this description, impregnated with sulphur, in which small water beetles are seen swimming about, and which die on being taken out and plunged into cold water.

## ENTOMOLOGY.

Many insects that live under the surface of the earth in the perfect state crawl out occasionally, as the mole cricket, and some of the aptera, as the julus and scolopendra; these are generally found in the earth under stones, or beneath rotten wood in damp situations. Some insects remain underground part of their life, but quit that situation after their change, as in the coleoptera. A vast number of others live in animal substances of every kind. The habitation of some, as the myrmecoleonformicarius, is curiously constructed in the sands.

There is a species of spider found in Jamaica (*aranea venatoria*) which burrows in the earth like a rabbit; it is of a size very far surpassing the largest of the European spiders, and is not uncommon there. This creature forms a hole twelve or fifteen inches deep, of a cylindrical shape, rather more than an inch in diameter, and which it lines with a thick coat to prevent the earth from tumbling in. The aperture is closed with a kind of lid or door attached by a single hinge, and which open outwardly, falling down and shutting the aperture by its own gravity. Into this the spider retires with its prey, and devours it in safety, as few insects can penetrate into its cell. These nests or cases form a complete habitation, should the sands in which they are constructed give way.

Insects of the lepidopterous order are very rarely carnivorous; there are instances of this, but these are uncommon. Their food and that of many other insects are of the vegetable kind, and their habitations are trees and plants. The oak and the willow among trees, and numbers of different plants among herbage, are the natural habitation of insects in great abundance. Some live in the roots, others in the wood; in the leaves, and in galls formed therein; in flowers; in fruit; and in grain. Some caterpillars form a kind of hammock, in which they eat and go through their various changes; while others construct a tent, under which they live till they have consumed the surrounding herbs, when they leave their abodes and pitch their tents in another spot, where they can find abundance.

Many insects associate together all their lives, others only for a certain period. Those who live together proceed from the same moth who deposited the eggs near each other, or laid them in a heap, and thus formed a kind of nest. These are generally hatched about the same time, and live together, forming a kind of republic. These societies include two, three, or four hundred individuals, and usually live inclosed in a large web, like the lackey moth, (*phal. neustria*) and the ermine moth. Of these social caterpillars there are some kinds which never quit the society to which they belong, but pass into the pupa form in the same nest. One of the most remarkable of these caterpillar communities is that of the bombyx processionea. These live on the oak separate till they arrive at a certain age, when they associate together, and do not quit their society till they acquire their perfect form. As the number of the caterpillars thus assembled is considerable, the nest is also very large. They remain in their habitation till sun set. When they go out one of the body precedes the rest as a chief, whom they regularly follow. When the leader stops the rest do the same, and wait till it goes on again before they recommence their march. The first file generally consists of a single caterpillar, which series is succeeded by a double file, these by three in a row, which are then followed by files of five, and so on. They keep close to each other, not leaving any interval either between the ranks or between those in each rank, all following their captain in compact order, whether in a straight or irregular course. After they have taken their repast they return to the nest

in the same order as they set out. This conduct is regularly pursued till they are full grown, when each spins a cone for itself in the nest. It has been remarked, that though these caterpillars proceed often very far from the nest, it is by no means difficult for them to get back again, because they spin a thread in their route. The first leads the way, the second follows spinning, the third spins after the second, and soon forming thus a path of threads.

Upon the same tree, shrub, or plant, we often find numbers of caterpillars which have no affinity to each other, and of which the actions of one have no influence over the manners of the other; they may in this respect be considered solitary. There are others who seem still more independent of each other even than these, because they shun all intercourse, constructing lodgments formed of leaves tied together with considerable ingenuity, in which they live as in an hermitage. The operation by which these caterpillars tie the leaves together is far surpassed by another kind, who fold and bend one part of the leaf till it meets the other. These are again excelled by those who roll the leaves which they inhabit. For this purpose the caterpillar makes choice of part of a leaf which it finds in some degree bent; here its work commences, the caterpillar moving the head with great velocity in a curved line, or rather vibrating it like a pendulum, the middle of the body being the centre on which it moves. At each motion of the head a thread is spun and fixed at that part to which the head seems to be applied. The threads are extended from the bent to the flat part of the leaf, and the curvature which is to be given to it. There is another species of which it is observed, that at each new thread it spun, the edges of the leaf insensibly approached to each other, and were bent more and more, in proportion as the caterpillar spun new threads; when the last thread was spun, that which preceded it was loose and floating in the air. To effect this the caterpillar, after it has fixed a thread to the two edges of the leaf, and before it spins another, draws it towards itself by the hooks of its feet, and by this means bends the leaf; it then spins another leaf to maintain the leaf in this position, which it again pulls towards itself, and repeats the operation till it has bent the leaf in its whole direction. It now begins again placing the threads further back, upon the bent part of the leaf, and by proceeding in this manner it is rolled up; when it has finished this business it strengthens the work by fastening the ends of the leaf together. The habitations thus formed are open at both ends, and within which the insect feeds in safety. At the approach towards the pupa state, the caterpillar lines the rolled leaf with silk, that the rougher parts may not injure it.

A great number of the smaller larvæ require an artificial covering to protect them. Some inhabit the interior part of leaves in which they form large oval or circular spaces; others form a kind of gallery within, which in some is straight, in others crooked. Many of the tineæ are found lodged in cylindrical tubes or cases, which they form of different substances closely woven with fine silken threads. The small caterpillar found in neglected woollens and other similar articles is of this kind, living in a cylindrical case, and producing a small moth.

The phryganea larvæ construct cases somewhat similar in form, and which are also open at both ends; in these the larvæ reside, the outside is formed of different substances, such as bits of reed, stone, gravel, and small shells, which they arrange and manage with singular dexterity. When they walk they only advance a few of the anterior rings of the body, training the case after them. When they are

about

about to assume the pupa form they close up the ends with silken threads.

But the habitations of these insects, though constructed with ingenuity, are in no manner comparable with the architectural fabrications of many other insects, as those of the wasp, the bee, the common ant- (*formica*), the white ant (*termes*), &c. The structure of the nests constructed by the common wasp, and the common honey bee, cannot be unknown to any reader. Among the habitations of the solitary, or those called the wild bees, there are many which deserve remark. Some of the bee tribe penetrate into the earth, where they form small contiguous cavities, in each of which they deposit an egg, with a sufficient quantity of provisions for the sustenance of the larva. There is one kind whose nest consists of several cells artfully let into each other, but not covered with a common inclosure; each cell consists of two or three membranes, inexpressibly fine, and placed over each other. The cavity in which the nest is placed is smeared over with a layer of matter, like that of which the cells are formed, and apparently similar to that viscous humour which snails spread in their passage from one place to another. An egg is deposited at the bottom of each cell, where, after it is hatched, the grub finds itself in the midst of a plentiful stock of provision, for in each cell there is placed a quantity of paste, or a kind of wax, which is to serve as food for the worm, and as support to the wall of the cell.

Another species that forms its nest under ground makes a perpendicular hole in the earth about three inches deep and cylindrical, till it comes within three-fourths of an inch of the bottom, when it begins to open wider. The suitable proportions being given, the bee proceeds to line with tapestry not only the whole of the inside, but also the entrance; the substance with which it is lined is of a crimson colour, and appears as very beautiful. This lining is formed of fragments of the flowers of the poppy, which the bee cuts out curiously, and then seizing them with her legs conveys them to her nest. If these pieces are rumpled, she presses them smooth, and then affixes to the walls of her cell; or if the piece she has cut and transported is found too large, she clips off the superfluous parts, and conveys the shreds out of the apartment. After the bee has lined the cell, she fills it nearly half an inch deep with a kind of paste, proper to nourish the larva when hatched from the egg. When the bee has amassed a sufficient quantity of paste, she folds the tapestry over the paste and the egg, which is by this means inclosed as it were in a bag of paste; and the bee then fills up with earth the empty space that is above the bag. Another of the bee tribe is said to construct its nest in the same way, with this difference only, that the lining is of the corolla of the rose.

The carpenter bee (*apis centuncularis*) constructs her nest in pieces of wood, whence the name; in this she perforates long cylindrical hollows, which she divides into stages, and deposits her eggs, each inclosed in a curious cylindrical case formed of leaves, not quite an inch in length, and less than half an inch in diameter, and these are disposed endwise one above another to the amount of ten, twenty, or more, the cylindrical perforation in the wood being two or three feet long, or sometimes more. They bore the wood most commonly in the longitudinal direction of its ligneous fibres, but this is not always the case. There are several species of this order in appearance much like each other. The leaves which form the lining of the cases in one species is that of the rose.

The former are called the carpenter bees on account of

the holes which they bore in the wood; there is another which bears the name of mason bee, from the peculiar structure of the nest. Their manner of building is this: the bees collect with their jaws small parcels of earth and sand, which they glue together with a strong cement, which is furnished from the proboscis; and of this they form a simple but commodious habitation, which is generally placed along walls that are exposed to the south. Each nest resembles a lump of rude earth of about six or seven inches diameter, thrown against the wall; the labour of constructing an edifice of such magnitude must be considerable, as the bee can only carry a few grains at a time. The exterior form is rude and irregular, but the art exhibited within more than compensates for the ruggedness of the external appearance. The interior is divided into twelve or fifteen cells, separated from each other by a thick wall; in each of these an egg is deposited by the parent bee. The cells are constructed progressively, for when one is finished she places an egg in it, with a sufficient quantity of honey to nourish the larva; she then builds another, and so proceeds till all her eggs are deposited. When the young are hatched the strength of their jaws enable them to penetrate through their cells with perfect ease.

There is a species of spheg called the ichneumon wasp, whose manner of constructing the nest is still different from either of those before mentioned. This little creature generally begins its work in May, and continues its labours through the greater part of June. The object of her labour seems at first to be the digging of a hole a few inches deep in the ground, in the construction of which she forms however a hollow tube above ground, the base of which is the opening of the hole, and which it raises as high above ground as the hole is deep below; it is formed with great care, resembling a coarse kind of sillagree work, consisting of the sand drawn from the hole. The sand out of which she excavates her cell is nearly as hard as a common stone. This it readily softens with a penetrating liquor, with which she is well provided; a drop or two of it is imbibed immediately by the sand on which it falls, which is instantly rendered so soft, that she can separate and knead it with her jaws and fore feet, forming it into a small ball, which she places on the edge of the hole as the foundation stone of the pillar she is about to erect; the whole of it is formed of such balls, ranged circularly, and then placed one above the other. She leaves her work at intervals, probably in order to renew her stock of that liquor which is so necessary for her operations; these intervals are of short duration; she soon returns to her work, and labours with so much activity and ardour, that in a few hours she will dig a hole two or three inches deep, and raise a hollow pillar two inches high. After the column has been raised to a certain height perpendicularly from the hole, it begins to curve a little, which curvature increases till it is finished, though the cylindrical form is preserved. She constructs several of these holes, all of the same form and for the same purpose. It is evident the hole was dug in the ground to receive the egg, but the purpose of the tube of sand is not very apparent. By attending to the labours of the wasp, one end, however, may be discovered; it will be found to serve the purpose of a scaffold, and that the balls are as useful to the wasp as materials to the builder, and are therefore placed as much within her reach as possible. She uses it to stop and fill up the hole after she has deposited an egg in the cell, so that the pillar is then destroyed, and not the least remains left in the nest. The parent insect generally leaves ten or twelve worms as provisions for the young larva.

In all these fabrications there is a degree of ingenuity in design, and exactness of execution, which, independently of the labour required in their construction, excites our admiration. The talent, if it may be so expressed, of the insect race, is more obviously displayed in the formation of the dwellings than in most other particulars of their history. It is a pleasing subject of inquiry, and extremely worthy of attention, but for an elementary discourse we have, perhaps, already pursued these observations to a due extent, and shall therefore conclude with a concise account of one other, which, from its stupendous dimensions, the order, regularity, and beauty of its architectural design, and inimitable convenience to the purposes for which it is intended, cannot fail to excite the astonishment of every observer; it may be anticipated that the allusion is to the buildings of the termites. These diminutive insects, known more generally by the name of the white ants, though, technically speaking, they are entirely of a distinct genus, are natives of the East Indies, Africa, and the southern parts of America. They live in societies, each of which is composed of some thousand individuals, all of whom are accommodated in the same habitation. Their structures are of a pyramidal form, rising to the height of ten or twelve feet, and covering no inconsiderable extent of ground at the base. They usually build in the plains several contiguous to each other, and from their size and form may sometimes be mistaken at a distance for the huts of the natives.

These nests are so common all over the island of Bannanas, and the adjacent continent of Africa, that it is scarcely possible to stand on an open place where one of these buildings is not to be seen. The domes are so strong that they will easily bear the weight of three or four men standing on them at once, and shelter the interior from every attack of the weather. The interior is divided with the utmost regularity into an immense number of apartments, arched chambers, magazines, and avenues leading to them; and the centre, on a level with the ground, contains the royal apartment, in which the queen resides, surrounded by the nursery, &c. The white ant is the *termes fatale*: there are two, if not more, species besides, namely, *destructor* and *arda*, both inhabitants of Africa, which build nests of a similar form, but of much smaller size. See the article *TERMES*.

*Food of Insects.*

Insects feed on all kinds of vegetable and animal substances. There is scarcely any production of these two kingdoms which does not serve for food to some kinds of insects. They may therefore be considered under two heads; those which live on vegetables alone, and those supported chiefly on animal food. The organs of the mouth point out the very wide distinction nature intended in this respect, some being adapted to the purposes of mastication, others to that of suction only; some, like ruminating animals, have two stomachs, others only one; the alimentary canal in some is short, in others long, and upon the whole, their internal conformation, as well as external form, presents the most striking differences, each being in a peculiar manner adapted to the nature of the food upon which the animal subsists.

There is yet another circumstance well worthy of remark; in all those insects which undergo material change, the transformation of their external figure is accompanied with an entire revolution in their internal structure and economy; the larvæ destined to feed on vegetables, or the grub on carrion, after effecting their transformation, present no longer the same appearance within; parts adapted to their former mode of life, and inapplicable to their present one, totally

disappear, and other organs, either before not existent, or which remained concealed, are now developed. The stomach of the butterfly, when in the larva state, is adapted to the reception and digestion of its vegetable food, as its organs of mastication are to its previous preparation; but this stomach and this mouth both disappear in the butterfly, and other organs make their appearance; its mode of life is totally changed; it derives its sustenance from the nectar of flowers, and its whole conformation is adapted to its new mode of life. These arguments are not inferred from a few solitary instances; they are exemplified in numberless examples: nothing is more common than to find the larvæ subsisting on food altogether different from that which supports the same insect in the winged state.

Among those numerous tribes which feed on vegetables, some sink into the earth, where they feed on the roots of grass, and do considerable injury to gardens. The food of others is dry and hard; they pierce the wood, reduce it to powder, and then feed on it: in this manner many of the *cerambyx* tribe and other *coleoptera* feed in the larva state. Some attack the leaves, eating the whole substance, except the principal nerves; while others feed only on the parenchymous parts which are contained between its superficial membranes, forming paths and galleries within. These insects are not always content with the leaf; some eat the flowers, and even this food is too gross for many; the bee, the butterfly, the musca, and a host of others, feed only on the nectareous juices, or the farina which they collect from flowers, or the delicious fluids of fruits. Corn and other grain are not free from them; they divide the produce with us, or often deprive us of large quantities. They insinuate their larvæ into the most tender parts, and each oftentimes destroys more than would be sufficient to feed fifty of them. We frequently find the larvæ of some insects in pears, plumbs, peaches, and other fruit. There, indeed, appears scarcely any part of a plant which does not serve as food to different insects; each has its appropriate food, and though the parent animal does not, perhaps, subsist on the same vegetable, yet she instinctively deposits her eggs on that particular shrub or plant which will be food for her young: Some more voracious than the rest feed upon all with equal avidity; the migratory locust, *gryllus migratorius*, is a striking example of this. The ravages of this insect have been at particular times so extensive as to lay waste the vegetation of whole districts, of even kingdoms; an instance is mentioned in the *Amœnitates Academicæ*, in which they overran all Sweden, and devoured all the plants, inasmuch that cattle perished with hunger, and men were forced to abandon their country, and fly to the neighbouring regions. Similar results have arisen from the ravages of locusts in various parts of the world at various periods, as appears from the most credible historians. The sacred writings are not silent on this subject. In the year 593 of the Christian era these animals appeared in such vast numbers, as to cause a famine in many countries. Syria and Mesopotamia were over-run by them in 677. In 852 immense swarms took their flight from the eastern regions into the west, and destroyed all vegetables, not even sparing the bark of trees, and the thatch of the houses, after devouring the crops of corn, grass, &c. Their daily marches were observed to be about twenty miles each, and it is said their progress was directed with so much order, that there were regular leaders among them, who flew first and settled on the spot which was to be visited at the same hour the next day by the whole legion; their marches were always undertaken at sun-rise. In 1541 incredible hosts afflicted Poland, Wallachia, and all the adjoining territories, darkening the sun with their num-

bers, and ravaging all the fruits of the earth. The years 1747 and 1748 afforded a memorable instance of the ravages of these animals in Germany and other parts of Europe, as far north as England. In the eastern parts of the world such flights of locusts appear more frequently than in Europe, and it is often found necessary for the governors of particular provinces to command a certain number of the military to take the field against armies of locusts with a train of artillery.

The far greater number of insects feed, however, more discriminately; some are confined to one particular plant, and others only to two or three kinds; and neither in many cases will eat any other food; they often perish in the midst of abundant vegetation, because they cannot procure that kind which is their natural food. The quantity of food which a caterpillar will devour is astonishing; that which feeds upon the cabbage (*papilio brassicæ*) destroys in twenty-four hours more than twice its weight. If larger animals required a proportionable quantity of food, the earth would not be able to nourish its inhabitants. It should, however, be remembered, that it is only during one period of their lives that they are so voracious, or subsist on such food; after they quit the larva form they are nourished in a different manner.

A vast number of insects reject vegetables in the larva state, and live only on animal food; some seeking that which is beginning to putrefy, while others delight in that which is entirely putrid, or on the dung of animals. Some attack and feed on man himself, while others are nourished by his victuals, clothes, furniture, and habitation; and again others prey on his cattle. No animal whatever is exempt from these depredators. Some subsist on the blood and humours of quadrupeds, others of birds, and a great proportion of them prey on insects of other kinds, or often attack their own, and thus perpetuate an endless war among each other.

Every larger animal has its appropriate lice, which feed on and infest it: these in size or voracity bear no regular proportion to the animal they subsist upon. Those of man are diminutive in the extreme, compared with those which torment some animals. The hippoboscæ and the tick, though not in technical terms the lice of the animals they infest, have the same habits, and draw nourishment from the body in the same manner; and these, in comparative bulk with the victims of their depredation, are an hundred, nay even, in some instances, a thousand times larger than these uncleanly vermin in man. Some are not content with the blood and juices which they suck from animals; they seek their food in the flesh, and that while full of life and health. The oestri, or gad-flies, are familiar examples of this, the larva feeds upon the flesh beneath the skin in cattle. The parent lodges its eggs in the flesh by making a number of little wounds, in each of which it deposits eggs, so that every wound becomes a nest, and the eggs are hatched by the heat of the animal. Here the larva finds abundance of food, and is at the same time protected from the changes of the weather, and they undergo their transformations in security. The parts they inhabit are often discovered by a lump or tumour which they occasion; this suppurates, and is filled with matter, in which the head of the larva is always found plunged. When the time of change arrives the larva drops out, and seeks a convenient place in the ground, where it passes to the pupa state. The ravages of the larva hatched from the ichneumon eggs, in the body of the caterpillar, are still more destructive, as they entirely destroy the vitals of their victims. The number of insects which are of a carnivorous disposition is very great; and it

is among these we find the traces of the greatest art and cunning, as well for attack as defence. Every one is acquainted with the dextrous arts of the spider, to seize his prey, the curious nest he spins, and the central position he assumes in order to watch more effectually the least motion communicated to its tender threads when the incautious insects settle upon it. D.

ENTONNER, *Fr.* in *Roman Catholic Churches*, is announcing to the choir the tone or sound with the organ, or the voice of the officiating priest, with which a chant, hymn, psalm, or anthem is to begin. In our cathedrals this is done for the responses by a canon, vicar choral, or by a single note on the organ.

ENTORSIS; in the *Manege*. See PASTERNA.

ENTOYER, or ENTOIRE, in *Heraldry*, is used to express a bordure, charged entirely with things without life. See BORDURE.

ENTRACQUE, in *Geography*, a town of Italy, in the principality of Piedmont, on the Gesso; 5 miles S.S.E. of Demont.

ENTRACTE, *Fr.* the space of time which elapses between the end of one act of a drama and the beginning of another; and during which the representation is suspended, while the action is supposed to be advancing elsewhere. The orchestra fills up this space by performing a symphony, which supplies the place of what used, in England, to be called an *ad-tune*.

It does not appear that the Greeks ever divided their dramas into acts; consequently, they had no act-tunes. The representation was never suspended on their stage empty from the beginning of the piece to the end.

The Romans, less interested in these exhibitions than the Greeks, were the first who divided their pieces into several distinct parts, the intervals of which afforded a relaxation to the attention of the spectators; and this custom has been continued elsewhere ever since.

But as the entract was intended to suspend the attention, and give some repose to the mind of the audience, the stage should have remained vacant. But the interludes with which the vacuity was formerly filled furnished an interruption in a very bad taste, which infallibly injures the piece in breaking the thread of the action.

However, Moliere himself did not see so simple and obvious a truth; the spaces between the acts of his last pieces were filled with interludes.

The French, whose public spectacles have more reason than enthusiasm in them, and who dread being long kept in silence, have since reduced their interacts to their due simplicity, and it is to be wished for the perfection of the drama that they were imitated, in that particular, every where else.

The Italians, whom an exquisite sensibility often guides better than reason, have proscribed the dance of the dramatic action (see OPERA); but by an inconsistency arising from the too long duration which they allow to their representations, they fill their interacts with ballets, which banish them from the piece, in representation, and if they avoid the absurdity of a double imitation, they give into an equal absurdity by a transposition of scene, and by harassing the spectator from object to object, they make him forget the principal action, lose the interest, and, in order to give pleasure to his eyes, rob him of those of the heart.

They began, however, to feel (in 1768) the defect of this monstrous assemblage; and after having already almost driven intermezzi from their stage, they will doubtless ere long, get rid of the dance, reserving it only as a brilliant and detached spectacle at the end of the grand piece.

But though the stage remains vacant during the intera<sup>c</sup>t, it is not to be understood that the music ought to be silenced; for at the opera, where it constitutes the principal existence of every thing, the sense of hearing ought to be so connected with that of sight, that as long as the stage is seen the harmony should be heard, which is supposed inseparable from it; so that its concurrence may not appear afterwards foreign or new, but united with the melody of the vocal performers. Chiefly from Rousseau.

The difficulty which presents itself on this subject, is to suggest what the composer ought to dictate to the orchestra when nothing is doing or transacting on the stage: for if the symphony, as well as all dramatic music, is only a continued imitation, what is it to say when nobody speaks? What ought it to do when there is no action? "I answer to that (says Rousseau) that though the stage is vacant the heart of the spectator is not; there ought to remain a strong impression of what has been seen and heard. It is for the orchestra to cherish and sustain this impression during the intera<sup>c</sup>t, that the spectator at the beginning of the ensuing act may not find himself as cold as at the beginning of the piece, but that the interest may be as much linked in his mind as the events are in the action represented.

By this means the musician will always have an object of imitation, either in the situation of the personages, or in that of the spectators. These should hear nothing from the orchestra but expressions of what they have felt, identified with what they hear; and their situation will be so much the more delicious, as there shall be a more perfect accord between that which strikes their senses and which touches the heart.

An able musician will draw from the orchestra another advantage, which will contribute to give the representation all the effect possible, in conducting the spectator, by degrees, to the state of mind the most favourable to the effect of the scenes which are going to be represented in the following act.

The intera<sup>c</sup>t has no fixed duration; but it is supposed to be more or less considerable, in proportion to the time necessary for that part of the action, which is passed behind the scenes. However, that duration should have its bounds of supposition, relative to the hypothetic duration of the whole action; and the real bounds relative to the duration of the whole representation.

This is not the place to examine whether the rule of 24 hours is well founded, and if it ought never to be violated. But if we would give to the supposed duration of an intera<sup>c</sup>t bounds regulated by the nature of things, I see no other rule than that of the time during which no sensible and regular change happens in nature, which cannot be made apparently transacting on the stage during the intera<sup>c</sup>t. Now this time being 12 hours, which compose a day or a night, if that is exceeded, there is no longer any possibility of illusion during the supposed length of the act."

This is reviving the old contention concerning the unities, which have never been received as a law in this country. And as to act-tunes analogous to the business of the drama, it is an idea which was executed by Purcell in many of the plays of Dryden and Congreve; and Arne, when composer in salary at Drury-lane theatre, composed very pleasing and appropriate act-tunes to many of the stock plays, which never were printed, but preserved in MS. in the archives of the old theatre; but we suppose that the strains of Orpheus or Amphion might be as easily recovered now as these compositions.

ENTRAIGUES, in *Geography*, a small town of France, in the department of the Aveyron, chief place of a canton,

in the district of Espalion, with a population of 1748 individuals. It is situated near the place where the river Truyere falls into the Lot, 18 miles S. of Aurillac. Its canton contains 6 communes, and 6691 inhabitants, on a territorial extent of 147½ kilometres.—Also, a small town of France, in the department of the Isère, chief place of a canton, in the district of Grenoble, with a population of 521 individuals. The canton contains 10 communes and 4988 inhabitants, on a territorial extent of 355 kilometres.—Also, a small town of France, in the department of Vaucluse, 6 miles N.E. of Avignon.

ENTRAILS, the intestines or guts of an animal. See *INTESTINES*.

Menage derives the word from the barbarous Latin, *interalia*, formed of the Greek, *εντερον*, *intestine*.

ENTRAILS is also used, in a more extensive sense, for the viscera, or all the parts contained in the cavities of the bodies of animals. See *VISCERA*.

The aruspina of the ancients was employed in considering the entrails of victims; as the heart, lungs, liver, &c. See *ARUSPICES*, &c.

ENTRANCE, in *Sea Language*, is a name often given to the foremost part of a ship under the surface of the sea.

ENTRANCE of hounds, a phrase used by our *Sportsmen*, to express the instruction of these creatures in the art of hunting. They are said to be entered when they are thoroughly taught this.

The time of entering of hounds is when they are about twelve months old; when they are first brought up from their walks, they should be kept separate from the pack: they are then to be taught to take the water and swim; they are to be laid abroad in the heat of the day, to enure them to fatigue and exercise; and they must be frequently led through flocks of sheep, and warrens, to use them to be under command, and to know that they are to run at nothing but what the huntsman orders. They must be carefully instructed each to know his own name, and to understand the voice of the huntsman, and the notes of the horn used in hunting; and finally, to use their own language in a proper manner. When young hounds well know and answer to their names, they should be put into couples, and walked out amongst sheep; and if any be particularly snappish leave the couples loose about their necks in the kennel, till they are more reconciled to them. If any of them should be very troublesome, couple them to old hounds, always avoiding coupling two dogs together, if possible, and taking care that the couples be tight enough to prevent their heads being slipped out of the collar. After being walked out frequently amongst the sheep, they may be uncoupled, a few at a time, and such as offer to run after them should be well chastised; the cry of *ware, sheep*, will afterwards stop them, without further application of the whip; proper attention will soon make them ashamed of it; but if once suffered to taste the blood, it will be difficult to reclaim them. If young and old hounds are aired together, let the former be in couples; they are always ready for mischief, and idleness may induce even the latter to join in it. It may be as well to air the young hounds in that country where they are designed to hunt, as they thus acquire some knowledge of it, and if at any time they should be left behind, they will more readily find their way home. Young hounds should be entered as soon as you can; in woodlands and grasslands, it will of course be earlier than in corn countries. Sport in fox-hunting cannot be said to begin before October; but in the two preceding months, a pack is either made or marred.

## ENTRANCE.

The best time of entering them is about noon; and it should be in a fair warm day; for if they be entered in the morning, they will give out when the heat of the middle of the day comes on, and betake themselves to shady places to rest and sleep. Accordingly it is said that hounds should be entered in the heat of the day, and about October or November, for hare-hunting, the weather being then temperate, and young hares that have not been hunted are then more easily taken for their encouragement. A necessary caution is also added, never at the entering of young hounds to help them to kill the hare with grey-hounds, for this will deter the hounds from putting their noses to the ground, or trying to hunt her themselves. Take the most advanced, that the game may not stand long before them, and let them be well rewarded when all is over. This ought to be repeated at least once a week, for two months successively; by this means they will be so fleshed and seasoned with what game you may enter them at, that they will never afterwards leave off the pursuit. Hounds, after two years old, should be hunted three times a week, if they feed well, and may be kept out the greatest part of the day to try their stoutness. The new hounds should always be entered with the best and staunchest hounds that can be had; and there is not to be one barking dog suffered in the field on this occasion.

Whatever chace the hounds are intended for, it has been said that the hare is the best game to enter them at, because in this chace, they will learn all the turns and doubles that they can possibly meet with in any other kind, and how to come to the hollo. They will learn also from this chace, to have a perfect and nice scent, and hard feet, by being used to highways, beaten paths, and dry hills.

On the other hand, it has been more reasonably maintained, that young hounds should always be entered at their own game; because it is a strange contradiction to enter them at a hare; and then to cut them to pieces for afterwards hunting the hare. This, it is said, is laying a foundation for future cruelty and vexation. Most dogs like that scent best, which they were first blooded to; and if the blood of the fox be of so much service, that of the hare cannot be deemed a matter of indifference. It is, therefore, without doubt most rational to use them to that scent *only*, which it is intended they should hunt. It has been asserted, that the way to render hounds steady from hare, is to encourage them to hunt her. The advantage resulting from this kind of paradoxical practice is said to be, that hounds are thus taught to hunt, and made to learn obedience; but the surer method to make hounds obedient is calling them over often in the kennel, to accustom them to their names, walking them out frequently amongst sheep, hares, and deer, from which they are to be stopped, to make them know a "rate;" and by this practice they will learn obedience. Nature will instruct them how to hunt: art is only necessary to prevent their hunting what they ought not to hunt. Should any young hounds be very fond of hare, let some be found sitting, and started before them, they will soon be checked and cease to run after them. If they are to be steadied from deer, they should often see deer, and they will not regard them. After this probation, a cub should be turned out before them, with some old hounds to lead them on, and they will not long give trouble. After young hounds stoop to a scent, are become handy, know a "rate," and stop easily, put them, a few only at a time, into the pack after the old ones have been hunted and had blood; let them be taken the first day where they are certain of finding. Hounds should be low in flesh when hunting commences; because the ground being generally hard

at that season, they are liable, if lusty, to be shaken. If foxes are plentiful, take the young, with some of the steadiest of the old hounds, where there is least riot, and should you there find a litter of foxes, the young hounds will be so much improved as to need little subsequent instruction. If any cubs be ran to ground, and blood be not then wanted, let them be brought home, and they will be serviceable, should blood be necessary at any time for the young hounds. Frequent hallooing is of use with young hounds, as it keeps them forward, prevents their being lost, and from hunting after the others: the more, therefore, a fox is seen and halloed, the better. Young hounds are thus made eager, and taught to exert themselves. At their first entering, hounds cannot be encouraged too much: when they are handy, love a scent, and begin to know what is right, it will be soon enough to chastise them for doing wrong; in which latter case, one severe beating will save much trouble. The whipper-in should use his voice as well as his whip, when he flogs a hound, and take care that the stroke precedes the "rating;" and he should remember, that the smack of the whip is often as serviceable as the lash to one who has already felt it. The day after young hounds have had blood is a proper time to take them where there is riot, and if they merit it, to chastise them: it is always best to correct them, when they cannot help knowing what they are corrected for. When hounds go out for this purpose, it should be at a late hour; as the worse the scent is, the less inclinable will they be to run it, and the stopping of them will be more easy and immediate. Upon the day when a fox is proposed to be turned out, young hounds should draw small covers and furze brakes, where are hares or deer; a little rating and flogging, before they are encouraged to vermin, teaches them both what they should not and what they should do. A hound that hears a voice which has often rated him, and the whip he has often felt, ought to stop: when hounds are rated, and do not answer the rate, they should be coupled up immediately, and made to know the whipper-in. A most essential point in rendering hounds obedient is to make them understand you; and therefore the language should be appropriate and uniform. Young hounds should be hunted in large covers to tire them out, provided the whipper-in can easily get at them; but when there is much riot there are no openings, the purpose will not be answered, unless you have a body of old hounds to carry on the right scent: for the young hounds, as soon as the ground becomes foiled, will be scattered about the cover, hunting old scents, and will not proceed fast enough to tire themselves. Besides, every fox-hound will leave a bad scent of a fox for a good one of either hare or deer, unless he has been made steady from both. Young hounds are all given to riot; but the better they are bred, the less trouble will they be likely to give: high bred fox-hounds love their own game best: they should have little rest; one day they should be hunted in large covers, where foxes are plentiful; the next, they ought to be walked out amongst hares and deer, and stopped from riot; and the day following, be hunted again as before. By this management young hounds will soon become steady. At first young hounds should be entered to vermin only; and they should be used as early as possible to the strongest and thickest woods and furzes, and they will seldom be shy of them afterwards. By being awed from hare and deer, and being taught to hunt only vermin, hounds will stop at a word, because that word will be understood by them; and a smack of the whip will spare the inhuman trouble of cutting hounds in pieces for faults, which, if entered at hare, they have been invited to commit.

In hare-hunting the hounds, when first entered, must have all the advantages given them that can be. When the hare is put up, from her form, it must be observed which way she went, and the scent must be left to cool a while, and then they must be laid in, and helped as much as can be, by wind, view, hollo, or pricking the passage; nor will it be amiss, for the first time, to give them a hare tired the same morning in her course.

Some are of opinion, that the best way to enter young hounds is, to take a live hare, and trail her upon the ground, sometimes one way, and sometimes another, and then to draw her off to a convenient distance, and hide her, that the dogs, taking the scent, may follow all the traces through which she was drawn, and at length find her.

It has been said, however, that beating the hare up from her seat is a shorter way than trailing her from her feed to her form. Great exactness was formerly observed in the first entering of hounds, not to uncouple them repeatedly in the same sort of ground, lest by being uncoupled constantly in an open field, they would be at a loss what to do when turned into a cover. It was a received opinion, that according to the places where hounds were first entered, they would shew a preference: *e. g.* if entered in a champaign country, they would always hunt better there than in covers, marshy, or mountainous grounds. Hence it was deemed right to use them to every sort of ground, and diversity in the country was strongly recommended, that they might be perfect in all. Some lands, which were of a glutinous and greasy shining mould, never bore any scent, and there the huntsman was to help out the dogs by pricking the hare. In plains and downs where the grass was short, and the scent dried immediately, there also he was allowed to follow his game by the eye, in order to assist the nose of the hounds. Some of the early sportsmen never permitted the hare to be hallooed, or the hounds to be assisted when they were at fault, but suffered them to work it out by themselves; and this, though tedious, was considered a sure way to ascertain the goodness of the hounds: others took all advantages, and killed them as speedily as possible. The method of rewarding the young hounds was curious. The hare, after being laid upon the grass, and bayed by the hounds, was skinned before them; and after the gall and lights were taken away, which were supposed to make the hounds sick, the huntsman, who carried a wallet with bread cut in small pieces, dipped them in the blood, and with the entrails gave them to the hounds; the hare was afterwards distributed, and if any young hound was fearful to come in among the rest, he had the head given him by himself. After this feast, the hounds had bread given them to prevent sickness.

The huntsman ought very well to understand the nature and disposition of his hounds, in finding out the game; for some hounds are of that temper, that when they have found the scent, they will run forward with it, not making any noise, nor shew of the tail; others, when they have found a head, will shew the game; and some, having found the footings of the beast, will prick up their ears a little, and either bark, or only wag their ears, or the hinder part of their bodies. This difference of natural disposition, the huntsman is particularly to observe in the young and newly entered pack, otherwise he will never understand them, nor ever be able to hunt them to any credit or advantage.

For entering the hound at hart or buck, he should be in the prime of grease, for then he cannot stand up, or hold the chace so long. The forest pitched upon should have all the relays at equal distances, as nearly as may be; but then

the young hounds should always have some old staunch ones to enter them, and they should be led to the farthest and last relay, and the hart or buck should be hunted to them. Being come up, the old hounds should be uncoupled; and when they have found the hart, and well entered the cry, then the young ones are to be uncoupled also; and if any of them are found to lag behind, they must be whipped and beaten forward.

In whatever place the hart is killed, the neck should be immediately flayed, and the hounds rewarded; for it is best always to do this while the flesh is hot. Another very good method of entering hounds at the buck, is to take one in the toils or nets, and to wound one of his legs, so as to disable him from running either very swiftly or very far: then let him loose, and first let a blood-hound trace the creature, then let loose all the young hounds; and when they have run down the animal, reward them with the neck.

Some enter their hounds with a toil; but this is a bad way; for the hart being in this case always in fight, and not able to run an end, makes a great number of doubles and turnings: this is very different from the chaces they are to meet with afterwards; and when they find a hart run in the common way, straight forward, and out of sight, they will leave the chace, as unlike that by which they were taught. Daniel's Rural Sports. See HUNTING.

ENTRASME, in *Geography*, a small town of France, in the department of Mayenne; 6 miles S. of Laval.

ENTRAVES, ENTRAVONS, in the *Manege*. See LOCKS.

ENTRE AMBOS OS RIOS, in *Geography*, a town of Portugal, in the province of Entre Minho Douro; 8 miles S.S.W. of Amarante.

ENTRE Minho Douro, a province of Portugal, so called from its situation between the rivers Minho and Douro, bounded on the north by Galicia, a province of Spain; on the east by Trazos Montes and Spain; on the south by the province of Beira, from which it is separated by the Douro; and on the west by the Atlantic ocean; and extending from 40° 50' to 42° N. lat., and from 8° 55' to 7° 55' W. long., being 70 miles in length and 52 in breadth. It contains 963 parishes, 1460 churches, 1130 convents, 6 sea-ports, and 804,000 inhabitants. This is the most northerly, the most fertile, and the most populous territory in the kingdom. Its numerous and fine vallies are shaded by beautiful trees, and watered by limpid streams. Its air is pure and healthy; and it produces corn, wine, oil, and flax in abundance, with a great number of sheep, and plenty of game and fish. The principal towns are Braga, Oporto, Viana, Amarante, Guimaraens, Ponte de Lima, and Pezo de Regna. Its chief rivers are the Minho, Lima, Neiva, Cavado, Ave, and the Douro or Duero, augmented by the Tamega; all of which run westward to the sea.

ENTRECASTAUX, a small town of France, in the department of the Var, near Barjols.

ENTRÉE, *Tr.*, the overture to a ballet, and sometimes the beginning of the dance itself. In the first operas in France, the overture was called the entrée.

ENTREPAS, in the *Manege*, is a broken pace, or going, properly a broken amble, that is, neither walk nor trot, but has somewhat of an amble. This is the pace, or gait, of such horses as have no reins or backs, and go upon their shoulders, or of such as are spoiled in their limbs.

ENTREVEAUX, in *Geography*, a small town of France, in the department of the Lower Alps, chief place of

of a canton in the district of Castellane, with a population of 1326 individuals. It is situated at the foot of the Alps, on the river Var, near Glandeves. N. lat.  $44^{\circ} 1'$ . Its canton has a territorial extent of  $197\frac{1}{2}$  kilometres, eight communes, and 2694 inhabitants.

**ENTRICOMA**, from *ε* and *τριξ*, *hair*, in *Anatomy*, the name of the outer edge of the eye-lid, on which the hairs grow.

**ENTRIES**, amongst *Hunters*, those places in thickets through which deer are found lately to have passed; by means whereof their bigness or size is guessed at; and at which the hounds or beagles are put to them for the view.

**ENTRIES**, *Books of*, in *Law*, are ancient and modern, and contain transcripts of proceedings that have been had in some particular actions; the principal of such are necessary for gentlemen educated to the profession of the law.

**ENTRING a Ship**, in *Sea Language*, the same with boarding her. See **BOARDING**.

**ENTRING-Ladder**, in a *Ship*, is of two sorts; one is used by the ship's sides, in a harbour, or in fair weather, for persons to go in and out of the ship: the other is made of ropes, with small staves for steps, and is hung out of the galley to enter into the boat, or to come aboard the ship from thence, when the sea runs so high that they dare not bring the boat to the ship's side for fear of staving her. See **GANG-WAY**.

**ENTRING-Ropes**. See **ROPE**.

**ENTROCHUS**, in *Natural History*, the name of a genus of fossils of a very regular figure and structure, supposed by many authors to be lapides sui generis, and stones in their native state. They are, however, in reality, the fossil remains of some marine animal, probably either of the echinus, or of the star-fish kind, filled like the fossil species of the echini, with a plated spar. Our imperfect knowledge in the animal history has not yet been able to ascertain to what creature they really belong; but their analogy, with the other animal remains, found in the fossil world, plainly evince, that they are of that origin. They are cylindrical columns, usually about an inch in length, and are made up in a number of round joints, like so many small wheels or segments of cylinders. These joints, when found separate, and naturally loose, as they sometimes are, are called trochitæ. They are all striated, from the centre to the circumference, and have a cavity in the middle, which is sometimes found empty, but more frequently filled up with various matter, of the nature of the stratum, in which they have lain, or of other of the native fossil substances.

The entrochi are composed of the same sort of plated spar with the asterizæ, and the spines and shells of the fossil echini: and this is in these usually of a blueish-grey colour, and very bright and glossy, when fresh broken. They are subject to accidental injuries, like the other extraneous fossils, which have been formed in animal moulds, and are frequently met with compressed, or crooked.

That the entrochi are of marine origin, is evident from this, that they have not unfrequently sea-shells found adhering to them; and when these are broken off, there remain on the entrochi no deficiencies, but the shells themselves shew that they have been formed upon, and have grown to the entrochi, there being always natural hollows in them to answer to that part of the entrochus from which they have been separated; whence it appears very plainly, that these entrochi, however altered since in their substance,

were, however, existing in their present shape, in those very seas where these shells had their growth.

There are not unfrequently found among the entrochi, larger or smaller fragments of plated bodies.

We meet with the entrochi of all the sizes, from that of a pin's head to a finger's length, and the thickness of one's middle finger. They are, in some places, found loose upon ploughed lands; in others, they are lodged in great quantities in the strata of clay, and very often in stones of different kinds, and different hardness.

Mr. Parkinson, in his second volume of "Organic Remains," treats very largely of this class of animals; and Mr. William Martin, in his recent and valuable work, the "Petrificata Derbiensia," has paid considerable attention to the curious remains of this kind which Derbyshire affords: among which he enumerates, 1st, the even-jointed entrochite (*Entrochites lævis*); 2d, the convex-jointed entrochite (*E. prominens*); 3d, the warted entrochite (*E. verrucosus*); and 4th, the ring-jointed entrochite (*E. canulatus*).

Entrochi abound in some particular beds of the first or upper lime-stone rock of the Derbyshire lime-stone or toad-stone series, and from hence the beautiful figured marbles are principally obtained, at Ricklow-dale, Bricks, and High-low, near to Monyash; at Foolow, Calver, Lexley in Ashover, Crick-Cliff, and other places. The three other lime-stone rocks, which lie below the above, contain some few beds with a sprinkling of entrochi in them; but they are very inferior in number or size to those in the upper rock.

Entrochi are also found in small numbers, in the yellow or magnesian range of lime-stone, which traverses the country from Wetherby in Yorkshire to near Nottingham; appears again at Bredon, Cloud's-hill, Barrow-hill, and Gracedieu in Leicestershire; again at Rushall and Walfall; between Wolverhampton and Dudley in Staffordshire; at Abberley in Worcestershire, &c.

The fossil described by Mr. Walcot, in his "Petrifications found near Bath," p. 46, under the name of an entrochus, is more properly a trochus or top-stone, very different from the entrochi of which we have been speaking: it belongs to the Bath free-stone strata.

**ENTROCHO Asterizæ**, the name given by authors to a peculiar kind of entrochus, differing from the common kind, in having a stellar cavity instead of a round one, in its centre.

**ENTROCHUS Pyramidalis**, a name given by some writers to the ortho-ceratites, or tubulus marinus concameratus, a species of shell-fish, not known to us in its recent state, but very common in the stones brought over from Sweden for pavements. Klein. de Tubul. Marin. p. 7. See **TUBULI Concamerati**.

**ENTROCHUS Ramosus**, the name of a fossil body, the several parts of which resemble the entrochi; but as they are joined together in this body when perfect, they shew themselves in their proper light, and a sight of them in this state is sufficient to explode the opinion advanced by some persons, of the entrochi being of a vegetable nature; or, as they have pleased to call them, "rock-plants." The fossil has evidently once been a stella-marina, or sea star-fish, consisting of twenty rays at the extremity of the body. The manner of insertion of these has been this: the body is of a pentagonal figure, and from this there have arisen five rays; these, at their extremity, have been divaricated, each into two, so as to make the number ten in the second progression; and each of these last being again divaricated into two

at its extremity; the third and last progression is of twenty rays. All this is easily distinguishable in the fossil, when perfect, and seems to have been the whole figure of the animal while living. The prototype, or living animal, however, is not found; but this is not an accident peculiar to this fossil, the cornua ammonis, and conchæ anomicæ, with many other bodies that have been once evidently shell-fish, being no where at this time found in their recent state, though so very numerous in the fossile world. This remarkable fossile star-fish is the body called by some authors, *lilium lapidium*. Keppeler's *Epist. ad Klein de Entrochis*.

ENTROCHORUM RADIX. See RADIX.

ENTROPNIUM, (from *εν* and *τροπω*, to turn,) a surgical disease, in which the eyelid turns inward towards the eye, so as to occasion, by the friction and irritation of the eyelashes, chronic ophthalmia, and various inconveniences. See TRICHIASIS.

ENTRUSION, in Law. See INTRUSION.

ENTRY, or ENTRANCE, in its general sense, denotes a door, gate, passage, &c. through which to enter, or arrive within a place.

ENTRY, in Book-keeping. See BOOK-KEEPING.

ENTRY, Bill of. See BILL.

ENTRY, is sometimes also used to denote a duty or impost laid on commodities imported into a state, either by land or sea.

The duties of entry, or importation, are paid according to a tariff settled for that purpose. Where the duty of entry of any commodity is not fixed by the tariff, it is paid by estimation, *i. e.* in proportion to what some other commodity of nearly the same quality and value uses to pay. In making entries inwards, it is usual for merchants to include all the goods they have on board the same ship in one bill, though sometimes there may happen to be upwards of twenty several kinds; and in case the goods are short entered, additional or port entries are now allowed; though formerly the goods so entered were forfeited. As to bills of entry outwards, of including goods to be exported, upon delivering them and paying the customs, you will receive a cocket, which testifies your payment thereof, and of all duties for such goods. If several sorts of goods are exported at once, of which some are free, and others pay customs, the exporter must have two cockets, and therefore must make two entries. Entries of goods, on which a draw-back is allowed, must likewise contain the name of the ship in which the goods were imported, the importer's name, and time of entry inwards. The entry being thus made, and an oath taken, that the customs for these goods were paid as the law directs; you must carry it to the collector and comptroller, or their deputies; who, after examining their books, will grant a warrant, which must be given to the surveyor, searcher, or land-waiter, that they may certify the quantity of goods; after which the certificate must be brought back to the collector and comptroller, or their deputies, and oath made, that the said goods are really shipped, and not landed again in any part of Great Britain. See DEBENTURE, IMPORTATION, and EXPORTATION.

ENTRY, also denotes a solemn reception, or a ceremony performed by kings, princes, ambassadors, legates, &c. upon their first entering a city, or their return in triumph from some expedition.

ENTRY, in Law, signifies the taking possession of lands or tenements by the legal owner, when another person, who hath no right, hath previously taken possession of them. See POSSESSION.

In this case the party entitled may make a formal, but

peaceable entry thereon, declaring that thereby he takes possession; which notorious act of ownership is equivalent to a feudal investiture by the lord (see INVESTITURE); or he may enter on any part of it in the same county, declaring it to be in the name of the whole (Litt. § 417.); but if it lies in different counties, he must make different entries; for the notoriety of such entry or claim to the *parcs* or freeholders of Westmorland, is not any notoriety to the *parcs* or freeholders of Suffex. Also, if there be two disseisors, the party disseised must make his entry on both; or if one disseisor has conveyed the lands with livery to two distinct feoffees, entry must be made on both (Co. Litt. 252.); for as their *seisin* is distinct, so must also be the act which divests that *seisin*. If the claimant be detained from entering by menaces or bodily fear, he may make *claim*, as near to the estate as he can, with the like forms and solemnities; which claim is in force for only a year and a day. (Litt. § 422.) And this claim, if it be repeated once in the space of every year and day (which is called *continual claim*) has the same effect with, and in all respects amounts to, a legal entry. (Litt. § 419, 423.) Such an entry gives a man *seisin*, (Co. Litt. 15.) or puts into immediate possession him that hath right of entry on the estate, and thereby makes him complete owner, and capable of conveying it from himself by either descent or purchase. This remedy by entry takes place in three only of the five species of ouster, *viz.* abatement, intrusion, and disseisin (Co. Litt. 237, 238.); for as in these the original entry of the wrongdoer was unlawful, they may therefore be remedied by the mere entry of him who hath right. But, upon a discontinuance or forfeiture, the owner of the estate cannot enter, but is driven to his action; for herein the original entry being lawful, and thereby an apparent right of possession being gained, the law will not suffer that right to be overthrown by the mere act or entry of the claimant. Yet a man may enter on his tenant by sufferance; for such tenant hath no freehold, but only a bare possession; which may be defeated, like a tenancy at will, by the mere entry of the owner. But if the owner thinks it more expedient to suppose or admit such tenant to have gained a tortious freehold, he is then remediable by writ of entry, *ad terminum qui præterit*. (Co. Litt. 57.) On the other hand, in case of abatement, intrusion, or disseisin, where entries are generally lawful, this right of entry may be *toll'd*, that is, taken away by descent. Descents, which take away entries (Litt. § 385—413.) are, when any one, seized by any means whatsoever of the inheritance of a corporeal hereditament, dies, whereby the same descends to his heir; in this case, however feeble the right of the ancestor might be, the entry of any other person who claims title to the freehold is taken away; and he cannot recover possession against the heir by this summary method, but is driven to his action to gain a legal *seisin* of the estate. In general it appears, that no man can recover possession by mere entry on lands, which another hath by descent. And this title of taking away entries by descent is still further narrowed by the statute 32 Hen. VIII. c. 13. which enacts, that if any person disseises, or turns another out of possession, no descent to the heir of the disseisor shall take away the entry of him that has right to the land, unless the disseisor had peaceable possession five years next after the disseisin. But the statute extendeth not to any feoffee or donee of the disseisor, mediate or immediate. (Co. Litt. 246. 256.) By the statute of limitations it is enacted by statute 21 Jac. I. c. 16, that no entry shall be made by any man upon lands, unless within 20 years after his right shall accrue: and by statute 4 and 5 Ann. c. 16, no entry shall be of force to satisfy the said statute of limitations,

tions, or to avoid a fine levied of lands, unless an action be thereupon commenced within one year after, and prosecuted with effect. Moreover, this remedy by entry must be pursued, according to statute 5 Ric. II. st. 1. c. 8. in a peaceable and easy manner; and not with force or strong hand. For, if one turns or keeps another out of possession forcibly, this is an injury of both a civil and criminal nature. The civil is remedied by immediate restitution; which puts the ancient possessor *in statu quo*; the criminal injury, or public wrong, by breach of the king's peace, is punished by fine to the king. Blackstone's Comm. b. iii. See FORCIBLE Entry.

ENTRY, *writ of*, is a possessory remedy, which disproves the title of the tenant or possessor, by shewing the unlawful means by which he entered or continues possession. (Finch. L. 261.) This writ is directed to the sheriff, requiring him to "command the tenant of the land that he render (in Latin, *præcipe quod reddat*) to the demandant the land in question, which he claims to be his right and inheritance; and into which, as he saith, the said tenant had not entry but by (or after) a disseisin, intrusion, or the like, made to the said demandant, within the time limited by law for such actions; or that upon refusal he do appear in court on such a day, to shew wherefore he hath not done it. This is the original process, the *præcipe*, upon which all the rest of the suit is grounded; wherein it appears, that the tenant is required, either to deliver seisin of the lands, or to shew cause why he will not. This cause may be either a denial of the fact, of having entered by or under such means as are suggested, or a justification of his entry by reason of title in himself, or in those under whom he makes claim; whereupon the possession of the land is awarded to him who produces the clearest right to possess it.

Writs of entry are of divers kinds, distinguished into four degrees, according to which the writs are varied. The first degree is a writ of entry *sur disseisin*, that lieth for the disseisee against a disseisor, upon a disseisin done by himself; and this is called a writ of entry in the nature of an assise. The second degree, by some reckoned the first, is a writ of entry *sur disseisin in le per* and lies against the heir by descent, who is said to be in the *per*, as he comes in by his ancestor; and so it is if a disseisor make a feoffment in fee, gift in tail, &c. The feoffee and donee are in the *per* by the disseisor. The third is a writ of entry *sur disseisin in le per and cui*, where the feoffee of a disseisor maketh a feoffment over to another; when the disseisee shall have this writ of entry *sur disseisin*, &c. of the lands in which such other had no right of entry, but by the feoffee of the disseisor, to whom the disseisor demised the same, who unjustly and without judgment disseised the demandant. (1 Inst. 238.) These three degrees thus state the original wrong, and the title of the tenant who claims under such wrong. If more than two degrees (that is, two alienations or descents) were past, there lay no writ of entry at the common law. For, as it was provided, for the quietness of men's inheritances, that no one, even though he had the true right of possession, should enter upon him who had the apparent right by descent or otherwise, but he was driven to his *writ of entry* to gain possession; so, after more than two descents or conveyances were passed, the demandant, even though he had the right both of possession and property, was not allowed this possessory action, but was driven to his *writ of right*, a long and final remedy, to punish his neglect in not sooner putting in his claim, while the degrees subsisted, and for the ending of suits, and quieting of all controversies. (2 Inst. 153.) But by the statute of Marlbridge, 52 Hen. III. c. 30, it was provided, that when the number of alienations

or descents exceeded the usual degrees, a new writ should be allowed without any mention of degrees at all. Accordingly a new writ, or a fourth, has been framed, called a writ of entry in the *post*, which only alleges the injury of the wrong-doer, without deducing all the intermediate title from him to the tenant; stating it in this manner; that the tenant had not entry unless *after*, or subsequent to, the ouster or injury done by the original disseisor; and rightly concluding, that if the original title was wrongful, all claims derived from thence must participate of the same wrong. Upon the latter of these writs it is (the writ of entry *sur disseisin* in the *post*) that the form of our common recoveries of landed estates is usually grounded. See FINE and RECOVERY.

This remedial instrument of writ of entry is applicable to all the cases of ouster (see OUSTER), except that of discontinuance by tenant in tail, and some peculiar species of forcements. Such is that of forcement of dower, by not assigning any dower to the widow within the time limited by law; for which she has her remedy by writ of *dower, unde nihil habet*. (F. N. B. 147.) See DOWER. But in general the writ of entry is the universal remedy to recover possession, when wrongfully withheld from the owner. It would, therefore, be endless to recount all the several divisions of writs of entry, which the different circumstances of the respective demandants may require, and which are furnished by the laws of England. (See Bracton, l. 4. tr. 7. c. 6. § 4. Britton, c. 114. fol. 264.) Of these the most usual were, 1. The writ of entry *sur disseisin*, and of intrusion (F. N. B. 191. 203.), which are brought to remedy either of the species of ouster. 2. The writs of *dum fuit infra aetatem*, and *dum fuit non compos mentis* (Ibid. 192. 202.) which lie for a person of full age, or one who hath recovered his understanding, after having, (when under age or insane,) aliened his lands; or for the heirs of such alienor. 3. The writs of *cui in vita*, and *cui ante divorcium* (Ibid. 193. 204.) for a woman, when a widow or divorced, whose husband during the coverture hath aliened her estate. 4. The writ *ad communem legem* (Ibid. 207.) for the reversion, after the alienation and death of the particular tenant for life. 5. The writs in *casu proviso*, and in *consimili casu*, (Ibid. 205. 206.) which lay not *ad communem legem*, but are given by stat. Gloc. 6 Edw. I. c. 7. and Weitm. 2. 13 Edw. I. c. 24, for the reversioner after the alienation, but during the life of the tenant in dower or other tenant for life. 6. The writ *ad terminum qui præterit* (Ibid. 201.) for the reversioner, when the possession is withheld by the lessee or a stranger, after the determination of a lease for years. 7. The writ *causa matrimonii prælocuti* (Ibid. 205.) for a woman who giveth land to a man in fee or for life, to the intent that he may marry her, and he doth not: and the like in case of other forcements. These writs are plainly and clearly chalked out in that most ancient and highly venerable collection of legal forms, the "regitrum omnium brevium," or register of such writs as are sueable out of the king's courts, upon which Fitzherbert's "Natura Brevium" is a comment.

In the times of our Saxon ancestors, the right of possession seems only to have been recoverable by writ of entry (Gilb. Ten. 42.); which was then usually brought in the county-court. The proceedings in these actions were not then so tedious, when the courts were held, and process issued from and was returnable therein at the end of every three weeks, as they became after the conquest, when all causes were drawn into the king's courts, and process issued only from term to term, which was found exceedingly dilatory, being at least four times as slow as the other. Hence

a new remedy was invented, in many cases, to do justice to the people and to determine the possession in the proper counties, and yet by the king's judges. This was the remedy by *assise*, which see. Blackl. Comm. b. iii. For other particulars on the subject of this article, see Jacob's Law Dict. by Tomlins.

**ENTRY Island**, in *Geography*, one of the Magdalen islands in the gulf of St. Lawrence. N. lat. 46° 18'. W. long. 61° 20'.—Also, an island in the Pacific ocean, about nine leagues N. from Cape Tierawite and under the same shore, which may be distinctly seen from Queen Charlotte's Sound, at the distance of about six or seven leagues. The name was given to it by lieutenant Cook, who passed it in January 1770.

**ENTYPOSIS**, from *επιποσις*, *I make an impression*, in *Anatomy*, the articulation of the shoulder with the arm.

**ENTZERSTORFF**, in *Geography*, a town of Germany, in the archduchy of Austria; six miles S. of Laab.—Also, a town of Germany, near the conflux of the rivers Reitinpach and Reifenpach; 10 miles W.N.W. of Bruck.

**ENTZERSTORFF** in *Logenthal*, a town of Germany, in the archduchy of Austria; two miles S.E. of Corn Neuburg.

**ENTZERSTORFF** or *Stal-Entzerstorff*, a castellated town of Germany, in the archduchy of Austria, on the north side of the Danube, belonging to the bishop of Freysingen; 24 miles W. of Presburg and nine E. of Vienna.

**ENVERMEU**, a small town of France, in the department of the Lower Seine, chief place of a canton in the district of Dieppe, with a population of 896 individuals. The canton contains 40 communes and 13,402 inhabitants, on a territorial extent of 265 kilometres.

**ENVELOPE**, in *Fortification*, denotes a mount of earth sometimes raised in the ditch of a place, and sometimes beyond it, being either in form of a simple parapet, or of a small rampart bordered with a parapet.

These envelopes are made where weak places are only to be covered with single lines, without advancing towards the field, which cannot be done but by works which require a great deal of room: such as horn-works, half-moons, &c. Envelopes are sometimes called fillons contregards, conserve, lunettes, &c.

**ENVIRON**, among *Military Men*, relates to that complete investment of a town, or fortrefs, which utterly precludes the acquisition of supplies, or of reinforcements, and, in a general sense, may be said to be the basis of a blockade. When we say that a place is environed, we are not indiscriminately to conclude, that any circumvallation has taken place; but, that the country round is so completely possessed by the enemy, as to render any attempt to afford succour to the inhabitants unavailing. Thus, if there be several passes leading to a town situated in a valley, surrounded by mountains inaccessible, or impassable in every part, except at those passes; or if a town stands on a peninsula, of which the isthmus is cut off by the enemy, who likewise possess the navigation of the circumferent waters, such towns are, to all intents and purposes, environed; and, if the blockade be duly supported, must in time surrender merely from a want of supplies.

If, however, the enemy should not be strong enough to keep the inhabitants within close bounds, or if, notwithstanding the whole of the adjacent country may be under his controul, supplies may be attainable from the exterior, whether by connivance among the peasantry, or by the operations of enterprising partizans, then the place cannot be said to be environed. When we consider the many chances arising in favour of such garrisons as make a good

defence, it should appear to be the best policy, as well as the most honourable conduct, to hold out to the very utmost, and never to surrender except under the last extremity. As to being environed, or blockaded, it is sometimes a very important advantage gained by the defending power, because it must prove a complete diversion, by causing a very large force to be occupied in shutting up a comparative hand-full.

It, however, very rarely happens, that towns are, properly speaking, environed: the old system of circumvallation is now obsolete, except in very confined cases, and where there is no army in the field capable of raising the siege. We have, indeed, a recent instance of a large city, namely, Saragossa, having been environed; but it was under most peculiar circumstances; for the place fell rather from a want of an adequate force to cope internally with the assailants, though, on the other hand, the want of supplies was severely felt. If any thing could strengthen the recommendation we have just given, of continuing a defence to the last moment, surely the noble example shewn by that loyal and illustrious, but most unfortunate city, must serve as a stimulus, and prompt every person in charge of a besieged fortrefs, or town, to despise the efforts of the environing army, and to sell every inch of ground at the highest price that valour can impose on a superior force.

Those who undertake a blockade, by completely environing a town, &c. have a most arduous task to perform. They have not only to oppose the sallies of the garrison, but to keep a very sharp look-out against exterior attacks, which may often be so effectually made, by an enterprising partizan, as to coerce a very numerous army to considerable relaxation, such, indeed, as must prove favourable to the defenders. When we consider these circumstances, we shall be less surpris'd at the great losses sustained by besiegers, who, as well as the besieged, suffer under all the disadvantages attendant upon fixed camps; whereby not unfrequently the most destructive diseases are engendered.

**ENVIRONNE'**, in the *French Heraldry*, is when a lion or other figure is environed, or encompassed round with other things. Environné with so many bezants, &c. in orle.

**ENULA**, in *Botany*. See *INULA*.

**ENULION**, from *εν* and *ελευον*, the *gums*, a word used by some medical writers for the flesh of the gums.

**ENUMERATION**, the act of enumerating, or counting. At the time of our Saviour's birth, Augustus Cæsar had commanded an enumeration to be made of all the world, or rather of all the people under his empire: though several able authors are of opinion, that the census, tax, or enumeration mentioned by St. Luke, did not extend to the whole empire, but only to the people of Judæa. See Perizonius de Censu Judaico, and Berger de Viis Militaribus.

At Rome, it was an usual thing to have an enumeration made of all the families: the first of these was under Servius Tullius, when the men amounted to eighty thousand. Pompey and Crassus made another, when they reached to four hundred thousand. That of Cæsar did not exceed one hundred thousand; so that the civil wars must have destroyed three hundred thousand Roman citizens. Under Augustus, in the year 725, the Roman citizens throughout the empire were numbered at four millions sixty-three thousand. In the year of Rome 746, the citizens, being numbered again, were found four millions two hundred and thirty-three thousand. In the year 766, being the last year of Augustus's reign, that prince, together with Tiberius, made another enumeration of the citizens of Rome, when they were found four millions one hundred and thirty-seven thousand persons.

Claudius made a new computation in the year of Christ 48, when, as Tacitus relates it, the Roman citizens throughout the whole empire amounted to six millions nine hundred and sixty-four thousand; though others represent the number as considerably greater. A very rare, yet indisputable medal of Claudius, never yet made public, expresses the precise number in this list made by Claudius, which was called *ostensio*, to be seven millions of people fit to bear arms, beside all the soldiers on foot in the armies, which amounted to fifty legions, fifty-seven cohorts, and sixty soldiers. After this enumeration, we find no more till that of Vespasian, which was the last.

ENUMERATION, in *Rhetoric*, denotes a part of the peroration, wherein the orator, collecting the scattered heads of what has been delivered throughout the whole, makes a brief and artful rehearsal or recapitulation thereof. See RECAPITULATION.

ENUMERATION is also a rhetorical figure: for which see APARITHMESIS.

ENUMERATION of the parts, amounts to the same with what we more usually call distribution. In this part of rhetoric, the orator acquaints his hearers with the several parts of his discourse, upon which he designs to treat. See DISTRIBUTION and PARTITION.

ENUNCIATION, a simple expression or declaration of a thing, in terms either of affirmation or denial.

The schoolmen usually distinguish three operations of the understanding; apprehension, enunciation, and reasoning.

ENUNCIATION, among *Logicians*, denotes the same as proposition.

ENUNCIATION, which, without violation of etymology, might be applied to signify the whole act of speech or delivery of language, is, in conformity with the theory and system laid down under the article ELOCUTION, confined to the utterance and combination of the elements, and the consequent pronunciation of syllables, words, &c. as contradistinguished from the tones, and tuning of the voice, and all that belongs to the melody of speech.

The perfection of enunciation consists in the following particulars; 1. *Distinctness*, or the clear and perfect formation of the respective elements by right motions and positions of the organs of the mouth, accompanied by proper degrees of energy and impulse to impress those elements fully and contradistinctly on the ear. 2. *Articulation*, or the act of combining and linking together of the respective elements, so as to form them into intelligible syllables and words, capable of being again combined into clauses and sentences for the proper conveyance of our ideas, thoughts, and determination. 3. *Implication*, or the combination and apparent union of words in oral utterance, which are graphically separated; and by which, without injury to the intelligible distinctness of the respective words, all differences of auditory impressions are removed between monosyllabic and polysyllabic composition in language.

The faults immediately opposed to distinctness are, 1. *Mumbling*, or an indolence or want of precision in the action of the lips, affecting, of course, principally the labial sounds, but impeding, to a certain degree, the clear progress of the specific impulses given to other elements, by the interior organs of the mouth. 2. *Thickness*, or indolence and imperfection in the action of the tongue, and affecting, more or less, the whole or part of the lingual sounds. 3. *Drawling*, which results from indolence or inaptitude of the whole organs of speech, vocal as well as enunciative. These are defects of lethargy, or deficiency of organic action. Those that follow are of another description. 4. *Mouthing*, a pompous but dull species of indistinctness, which results from affectedly

pursing up the mouth, and consequent drawing the cheeks too close upon, or even between the teeth, during the act of speaking: it is one of the unsuccessful theatrical means of aiming at sublimity and pathos. 5. *Cluttering*, a species of St. Vitus's dance of the organs; hurrying them with too much rapidity and indecision from one elementary position to another, before the respective elements are completely formed, or have had time to make their respective impressions distinctly on the ear. This last is one of the fruitful sources of impediment of speech.

The faults opposed to articulation and implication are, a *sau-ul-ter-r-ing he-c-fi-i-ta-a-tion*, a *pulsative inter-rup-tion*, (such as is almost universally observable in the early reading of school boys, and which some people in their reading never get rid of as long as they live,) and a *pè-dan-tic for-má-li-ty*, such as was ridiculed in a gentleman, who, asking his friend if he came to town in his *cha-ri-ot*, was answered, no, sir, I came in my *co-ach*. But the contradiction, and even opposition, thus marked between distinctness and articulation, though so indispensable to the intelligible treatment of the subject of elocutionary science and instruction, is so little authorized by those who have hitherto treated upon these subjects, that the writer of this article deems it necessary controversially to refer to those authorities, and to state the objections to the customary and confused phraseology which they have sanctioned. Among these, some have defined the term articulation as if it embraced the whole art and practice of enunciative utterance, as the ingenious, and generally speaking, profound and accurate Mr. Gough,—“Articulation,” says he, “is the art of modifying the sounds of the larynx by the assistance of the cavity of the mouth, the tongue, teeth, and lips.” (Manch. Mem. vol. v. pt. ii. p. 645.) But much more frequently it is used as a pure synonym with *distinctness*. (Mr. Sheridan, in his lectures, confounds it not only with distinctness but with enunciation generally, and even with idiomatic pronunciation, Lect. ii. p. 21. 8vo. edit.) But, not to insist particularly upon the important axiom, that the very admission of synonyms is inconsistent with the progress and communication of scientific truth, if such were the use to which the term articulation were to be applied, why did the English grammarian go to the Greek language and to the science of anatomy to borrow a name for an idea which he had already a good and familiar English word fully and completely to convey? How came he to apply that word so superfluously borrowed in a sense diametrically opposite to that which it bears in the science from which it is taken? For articulation in anatomy signifies the *junction of bones*, or that flexible combination of joints or elementary portions into a limb, or of limbs into a body, by which the unity of the whole is constituted, without injury to the individuality of the parts. And lastly, how came he to look out for a supernumerary name to one idea, while another idea equally indispensable to his science (for the combination of elements is as necessary to speech as their formation) without any separate or specific designation? Without going further, therefore, into critical disquisition, we may venture to lay down, as one of the canons of elocution and grammatical nomenclature, the following definition.—Articulation (as one of the essential properties of human enunciation, is the jointing or linking together of the respective elements, and syllables, and words (the portions, limbs, and members of sentences) as the bones themselves, (the portions, limbs, and members of the anatomical frame) are linked or jointed together, by an analogous articulation in animal economy. Implication will then remain to be considered merely as that part of articulation which relates separately to the articula-

tion of separate graphic words in the act of oral delivery, and consequently as indicating rather a grammatical distinction, than a distinct species or modification of organic action: for in well delivered speech (it is contended, by the authority so frequently referred to in the different articles relative to elocution) the ear, unassisted by the memory of the eye, knows of no such thing as a division or distribution of speech into such separable portions as in graphic composition are denominated words. The process of enunciation and implication consists in a delicate precision of the motion of the organs, without cessation of sound, from one elementary position to another, by which the termination of the perfect sound is glided more or less intimately into the succeeding element or commencement of the ensuing syllable. Thus literal sounds, intimately glided into each other, are articulated into syllables; as, *a* and long *l* into *all*. Syllabic sounds, intimately glided into each other, are articulated into words; as, *all* and *ways* into *always*. The terminations of words (as they are called in conformity with graphic distinctions) glided into the initial sounds of succeeding words, are implicated into clauses, or parts of clauses; as the man, a ship, an apple,

Harry to Harry might, and horse to horse, &c.

A good enunciation, then, consists in that clear and accurate delivery of verbal language, by which the requisite qualities of distinctness and articulation are combined and modified; and the due proportions and alterations of sound and interruptions, constituting the specific relations of letters, syllables, members, clauses, and sentences, are preserved in discourse or reading.

ENUNCIATIVE ORGANS, those portions and members of the human mouth, by the motions, positions, and contact of which, specific character is superadded to the original impulses of voice, so as to render them communicable signs of distinct ideas. See ORGANS of Speech.

ENVOICE. See INVOICE.

ENVOY, a public minister sent by one sovereign prince or independent state to another to negotiate some affair, or to watch over the interests of that state or prince in general, and furnished with the credentials of an envoy. Like ambassadors, envoys may be either *ordinary*, who reside permanently at the court of a foreign prince, or *extraordinary*, who are dispatched for one particular purpose, and retire when their mission is accomplished. Envoys hold the second rank among public ministers sent to foreign courts: but they are alike under the special protection of the law of nations, and enjoy all the privileges and immunities of ambassadors, except those relating to the ceremony of their reception, public entry, and solemnity of their audiences. See EMBASSADOR.

The quality of envoy extraordinary, Wicquefort observes, is very modern; more modern than that of resident: the ministers invested therewith, at first, took on them most of the airs of ambassadors; but they have since been taught otherwise.

In the year 1639, the court of France made a declaration, that the ceremonies of conducting envoys extraordinary to their audience in the king and queen's coaches, with divers others, should no longer be practised to envoys.

S. Justiniani, the first envoy extraordinary from Venice, after that regulation, offered to cover in speaking to the king, but it was refused him; and the king of France himself declared, that he did not expect his envoy extraordinary at the court of Vienna should be regarded any otherwise than as an ordinary resident. Since this time, those two kinds of ministers have been treated alike. Wicquefort.

ENURE, in *Law*, signifies to take place, or be available, and is as much as to have effect. Thus for instance, a release made to tenant for life shall enure, and be of force and effect to him in the reversion.

ENURESIS, in *Medicine*, from *en* and *ὄστρος*, *mingendi astus*, the nosological term for incontinence of the urine. See URINE, incontinence of.

ENVY, in *Ethics*, is defined by Mr. Locke to be an uneasiness of mind, occasioned by the consideration of a good we discover in possession of another person, whom we deem less worthy of it than ourselves. It is a composition of sorrow and hatred, and stands in direct opposition to congratulation. Otherwise, envy entertains a degree of sorrow that the good contemplated should escape ourselves, and of anger that it should fall to the share of another. Or, it is that species of malevolence which is inspired by the conjoined influence of pride, sorrow, and anger. It differs from *emulation* (which see), or a disquiet, occasioned by the felicity of another, not because he enjoys it, but because we desire the like for ourselves; as it occasions an uneasiness not merely from the want of the felicity possessed by another, but because he enjoys it. Envy, in its nature and effects, is the basest, most mischievous, and most tormenting of all passions. Aristotle (*De Rhetor.* l. ii. c. 12.) observes, that this passion most usually affects persons who were once upon a level with those they envy. The method prescribed by Cicero (*De Orat.* l. ii. c. 52.) for lessening or removing the influence of this passion is to shew that the things which occasioned it, have not happened to the envied person undeservedly; but are the just rewards of his industry or virtue; that he does not so much convert them to his own profit or pleasure, as to the benefit of others; and that the same pains and difficulties are necessary to preserve them, with which they were at first acquired.

ENVY, in *Mythology*, is represented by the Greek and Roman poets as an infernal divinity, with squinting eyes, lean body, pale countenance, disturbed air, head encompassed with serpents, &c.

ENURNY, is the *herald's* term for the bordure of a coat of arms being charged with any kind of beasts.

ENXYLON, of *en* and *ξύλον*, *wood*, a name used by the Greek authors for a species of worm or maggot, hatched from the egg of a beetle, and having its habitation in wood; which, in this state, it erodes and burrows into, in various directions. The old Greeks called it also *dex* and *thrips*, and used the pieces of wood eroded by it in remarkable figures, as seals. See THRIPS.

ENY, SAINT, in *Geography*, a small town of France, in the department of La Manche; 9 miles S. W. of Carantan.

ENYDRA, in *Botany*, (*ενυδρος*, *living in the water*), a Syngenesious genus of Loureiro's *Fl. Cochinch.* 510, which appears to belong to the 4th section of Jussieu's *Corymbifera*, and to the order *Polygamia-segregata* of Linnæus. The character is, Common Calyx of four leaves; partial of one leaf, rolled up into a tube, single-flowered. Corollas all tubular; those of the radius three-cleft. Receptacle naked. Down none. The species is *E. fluvians*, a native of the marshes of Cochinchina, with opposite, serrated, rather hastate leaves, and a white terminal flower. We know not whether it be reducible to any previously-described genus.

ENYSTRON, of *en* and *ὄστρος*, *posterior*, a word used by Aristotle for the second ventricle in ruminating quadrupeds, in which the food is elaborated and concocted.

ENZ, in *Geography*, a river of Germany, which rises about 10 miles W. of Altenstadt, in the circle of Swabia,

passes by Wildbad, Neuenburg, Pfortzheim, &c., and joins the Neckar at Bessigheim, in the duchy of Wurtemberg.

ENZELLI. See EINZELLE.

ENZIG, a lake of Germany, in the circle of Upper Saxony, and new mark of Brandenburg; 12 miles W.S.W. of Dramberg.

ENZINAS, FRANCIS, in *Biography*, was born at Burgos, in Spain, about the year 1515. In Moreri and other works he is known by the name of Dryander, which is a Greek translation of his family name. He was educated in Germany, and became a zealous disciple of Melancthon, who thought very highly of his talents, and wrote a letter in his favour to archbishop Cramer in the year 1548. He published a Spanish translation of the New Testament, which he dedicated to the emperor Charles V.; and which drew down upon him the vengeance of the higher powers, and he suffered an imprisonment of 15 months duration. He escaped in the year 1545, and went to Calvin, who resided at Geneva. He published "A history of the State of the Low Countries, and of the Religion of Spain," which is very rare, and forms a part of the "Protestant Martyrology," printed in Germany.

ENZINAS, JOHN, brother of the former, resided a considerable time at Rome, and became a convert to the protestant religion, and was setting out for Germany to join his brother John, when some expressions which he dropped, relative to the corruptions and disorders of the church, occasioned his being accused of heresy, and thrown into prison. The terrors of a dungeon, and the prospect of a cruel death, did not daunt his noble soul, but when brought before the pope and cardinals to be examined, he refused to retract what he had said, and boldly avowed and justified his opinions, for which he was condemned to be burnt alive; a sentence which was put into execution at Rome in the year 1545. Moreri, under the word Dryander.

ENZOWAN, in *Geography*, a town of Bohemia, in the circle of Leitmeritz; four miles E. of Leitmeritz.

EO, EU, or *Miranda*, a river of Spain, which rises in the mountains of Asturias, separates the province of Asturias from Galicia, and runs into the Atlantic, a little to the north of Rivadeo.

EOA, in *Ancient Geography*, a town of Africa Propria, according to Ptolemy; called Oea by Mela.

EOBANUS, HELIUS, in *Biography*, an eminent Latin poet, was born, in 1488, on the confines of Hesse; hence he obtained the name of Hessian. His parents were so poor, that it has been said he was born in the open air under the shade of a wide spreading tree; but his education was not neglected. He was taught Latin at a small school, and pursued his more advanced studies at the university of Erfurt, where he afterwards taught the belles lettres till the year 1526, when Philip Melancthon procured him an invitation from the city of Nuremberg. Here he taught for seven years and then returned to Erfurt, where his reputation was so high and so firmly established, that he is said to have had 1500 scholars at a time. His fame produced him but very trifling emoluments, and he was often labouring under the greatest poverty. He at length obtained through the interest of Philip, landgrave of Hesse, a good situation at the university of Marburg, where he died on the 5th of October 1540. Camerarius, who wrote his life, praises his good qualities, his application to labour, and his talent at poetry. He was a man of great good nature, sincere in his attachments, and averse from contention. He took credit to himself for being a hard drinker, and would challenge any man as to the quantity of liquor which he would

drink, and in a contest of this kind his antagonist fell dead on the floor. He wrote many books, a list of which is given by Moreri: his poems and epistles have been frequently published. Moreri.

EODANDA, in *Ancient Geography*, a desert island, situated E. of Arabia Felix.

EOLIAN, in *Ancient Music*. The Eolian tone or mode was one of the mean or principal modes of the Greek music, and its fundamental sound was immediately above the Phrygian.

The Eolian mode was grave, according to Latus. "I sing (says he) Ceres and her daughter Melibæa, the spouse of Pluto, upon the Eolian mode, full of gravity."

The name of Eolian, given to this mode, is not derived from the Eolian isles, but from Eolia, a country of Asia Minor, where it was first used.

EOLIC, or rather *Æolic*. See *ÆOLIC*.

EOLIPILE. See *ÆOLIPILE*.

EOLUS, and *EOLUS's harp*. See *ÆOLUS*.

EON, or *ÆON*. See *ÆON*.

EON, a word used by some anatomical writers to express the whole ambit or compass of the eye.

EON, DE L'ETOILE, in *Biography*, a French fanatic, who, from the resemblance of his name to the word *eum*, applied to himself this passage, "per Eum qui venturus est judicare vivos et mortuos," and was satisfied that he was the person alluded to, viz. the son of God. This doctrine he taught with much fervour, and succeeded, like other enthusiasts, in making many converts, who gave him the homage due to one on whom their future destiny depended. At Rheims he drew down the notice of the clergy, who caused him to be apprehended, and after an examination he was committed to prison, where he languished a few days, and miserably died. Many of his adherents persisting in the same follies which had characterized their master, were apprehended, and, refusing to abjure their errors, were delivered over to the secular power, and were burnt alive in the neighbourhood of Rheims. Such was the persecuting spirit of the priests who never fail to abuse the power entrusted to them, and who would, in this instance, have been better employed in instructing their own flocks than in murdering these deluded fanatics. Moreri.

EOOA. See *EA-OO-WEE*.

EORDÆA, in *Ancient Geography*, a country of Macedonia, in Mygdonia.

EORIA, in *Mythology*, a feast celebrated by the Athenians in honour of Erigonus, who, by way of punishment, for their not avenging the death of his father Icarus, engaged the gods to inflict the curse on their daughters, that they should love men who never returned their passion. The feast was instituted by the order of Apollo.

EOSTRE, a Saxon goddess, to whom they sacrificed in the month of April, called the month of Eostræ; and thence the name Easter, which the Saxons retained after their conversion to Christianity, applying it to the festival celebrated in commemoration of our Saviour's resurrection. Bed. de Rat. Temp. cap. 13.

EPACRIA, in *Ancient Geography*, a town of Greece, in Attica.

EPACRIS, in *Botany*, from *επι*, upon, and *ακρῖς*, the summit of a mountain, alluding to the native situation of several of the species. Mountain-blossom. Forst. Gen. t. 10. Linn. Suppl. 19. Schreb. 113. Willd. Sp. Pl. v. 1. 834. Mart. Mill. Dict. v. 2. Gärtn. t. 94. Class and order, *Pentandria Monogynia*. Nat. Ord. *Erica*, Juss.

Gen. Ch. *Cal.* Perianth of several imbricated, ovate, acute leaves; the five innermost longest and equal. *Cor.*

of one petal, funnel-shaped; tube dilated upwards; limb in five equal, ovate, spreading segments. Nectary of five obovate blunt scales, closely surrounding the base of the germen. *Stam.* Filaments five, equal, very short, inserted into the summit of the tube of the corolla; anthers incumbent, roundish oblong, of two cells and two lobes, bursting longitudinally, destitute of any appendage. *Pist.* Germen superior, roundish, with five furrows; style cylindrical, rather shorter than the tube; stigma capitate. *Peric.* Capsule roundish, somewhat depressed, with five furrows, of five valves and five cells, the partitions from the centres of the valves. *Seeds* numerous, minute, angular, affixed to the central column.

*Eff. Ch.* Calyx imbricated. Corolla tubular. Stamens inserted into its orifice. Scales five, at the base of the germen. Capsule superior, of five cells and five valves, with partitions from their middle. Seeds numerous, chaffy.

The numerous species of this elegant genus, but few of which have, as yet, found their way into botanical books, are all natives of New Holland or New Zealand. They bear a general resemblance to the vast Cape genus *Erica*, with which botanists have associated them in natural order, not without some uncertainty. Willdenow enumerates but four species, of which the finest is *E. grandiflora*, Sm. *Exot. Bot. v. 1. 75. t. 39.* *Curt. Mag. t. 982.* (*E. longiflora*; *Cavan. Ic. v. 4. 25. t. 344.*) "Leaves heart-shaped, pungent, recurved, on footstalks. Flowers pendulous." Native of dry sandy places in New South Wales, flowering in October. Its chief beauty consists in its copious long pendulous flowers, with a crimson tube and white border.

To these are now added, *E. obtusifolia*, Sm. *Exot. Bot. v. 1. 77. t. 40.* "Leaves elliptic-lanceolate, very obtuse, and pointless, on short footstalks. Flowers drooping toward one side." Grows in a sandy soil near Port Jackson, New South Wales, blossoming in October. The flowers are cream-coloured, with a brownish calyx.

*E. pulchella*, *Cavan. Ic. t. 345.* *Curt. Mag. t. 1170.* Branches clothed with rusty down. Leaves heart-shaped, recurved, pungent. Flowers axillary, crowded. Native of Port Jackson. Flowers white, sweet-scented.

*E. pungens*, *Cavan. Ic. t. 346.* Branches smooth. Leaves ovate, pungent. Flowers axillary, crowded. Tube cylindrical. Common about Port Jackson. The flowers are copious, large, snow-white, and very fragrant, resembling those of a *Phlox* in size and figure. Cavanilles' plate, a truly miserable representation of this magnificent species, misled Dr. Sims in *Curt. Mag.* to confound it with the last. We apprehend this last writer has committed a further error in taking the red-flowered species, represented in his *t. 1199*, for a variety of the *pungens*. They seem to us very distinct.

Forster and Cavanilles confounded with the genus of *Epacris* that of *Styphelia*, whose fruit is a drupa, with five seeds.

EPACTHES, *Ἐπαχθῆς*, in *Antiquity*, a festival celebrated in honour of Ceres, named *Ἀχθῆα*, from *ἄχθος*, *i. e.* grief, in memory of her sorrow, when she had lost her daughter Proserpine.

EPACTS, in *Chronology*, the excesses of the solar month above the lunar synodical month; and of the solar year above the lunar year of twelve synodical months; or of several solar months above as many synodical months; and several solar years above as many dozen of synodical months.

The epacts, then, are either *annual* or *menstrual*.

EPACTS, *Menstrual*, are the excesses of the civil or calendar month above the lunar month.

Suppose, *e. gr.* it were new moon on the first day of January; since the lunar month is 29 days, 12<sup>b</sup> 44<sup>b</sup> 3<sup>o</sup>; and

the month of January contains 31 days; the menstrual epact is 1 day 11<sup>b</sup> 15<sup>b</sup> 57<sup>o</sup>.

EPACTS, *Annual*, are the excesses of the solar year above the lunar.

Hence, as the Julian year is 365 days 6', and the Julian lunar year 354 days 8' 48' 36", the annual epact will be 10 days 21<sup>b</sup> 11<sup>b</sup> 22<sup>o</sup>; that is, nearly 11 days. Consequently, the epact of two years is 22 days; of three years, 33 days; or rather three, since 30 days make an embolismic, or intercalary month.

Thus the epact of four years is 14 days, and so of the rest; and thus, every 19th year the epact becomes 0; consequently, the 20th year the epact is 11 again; and so the cycle of epacts expires with the golden number or lunar cycle of 19 years, and begins with the same, as in the following table; which is formed by the constant additions of 11, casting off 30; supposing the lunar month to consist of 29 and 30 days, and the civil year of 365 days, with a bissextile every fourth year. This natural order of the epacts is such as was established by the council of Nice, A.D. 325.

Gold. Numb.	Epacts.	Gold. Numb.	Epacts.	Gold. Numb.	Epacts.
1	XI	7	XVII	13	XXIII
2	XXII	8	XXVIII	14	IV
3	III	9	IX	15	XV
4	XIV	10	XX	16	XXVI
5	XXV	11	I	17	VII
6	VI	12	XII	18	XVIII
				19	XXIX

Again, as the new moons are the same, that is, as they fall on the same day every 19 years, so the difference between the lunar and solar years is the same every 19 years. And because the said difference is always to be added to the lunar year, in order to adjust or make it equal to the solar year; hence the said difference respectively belonging to each year of the moon's cycle is called the "epact of the said year," that is, the number to be added to the said year, to make it equal to the solar year, the word being formed from the Greek *ἔπαχος*, *induco*, *intercalo*.

Upon this mutual respect between the cycle of the moon and the cycle of the epacts, is founded this rule for finding the Julian epact, belonging to any of the moon's cycle. Multiply the year given of the moon's cycle into 11; and if the product be less than 30, it is the epact sought; if the product be greater than 30, divide it by 30, and the remainder of the dividend is the epact. For instance, we would know the epact for the year 1712, which is the third year of the moon's cycle. Wherefore 3 is the epact for 1712, for  $11 \times 3 = 33$ , and 33 being divided by 30, there is left three of the dividend for the epact. But the difference of the Julian and Gregorian years being equal to the excess of the solar above the lunar year, or 11 days, it happens that the Gregorian epact for one year is the same with the Julian epact for the preceding year.

By the help of the epact may be found what day of any month in any year the new moon falls on, thus: to the number of the month, from March inclusively, add the epact of the year given: if the sum be less than 30, subtract it out of 30; if greater, subtract it out of 60; and the remainder will be the day whereon the new moon will fall.

If the new moon be sought for in the month of January or March, then nothing is to be added to the epact; if for February or April, then only one is to be added.

## EPAMINONDAS.

Thebes was taken by the Lacedæmonians, and Pelopidas with others attached to liberty and independence were expelled, but Epaminondas was suffered to remain, as one whose poverty and philosophy would prevent him from taking any part in political concerns. When the exiles, about four years afterwards, regained the city, they were joined by Epaminondas, and the Thebans regained their liberty. These two friends concurred in improving the military discipline of their fellow-citizens; and Epaminondas in particular took pains by his counsel and example, in promoting among them that frugality and contempt of pleasure which lie at the foundation of all manly exertions. By such conduct he gained the confidence of the Thebans, and being raised to a high rank in the army, he was deputed as a delegate to Sparta for the purpose of negotiating a peace. On this occasion, when the other deputies were overawed by Agesilaus, who guided the operations of the Lacedæmonians, Epaminondas asserted the dignity of his character as the representative of an independent state, and insisted that the Thebans should retain the same authority in Bœotia with that of the Spartans in Laconia. The Spartan king was incensed, and war was immediately declared against the Thebans. The Lacedæmonians gave orders to their king Cleombrotus, to march into Bœotia at the head of an army consisting of 10,000 foot soldiers and 1000 horse. The army of the Thebans was made up of only 6000 infantry and a small body of cavalry; but Epaminondas commanded it, and under him was Pelopidas. The two armies met at Leuctra, a small town of Bœotia, and on the 8th of July, B.C. 371, a battle was fought, which by the wisdom and valour of Epaminondas terminated in the defeat of the Lacedæmonians, and the death of Cleombrotus. It afforded singular satisfaction to the victorious general that his father and mother had lived to witness the glory he now acquired. Two years after (B.C. 369) Epaminondas and Pelopidas were nominated Bœotarchs, or chiefs of the Bœotian league. The concurrence of circumstances, mutual esteem, friendship, and an uniformity of sentiments and views, formed an indissoluble union between these two great men. With Pelopidas, the companion of his labours and his glory, Epaminondas entered Peloponnesus, spreading terror and desolation through the states in alliance with Lacedæmon, hastening the defection of others, and breaking the yoke under which the Messenians had groaned for centuries. Seventy thousand men of different nations marched under his orders with an equal confidence, and he led them on to Lacedæmon. Agesilaus, apprised of his approach, was anxious and alarmed; but such was his resistance, and the delay occasioned by it, that Epaminondas thought it most prudent to retreat. After quitting the Spartan territories, he rebuilt the ancient city of Messene, and recalled its dispersed inhabitants from the surrounding countries, in which they had long lived as aliens. It was the established rule of the Bœotian league, that the chiefs should hold their office only for a year, and then resign to their successors. Epaminondas and Pelopidas, however, retained their authority four months longer than the term prescribed by law. For this they were accused, and judicially prosecuted. Pelopidas pusillanimously sunk under the charge; but Epaminondas appeared before his judges with the same tranquillity as at the head of his army, and thus addressed them: "The law condemns me, I merit death, I only demand that this inscription be engraven on my tomb: the Thebans have put Epaminondas to death, because at Leuctra he forced them to attack and vanquish those Lacedæmonians, whom they did not before dare to look in the face; because his victory saved his country, and restored liberty to Greece;

because under his command the Thebans besieged Lacedæmon, which deemed herself too fortunate to escape from ruin; and because he rebuilt Messene, and surrounded it with strong walls." The people present applauded this speech, and the judges did not dare to condemn Epaminondas. In the next year Epaminondas marched again into Peloponnesus to aid the Arcadians against the Spartans; and having taken some towns and laid waste the country, he marched to Corinth, which was successfully defended against him. Upon his return, so uncertain is popular favour, he was deprived of his command, and reduced to the condition of a private citizen. After some time, an army being sent to rescue Pelopidas, who had been seized and imprisoned by the tyrant Alexander the Phœæan, Epaminondas served in it as a private soldier, and in that humble rank preserved the army from being utterly destroyed. His fellow-citizens reinstated him in his command, and sent him with fresh forces to recover his friend, whose life was supposed to be in imminent danger. Alexander was so intimidated that he acquiesced in a cessation of arms, on condition of releasing Pelopidas and another deputy. Thebes had now arrived at such a degree of importance among the Grecian states, as to be preferred to Sparta and Athens by the Persians, who, therefore, wished to enter into a treaty with the Thebans. Pelopidas concluded the treaty, though the Theban allies demurred against it. Epaminondas was therefore deputed with an army to force the Achæans to continue the alliance; and in this business he succeeded, and a general peace soon followed. Epaminondas wished to render his country as powerful by sea as it was by land; and with this view he was deputed to negotiate with the Rhodians, Chians, and other maritime people. The Thebans were still pursuing their ambitious designs; and Epaminondas marched a powerful army into Peloponnesus: but, as a confederacy was formed against the Thebans, the troops of which assembled at Mantinea, Epaminondas, apprehending that Sparta would be left defenceless, made a sudden march in order to surprise it. But Agesilaus was ready to receive him. Informed by a deserter of Epaminondas's march, he returned home with extraordinary celerity, and placed his soldiers in the most important stations. The Theban general ordered several attacks. He had penetrated to the forum, and made himself master of one part of the city, when Agesilaus, then near 80 years of age, listening only to the dictates of despair, rushed into the midst of danger, and seconded by the brave Archidamus his son, repulsed the enemy and compelled them to retire. Epaminondas was not molested in his retreat; but a victory was become necessary, that the failure of his enterprise might be forgotten. He therefore marched suddenly to Mantinea, expecting to find it unguarded; but here he was disappointed. He determined, however, to risk a battle for the purpose of retrieving his honour. The army of the Lacedæmonians and their allies consisted of more than 20,000 foot and near 2000 horse; the army of the Theban league of 30,000 infantry and about 3000 cavalry. Never did Epaminondas display greater abilities than on the present occasion; so that the enemy, dismayed at his appearance, betook themselves to flight. But whilst he was pursuing them with great ardour, they suddenly rallied, and poured upon him a shower of darts. At length one of them pierced his breast with a javelin, the point of which was left in his body. When he was carried off the ground to his tent, and had recovered his speech, his first question was, what was become of his shield? when it was brought him, he kissed it as the instrument of his labours and his glory. He then inquired concerning the event of the battle; and being in-

formed

formed that the Thebans were victorious, he said, "It is well; I have lived long enough;" or, as others report his declaration, "I die unconquered. Advise the Thebans to conclude a peace." The javelin being then extracted, he expired, B. C. 363. Epaminondas was never married; and he seems to have regarded celibacy as most favourable to his philosophical pursuits in private life, and to his active services in a public station. On the plain where he fell, two monuments were raised to him, *viz.* a trophy and a tomb. Epaminondas is represented by Cicero as one of the greatest men that any age or nation ever produced: and why, it is said, should we not grant this honourable distinction to the general who perfected the art of war, who eclipsed the glory of the most renowned commanders, and who was never vanquished but by fortune; to the statesman, who gave to Thebes a superiority she had never possessed, and which she lost immediately upon his death; to the negotiator who, in the general assemblies and congresses of Greece, always maintained a superiority over the other Grecian deputies, and found means to retain in the alliance of Thebes, his country, even the states who were jealous of the growth of this new power; to the man who equalled in eloquence the greater part of the Athenian orators, was no less devoted to his country than Leonidas, and perhaps more just even than Aristides? Travels of Anacharsis, vol. ii. Corn. Nep. Vit. Epam. Plutarch Vit. Pelop. & Agesil. Univ. Hist. vol. v. and vi.

**EPANALEPSIS**, *Επαναληψις*, called also *Epanadiplosis*, in *Rhetoric*, the repetition of the same word in the beginning of one sentence, and at the end of another. Thus Virgil,

"Ambo florentes ætatis, Arcades ambo."

Such also is the expression of Plautus (*Amph. Act. ii. Sc. 2. v. 21.*): "Virtue contains all things: he wants no good thing who has virtue." The figure is the same, though the principle is less honest, which occasions the advice given by the writer in Horace, (*Epist. i. 1. 65.*) "Get money, if you can, honestly; but, however, get money." This figure adds force to an expression, when the principal thing designed to be conveyed is thus repeated, so as to leave its impression last upon the mind. And the beauty is heightened, when the sentence has an agreeable turn arising from two opposite parts; as in Cicero's compliment to Cæsar, (*Pro Marcell. c. 6.*): "We have seen your victory terminated by the war: your drawn sword in the city we have not seen." Hermogenes (*Sturm. de Univers. Eloc. p. 410.*) calls this a *circle*, because the sentence returns again to the same word. See *ANADIPLOSIS*.

**EPANAPHORA**, *Επαναφορα*, the same with anaphora.

**EPANA'STASIS**, (from *επι*, and *αυσισημι*, to excite,) in *Surgery*, a tumour, or tubercle.

**EPANASTROPHE**, *Επαναστροφη*, in *Rhetoric*, the same with what is otherwise called anadiplosis.

**EPANCYLOTUS**, (from *επι*, and *αγκυλος*, crooked), in *Surgery*, a bandage described by Oribasius.

**EPANODOS**, *Επανοδος*, in *Rhetoric*, an inversion of a sentence, or a repetition of the same words in an inverted order; thus:

"Nox brevis nimis, ah! nimis brevis nox." Voss. *Rhet. lib. v. p. 298.*

This figure comprehends both *anadiplosis* and *epanalepsis*; for it both begins and ends with the same word, and the same word is likewise repeated in the middle. This turn of expression has a beauty in it, and shews a readiness of thought. Minutius Felix has given an example of it, when he is exposing the folly of the Egyptian superstition. "Isis," says he, "with Cynocephalus, and her priests,

laments, bemoans, and seeks her lost son; her attendants beat their breasts, and imitate the grief of the unhappy mother: in a little time the son is found, upon which they all rejoice. Nor do they cease every year to lose what they find, or to find what they lose. And is it not ridiculous to lament what you worship, or to worship what you lament?" This figure serves likewise to illustrate and enforce the sense by setting it in two opposite views. Such is the expression of the prophet (*Is. v. 10.*) "Wo unto them, who call good evil, and evil good: who put darkness for light, and light for darkness."

**EPANORTHOSIS**, or **CORRECTION**, in *Rhetoric*, a figure by which the orator revokes and corrects something before alleged, as too weak, and adds something stronger and more conformable to the passion by which he is agitated.

The word is formed of *ορθος*, right, straight; whence *ορθωω*, I straighten; *ανορθωω*, *επανορθωω*, I redress, straighten, correct, and *επανορθωσις*, correction. Accordingly the Latins call it *correctio* and *emendatio*.

This figure is used in different ways. Sometimes one or more words are recalled by the speaker, and others substituted in their room. At other times, without recalling what has been said, something else is introduced as more suitable, instances of both kinds follow.

Such, *e. gr.* is that of Cicero for Cælius: "O stultitia! stultitiamne dicam, an impudentiam singularem? Oh folly! folly did I call it, or rather intolerable impudence?" And in the first *Catilinarian*: "Quamquam quid loquor? Te ut ulla res frangat? Tu ut unquam te corrigas? Tu ut ullam fugam meditare? Tu ut ullum exilium cogites? Utinam tibi istam mentem dii immortales donarent." Thus also Terence, in the *Heautontimo-rumenos*, introduces his old man Menedemus, saying,

"Filium unicum adolescentulum

Habeo. Ah! quid dixi habere me? imo habui, Chreme. Nunc habeam necne, incertum est." "I have an only son, Chremes. Alas! did I say, that I have? I had indeed; but it is now uncertain, whether I have or not."

Cicero, in his defence of Milo, speaking to the judges concerning Clodius says; "Are you only ignorant, what laws, if they may be called laws, and not rather torches and plagues of the state, he was about to impose and force upon us?" Again, in his defence of Plancius he says: "What greater blow could those judges, if they are to be called judges, and not parricides of their country, have given to the state, than when they banished him, who, when prætor, freed the republic from a neighbouring war, and when consul from a civil one?" Here he is speaking of Opimius: but in commending the moderation of Lucius Mummius who did not enrich himself, but his country, by demolishing the wealthy city of Corinth, he thus recalls his whole expression, and by giving it a new turn, heightens the compliment he designed him. "He chose rather," says he, "to adorn Italy, than his own house, though by adorning Italy his house seems to have received the greatest ornament." *De Off. l. ii. c. 22.* Sometimes the correction is made by substituting something contrary to what had been said before: as in the following passage of Cicero (*Philipp. iii. c. 2.*): "Cæsar" (meaning Augustus), "though but a youth, by an incredible and surprising resolution and courage, when Antony was most enraged, and we dreaded his cruel and pernicious return from Brundisium, at a time when we neither asked, nor expected, nor desired it (because it was thought impossible) raised a very powerful army of invincible veterans, to effect which he threw away his whole estate. Although I have

used an improper word; for he did not throw it away, but employed it for the safety of the government." At other times, as we have before observed, the correction is made by adding a more suitable word, without any repetition of the former. Thus Cicero, after he has inveighed against the crimes of Verres (lib. ii. c. 29.) breaks out into this pathetic exclamation: "O the clemency, or rather wonderful and singular patience of the Roman people?" The word *clemency* not being, in his apprehension, strong enough, he adds *patience*, as better answering his purpose. The sudden and unexpected turn of this figure gives a surprize to the mind, and by that means renders it the more pathetic.

EPANTHESMA, or EPANTHISMA, (from *επι*, and *ανθος*, a flower), in *Surgery*, an efflorescence; exanthema.

EPAPHÆRESIS, (from *επι*, importing a repetition, and *αφαιρησις*, a removal). In Galen it is employed in the sense of a repeated evacuation by bleeding.

EPARCHA, in the *Music of the Ancients*. Pollux, (Onomast. lib. iv. cap. 9.) tells us, that the eparcha was one of the strains of the Citharian mode, according to the division of Terpander. It was probably the prelude, for that is the signification of the word eparcha.

EPARCHUS, *Επαρχος*, an officer under the Greek emperors of Constantinople, who had the command of the guards, or government of a province.

EPARER, in the *Manege*, is used to signify the flinging of a horse, or his jerking or striking out with his hind legs: In caprioles, a horse must jerk out behind with all his force; but in ballottades he strikes but half out; and in croupades he does not strike out his hind legs at all. All horses that jerk are reckoned rude. See YERKING.

EPA'RGEMOS, (from *επι*, and *αργεμον*, signifying a white ulceration, or opacity of the eye), in *Surgery*, an epithet applied to a person affected with the disorder called argemon.

EPARITA, in the *Materia Medica*, a name given by Paracelsus to a sort of fine earth, of a liver colour, seemingly the same with the Tokay bole.

EPA'RMA, or EPA'RSIS, (from *επι*, and *αιρω*, to elevate,) in *Surgery*, a tumour of any sort. The term, however, is usually confined to a swelling of the parotid gland.

EPARRES, in *Geography*, a small town of France, in the department of the Îlère, near Vienne.

EPAULE, or ESPAULE, in *Fortification*, the shoulder of the bastion, or the angle made by the face and flank, otherwise called the angle of the epaule. See BASTION and ANGLE.

The word is pure French, and literally signifies *shoulder*.

EPAULE *en dedans*, in the *Manege*, a lesson of late invention, which, rendered into English, denotes that attitude in which, as the horse goes forward, he is so bent through his whole frame, that if he goes to the right hand, he must cross the right fore-leg over the left, and so *vice versa*; or, in the language of the Manege, his inner shoulder, or leg, over the outward. The old masters worked their horses upon circles, when they intended to supple the shoulders and haunches; but to this mode of working upon circles, it has lately been objected that it constrains the fore-part too much, and throws the horse upon his shoulders. To remedy this evil, M. de la Guerinierè, an accomplished horseman at Paris, invented the lesson called "epaule en dedans," and established it in his Manege. This new method, however, differs very little from the old practice, to which it owes its origin, and from which it is extracted and formed. The only objection against the circle is, that the horse, when worked circularly, has his haunches too much at liberty, by which means the weight of his body is thrown upon his

shoulders, which are thereby impeded in their motion; and the animal compelled to work in a manner directly opposite to what he should do. The blame, however, instead of being laid on the circle, should have been ascribed solely to the false and senseless manner in which horses were formerly worked in it; when heavy large bits and cavecons were used, with which the heads of horses were loaded, and brought down to a level with their knees, so that they carried them, like rams, when they fight, and batter one another with their foreheads. Had these old practitioners known the advantage, and, indeed, the necessity of raising the head, in order to press and bend the haunches, and of doing this by means of a snaffle with double reins, one being tied over the withers, on the opposite side to which the horse is to turn, the head would at once have been raised, the outward shoulder brought in, and the horse bent from nose to tail; but this discovery was reserved for sir Sidney Meadows, who has made many important improvements in the art of horsemanship. Berenger's Hist. &c. of Horsemanship. vol. ii.

EPAULEMENT. In treating of the enfilade, we had occasion to notice this part of the defences of batteries exposed to a flanking-fire. The designation is derived from the French word *epaule*, meaning "a shoulder," to which the epaulement bears a strong resemblance. Wherever a work, whether on the defences, or in the approaches of the besiegers, is subject to be enfiladed, and especially where that enfilade is *direct*, it becomes indispensibly necessary to raise an epaulement, for the purpose of warding off the shot. The thickness of such a buttress must always be proportioned to its height, which again must be carried up so far as may render the farthest gun, upon the battery to be secured, sufficiently safe from the ordinary *lobs* of shot fired en ricochet, as well as such as may enfilade by descent. A general rule may be easily formed; namely, that the epaulement should be full as thick as the parapet, be about ten feet, if practicable, beyond the prolonged line of the inner revetement of the terre-pleine, and be raised high enough to make an angle of ten degrees from the horizontal; the farther end of the battery being the angular point formed by the meeting of the terre-pleine, with a line drawn from the crest of the epaulement. If this proportion be properly attended to, it will be almost impossible to enfilade the defences with effect; because few ricochet shots, fired at an angle of ten degrees, will rise more than eight at their second flight. This mode gives a kind of standard, which proportions the height of the buttress to the length of the battery it is to protect.

Where there is space for such a work, it is often found highly advantageous to raise cavaliers at the extremities of the bastions, &c. which by their height serve as epaulements; but, as such defences, when they fall into the hands of the besiegers, not only afford a lodgment, but command the adjacent works, it is absolutely necessary they should be ruined; so that they may be completely annihilated whenever they are wrested from the defenders. It being a general rule, that the crest of the parapet should be full seven feet in height, very little elevation thereof will make a competent epaulement for a battery of small force, and especially where the cannon are placed as close up to the flank as circumstances may admit. This cannot be done so easily in salient angles which are acute, that is, under  $90^{\circ}$ ; but, in the flanked angles of bastions, &c. is generally very practicable. In the batteries and places of arms constructed by the besiegers, the epaulements may be made within ten feet of the outer cannon, and may be run up to any height, provided they do not obstruct the operations of other batteries; which, indeed, can be the case only in very peculiar situations.

situations. The best engineers recommend, that the epaulement should be merely temporary, except at the orillons on the extremities of the flanks of bastions, where they are always requisite to prevent such shots as may pass over the proximate bastion, when its angle or face may be battered, from enfilading the battery or the face of that bastion next to such orillon. When made on emergency, sand bags are found to answer admirably in the construction of epaulements; but when intended to be permanent, the buttresses should be made of the firmest soil, well compacted, and properly gazoned (*i. e.* turfed.) As we have remarked, while speaking of enfilades, no masonry should be exposed in the construction of epaulements any more than in traverses and parapets; on account of the incalculable mischief done by the numerous splinters which are knocked off by such shots as strike thereon.

**EPAULETTE**, is a distinguishing ornament, worn upon the shoulders of commissioned and of non-commissioned officers of some descriptions. The epaulette is always made to correspond in colour with the bindings and lace of the uniform: therefore where yellow binding is in use, gold embroidery, &c. are employed, and where white binding is adopted, silver embroidery only is suitable. The military service is by no means uniform in this ornament, some being epaulettes of one, some of another pattern; according to the fancies of the commandants respectively. The general rule is, that all general and field officers, as well as all superior staff officers, wear two epaulettes, the rest of the officers in a corps wearing but one. Though, as above stated, variety obtains, yet the generality consist of a rich strap, of gold or silver lace, cushioned below, to give it a square appearance upon the shoulder, and ornamented at its lower extremity with rich bullion, and fringe of a corresponding description; the upper end ordinarily fastens under, or on the cape, to a button; some being moveable, for the purpose of admitting a belt to pass underneath. The flank companies, *i. e.* the grenadiers and light infantry, generally wear wings, not altogether unlike crescents as they sit on the shoulder; of these the edges are ornamented with shorter bullions and fringe than are used in epaulettes. Some wings have shoulder-straps, others have none; and some are ribbed, or striped with narrow lace; but the generality are plain. In the navy, only large gold epaulettes are worn; all captains having two, and all under that rank but one. Formerly shoulder-knots, precisely resembling those in use among servants, were worn by many corps, especially the artillery. These originated in the use of chains, suspended from the collar down the arms, for the purpose of warding off the cuts of fabres; but they ultimately became merely decorative, and were from that period made of silver cords, plaited, looped, and tagged, which hung down generally in front of the shoulder. For the same purpose of defence, the cavalry have in some instances adopted a laminated epaulette, consisting of metal plates of various patterns, but commonly circular or oval, overlapping each other a little, so as to allow due play to the limb, yet forming no slight resistance against a fabre. It cannot be expected, that the shoulder should altogether escape injury, even though the edge of the weapon should be averted; since the ordinary force of an attempt to cut down the shoulder must prove extremely painful, and generally benumb the part for a while; or eventually cause a bruise of some consequence.

It is evident, from what we have detailed, that the epaulette may be considered as the type of a certain portion of armour, in use not many years ago; but which has become less necessary since discipline has empowered infantry to resist cavalry; and as the former laid aside their broad-swords in

déference to the adoption, and to the superiority of the musquet and bayonet.

Though, in some parts of the British service, the corporals still wear short shoulder-knots, and the serjeants retain their epaulettes, both being of cotton, worsted, or silk, the generality of them now wear the distinguishing marks of their respective ranks, in the form of fleches, or angular lacings on their sleeves. Some variation exists in this particular, according to the nature of their employ; but, in general, one, two, and three fleches are the ordinary indications of rank. Thus, where an order of merit is established among the privates, such as appertain thereto wear one fleche, the corporals having two, and the serjeants three. This mode does not, however, seem to carry so much notoriety with it as the epaulette, which can be seen both from before and from behind the individual wearing it; whereas the fleche can be distinguished but in one particular point of view.

**EPEE**, in *Geography*, a port of Africa, in the country of Benin.

**EPEMBOLE**, Επεμβολη, in *Rhetoric*, the same with parembolē.

**EPENCRANIS**, a name by which some of the old authors, particularly Erasistratus, have called the cerebellum.

**EPENDYTES**, Επειδυτες, among the Greeks, a garment worn under the pallium, and above the interula or inner coat, called, in Greek, ἑπειδυτης.

**EPENTHESIS**, formed of επι, εν, and τεθημι, *q. d.* επενθημι, *infero, immitto*, in *Grammar*, the addition, or insertion of a letter or syllable, in the middle of a word; as *relligio* for *religio*, *Mavors* for *Mars*, *alituum* for *alium*. Virg. *Æn.* lib. vii. ver. 27.

In the Hebrew language, there are some letters which are called *epenthetic*, and they occur without any apparent necessity in the middle of words; such are יןן. Masclaf's Heb. Gram. v. i. p. 191.

**EPERIES**, in *Geography*, a town of Hungary, celebrated for its mines of salt; 20 miles N. of Caschau.

**EPERLANUS**, in *Ichthyology*, a name sometimes given, on account of its pearl colour, to the smelt. See *SALMO Eperlanus*.

**EPERLEQUE**, in *Geography*, a town of France, in the department of the Straits of Calais; 2 leagues N.W. of St. Omer.

**EPERNAY**, or **ESPERNAY**, an ancient and handsome town of France, in the department of the Marne, chief place of the district of the same name, with a population of 4430 individuals. It is pleasantly situated on the river Marne, 21 miles N.W. of Châlons sur Marne, 18 miles S. of Rheims, and 88 miles E. by N. of Paris. N. lat. 49° 2'. The canton has a territorial extent of 110 kilometres, 11 communes, and 13,958 inhabitants.

As chief place of a district, Epernay has a sub-prefect, a ranger, a court of justice, and a register office. There are several manufactures of woollen stuffs, hosiery, cutlery, leather, and writing-paper; but the most remarkable is that of a sort of glazed earthen-ware, which stands the hottest fire.

The district of Epernay has 10 cantons, 215 communes, and 87,413 inhabitants, on a territorial extent of 2592½ kilometres. Its soil is uncommonly fertile, and produces corn, but especially that excellent red and white champaign of the very first quality, which is so much sought for all over the world. Epernay is the centre of the best champaign wines; its own vineyards and those of Ay produce the best; and the town has a great trade not only with

these, but also with the famous wines of the hills of Hautvilliers, Pierry, and Cumieres, which are not far distant.

EPERNON, a town of France, in the department of the Eure and Loire; 4 leagues N.E. of Chartres.

EPERON, in *Natural History*, the spur-shell, so called from its resembling, in some degree, the rowel of a spur. It is a species of snail, of the round-mouthed kind, or class of the cochleæ lunares; all its volutæ are surrounded with double rows of prickles. See LUNARIS *Cochlea*.

EPERONNIER, in *Ornithology*. See PAVO *Bicalcaratus*.

EPERUA, in *Botany*. See DIMORPHA.

EPERVIER. See FALCO.

EPERVIERS, in *Natural History*, a name given by the French authors to a class of butterflies, which make the sixth in Reaumur's method. They have a way of poizing themselves on the wing in the manner of kites, and other birds of prey; and always live upon the wing, never settling themselves upon the flowers they feed upon, but keep flying with a humming noise like a humble bee, while they thrust in their trunk and suck the juices of the flower.

EPETIUM, in *Ancient Geography*, a town of Illyria, on the coast of Dalmatia, between Salone and Pagentium, near the mouth of a river, now called Xarnouvra. The town which has succeeded to Epetium is named *Sirobez*.

EPHA, a dry measure in use among the Hebrews.

The epha was the most common measure they used, and that whereby the rest were regulated. It is commonly supposed that the epha, reduced to the Roman modius, contained four modii and a half. Now the Roman modius of grain or flour contained twenty libræ or pounds, consequently the epha weighed ninety pounds. Dr. Arbuthnot reduces the epha to three pecks three pints, English measure. See MEASURE.

EPHALGIA, in *Ancient Geography*, now *Elpisura*, a town of Asia, in Mesopotamia, upon the banks of the Euphrates, W.N.W. of Circesium.

EPHEBÆUM, Εφῆβαιον, in *Antiquity*, the place where the ephēbi or youth exercised; or, as some say, where those who designed to exercise met, and agreed what kind of exercise they should contend in, and what should be the victor's reward.

EPHEBI, Εφῆβοι, among the Athenians, a designation given to their young men when they arrived at eighteen years of age, at which time they had their names entered in a public register. Pott. *Archæol. Grec. lib. i. cap. 9. tom. i. p. 48.*

EPHEDRA, in *Botany*, (εφεδρα is an ancient name for a climbing or parasitical plant, and expresses a sitting upon any thing; hence it seems to allude to the squat or decumbent and crowded habit of this shrub.) Sea side Grape. Linn. Gen. 532. Schreb. 707. Willd. Sp. Pl. v. 4. 858. Mart. Mill. Dict. v. 2. Juss. 411. Class and order, *Dioscia Monadelphica*. Nat. Ord. *Conifera*.

Gen. Ch. Male, *Cal.* the scales of a catkin, few, single-flowered, roundish, concave, each the length of the perianth, which is of one leaf, cloven half way down, roundish, inflated, compressed, small and blunt. *Cor.* none. *Stam.* Filaments seven, united into an awl-shaped column, cloven at the top, and longer than the calyx; anthers roundish, turned outwards, four of them below the rest. Female, *Cal.* Perianth five-fold; one placed upon another so that their segments are alternate, forming an ovate figure; each is nearly ovate, of one leaf, cloven, the outer or lower ones smallest. *Cor.* none. *Pist.* Germens two, ovate, the size of the innermost perianth on which they stand; styles two, simple, thread-shaped; short; stigmas simple. *Peric.* none.

except the perianths, all become succulent and thickened; constituting a divided berry. *Seeds* two, ovate, acute, convex on one side and flat on the other, compressed by the perianth which incloses them on every side.

Ess. Ch. Male, Calyx the scale of a catkin, in two segments. Corolla none. Stamens seven. Anthers four inferior; three superior. Female, Calyx cloven, five-fold. Corolla none. Pistils two. Seeds two, inclosed in the pulp calyx.

The species known are but two.

1. *E. distachya*. Linn. Sp. Pl. 1472. Duhamel Arb. t. 92. (*Uva marina*; Ger. emac. 1116. f. 1, and 1117. f. 2.) "Flower-stalks opposite. Catkins in pairs." Native of various parts of the south of Europe, in a sandy soil about the shores of the sea or of lakes, flowering in June and July. It bears our climate, especially if led upright against a wall. A fine bush of this kind may be seen in the Oxford garden, ten or twelve feet high. It is a bushy, smooth, leafless shrub, always green, with the habit of an *Equisetum*. The catkins are yellowish. *Berries* scarlet, sweetish, viscid, eatable but not agreeable.

2. *E. monostachya*. Linn. Sp. Pl. 1472. (*E. polygonoides*; Pall. Ross. v. 1. t. 83.) "Flower-stalks several. Catkins solitary." Native of Siberia. Linnæus suspected this to be only a variety of the last, and Pallas confirms his opinion.

EPHELÆUM, in *Anatomy*, is the place from the hypogastrium, or lower part of the abdomen, to the secret parts.

EPHELICIS, from επι, and ἔλκος, an ulcer, in *Surgery*, a scab, or crust, upon a sore.—Also, a small portion of blood, voided by coughing.

EPHELIS, from επι and ἥλιος, sun, a name used by the ancient writers on *Medicine*, for a disorder of the face, brought on by the sun and drying winds, and of the nature of what we call sun-burning. It was a certain roughness, hardness, and bad colour of the skin.

The ephelis, or sun-burning, is removed by an application of resin, to which a third part of fossil salt, and a little honey are added; but all these disorders, as also the unnatural colour of cicatrices, are remedied by the following preparation, ascribed to Trypho the Elder:

Take equal quantities of myrobolans, crocomagna, cimolian earth of a blueish colour, bitter almonds, the meals of barley and bitter vetch, dyer's weed (*Struthium album*); all these are to be triturated together, and made up with the most sharp honey. With this preparation the parts affected are to be anointed at night; and the medicine carefully to be washed off the next morning. James Med. Dict. See FRECKLES.

EPHEMERA, from ἐπι and ἡμερα, a day, in *Medicine*, the name given by the Greek writers to the mildest form of fever, which runs through its course within the period of one day. By the Romans the same fever was termed *diaria*, from *dies*, a day.

A fever which terminates in the course of twelve, eighteen, or twenty-four hours, is not a common occurrence in this climate; unless the slight disturbance of the system, which fatigue, repletion, a sleepless night, &c. induce, is to be called an ephemeral fever: and such, indeed, appears to be the disorder to which the term *ephemera* has been applied by writers in general, and which constitutes the *ephemera simplex*, or *legitima*, in their nomenclature. When the febrile condition is more severe, and therefore of longer duration, extending to the third or fourth day, by a solecism in language, it has been denominated *ephemera extensa*, or *ephemera plurimum dierum*. Any slight fever, of three

## EPHEMERA.

or four days duration, is occasionally called an ephemerata at present; the slight derangement of the habit, from the operation of the causes just mentioned, being scarcely deemed a disease worthy of a distinct appellation.

The ephemerata simplex is a slight febrile paroxysm, marked by languor, loss of appetite, thirst, headache, and slight pains in the limbs, with some heat of skin terminating in a gentle perspiration, and with dryness of the tongue and fauces. These symptoms, from their mildness, imply a very slight derangement of any of the functions of the body: they originate from some evident cause of disorder in what have been absurdly termed the non-naturals, and cease spontaneously when the influence of these causes no longer operates. The mildness of the symptoms, and the nature of the evident causes, are mentioned as the principal means of discriminating the ephemerata from the various forms of continued fever at their commencement. Among the causes of the ephemerata are enumerated the various passions of the mind, when strongly excited, as grief, anger, joy, or care and anxiety, likewise loss of sleep, excessive heat of the weather, fatigue from labour or exercise, a fit of intoxication or of repletion, sudden exposure to cold, fasting, too great evacuations, &c. It is admitted, indeed, that many of these causes occasionally give rise to continued fevers of long duration; but, in these cases, the attack is preceded by cold chills and shiverings, by languor and lassitude, loathing of food, &c. and is accompanied by more severe disorders of the functions, as by violent headache, pains in the back and limbs, nausea or vomiting, with great anxiety and restlessness. The presence or absence of these symptoms, in the commencement, will enable us to anticipate the future progress of the disease, whether it will be a mere ephemerata or a more serious continued fever.

Besides the simple ephemerata, arising from the causes already enumerated, which Sauvages has included under the four heads of ephemerata plethorica, ephemerata nauseativa, ephemerata à frigore, and ephemerata à calore, those slight febrile derangements, connected with bruises, dislocations, parturition, congestion of milk in the breasts, dysmenorrhœa, &c. have been also designated by the term ephemerata; which, in this case, is a secondary or symptomatic ephemerata. Avicenna, among the ancients, and Forestus, among the modern physicians, have made a still more extensive division of ephemerata; namely, into as many species as there are evident causes which induce it. Hence they uselessly distinguish ephemerata from grief, from joy, from hope, from fear, from thirst, from fasting, &c.

The original signification of the term implied a completion of all the stages of a fever, *viz.* the beginning, increase, acmè, and decline, (in the language of the ancients,) within the compass of a natural day. By this definition, Van Swieten observes, the most acute fevers, which often kill a patient in twenty-four hours, are excluded from the term; since they do not arrive at their declension in that space of time, although they end in death. Yet Caius has described that fatal epidemic, the *sweating sickness*, or *sudor Anglicus*, under the term of ephemerata; because, on the one hand, it often terminated in the space of twenty-four hours, by destroying the patient; and, on the other, by a sweating, continued for the same space of time, the patients were often cured. But in this case, though immediate danger was removed, yet great debility and other injuries to the functions still remained, for some time afterwards; so that the disease belonged to the class of continued malignant fevers. This disease, under the appellation of ephemerata sudatoria, constitutes the seventh species of Sauvages. It has been also denominated ephemerata Bri-

tannica, ephemerata maligna, ephemerata Anglica pestilens, &c. See SWEATING *Sickness*.

With respect to the cure of the ephemerata fever, little remains to be said. The term implies that its natural termination will occur within the period of a day, if left to itself: we here speak of the simple ephemerata, arising from a slight temporary cause. Abstinence alone, or the most light and slender diet, with diluent drinks, is all that is required. The bowels may be opened by gentle aperients, as neutral salts, infusion of fenna, &c.: and this ought not to be omitted, where the disease has arisen from over-repletion, or intoxication; in which case, it will contribute directly to remove the exciting cause of the disorder. Thin drinks, such as spring-water, or barley-water, acidulated or not with the juice of lemons, tea, or the infusions of other grateful herbs, may be used, and animal food abstained from.

The same treatment will be useful in the secondary or symptomatic forms of ephemerata; in which cases, however, the cure or alleviation of the original disorder must be the first step towards removing the ephemerata. See Galen Method. Medend. lib. viii. De Febris, lib. i. &c. Van Swieten, Comment. App. 728. Burferius Instit. Med. tom. i. sect. 198. Sauvages Nos. Meth. class. ii. genus 1.

EPHEMERA, in *Entomology*, a genus of the neuroptera order. This genus has the mouth destitute of mandibles; feelers four, very short, and filiform; jaws short, membranaceous, cylindrical, and connected to the lip; antennæ short and subulate; stemmata too large above the eyes; wings erect; the lower smaller; tail terminating in bristles.

The ephemeræ are proverbially a race of beings destined to enjoy the functions of life for a much shorter period than any other animals. This is a popular opinion, and, in a partial view of their history, not altogether incorrect; but it must be understood only of the last or winged state, after attaining which they exist but for a few hours. The duration of this period varies in different species. It is devoted solely to the pleasures of fulfilling the ordinary purpose of nature, the propagation of their kind; in the accomplishment of which the ephemeræ may be observed in myriads, during the summer season, sporting on the wing, just above the surface of the water. In the larva and pupa states the ephemeræ live one or two years; and some species, it is believed, live even three years from the time of hatching from the egg state, before they arrive at the perfect form. The larvæ are found in the water, wherein they constantly reside, and are the favourite food of fishes. They are active, furnished with six legs, a tail, six lateral fins or gills, and prey on smaller insects. The pupæ, like the larvæ, are carnivorous, and resemble the former state, except in having the rudiments of the wings apparent. The ephemeræ are so abundant in some countries, that they are used for the purpose of manure, the species vulgata especially. This is the common practice with the husbandmen in Carniola. They are also very numerous on some parts of the Rhine, the Maes, and Ifel. The season of their appearance in such multitudes continues, however, only for about three days annually. The ephemeræ are arranged in two sections, according to the number of bristles at the extremity of the tail.

### Species.

\* Tail with three hairs or bristles.

VULGATA. Wings reticulated, and spotted with brown; body yellowish, spotted with black. Scop. Donov. Brit. Ins., &c.

Inhabitants

Inhabits watery places throughout Europe.

**LUTEA.** Wings transparent, reticulated; body yellow. Fabr.

Native of Europe, and is found in Britain.

**MARGINATA.** Wings white; exterior margin fuscous; body black. Fabr.

Similar to *E. vulgata*, but smaller.

**VESPERTINA.** Wings black; posterior ones white. Linn.

Native of Sweden, and other parts of Europe.

**HALTERATA.** Wings two, white; abdomen whitish, with fuscous tail. Fabr. *Phryganca cauda trifida*, &c. Degeer.

Inhabits stagnant waters in the north of Europe.

**INANIS.** Wings hyaline; body black; segments of the abdomen from the fourth to the seventh pellucid. Linn.

Native of Europe.

**MAROCCANA.** Wings white, immaculate; body yellowish. Fabr.

Found in Morocco.

**BREVICAUDA.** Wings two, cinereous, with a black rib; abdomen pale; tail brown. Fabr.

A small species, found in the vicinity of Paris.

\*\* Tail with two hairs or bristles.

**BIOCULATA.** Wings white reticulated; head with two yellow tubercles; tail yellow. Fabr. Geoff., &c.

Native of European waters.

**RENSA.** Wings white reticulated; body brown. Fabr. Inhabits Denmark.

**NIGRA.** Body black; wings blackish; posterior pair very small. Linn.

Described by Linnæus as a native of Sweden; also inhabits other parts of Europe.

**CULICIFORMIS.** Wings white; body brown. Linn.

Found in Greece by Pada; also in Sweden by Linnæus, and in France by Geoffroy.

**HORARIA.** Wings white; thicker-margin blackish. Linn. *Ephemera minima*, Swammerdam.

Very abundant in Europe.

**STRIATA.** Wings hyaline, striated; thorax fuscous; abdomen white. Fabr. *Ephemera mutica*, Linn. Fn. Suec.

An European species.

**DIPTERA.** Wings two; costal margin brown, with cinereous spots. Linn.

The abdomen in this insect is marked with red lines. The species inhabits Sweden.

**FUSCATA.** Wings hyaline; abdomen brown, with the base whitish; legs pale. Fabr.

**ALBIPENNIS.** Wings white, immaculate; abdomen pale at the base; tail blackish. Fabr.

This and the preceding inhabit France, and other parts of Europe.

**NOTATA.** Yellow; wings white; abdominal segments with a fuscous spot each side. Linn.

*Ephemera notata* and the three following are inhabitants of watery places in Europe.

**TESTACEA.** Wings brownish; body brown testaceous; soles of the feet fuscous. Linn.

**FERRUGINEA.** Wings yellowish; body ferruginous. Linn.

**STIGMA.** Wings brownish; body pale yellow; thighs with a black dot in the middle.

**EPHEMERA**, is also applied among *Botanists*, to a kind of flowers which open and expand themselves at sunrise, and wither or close up again at his setting. Such are the dent-de-lion, vulgarly dandelion, and divers others.

**EPHEMERIDES**, in *Astronomy*, tables calculated by astronomers, shewing the present state of the heavens for every day at noon; that is, the places wherein all the planets are found at that time.

It is from these tables that the eclipses, conjunctions, and aspects of the planets are determined; horoscopes, or celestial schemes, constructed, &c.

We have ephemerides of Regiomontanus from 1475 to 1506, of Engel from 1494 to 1500, of Staefler from 1499 to 1531, of Origan from 1595 to 1654, of Kepler from 1617 to 1628, of Argoli from 1620 to 1700, of Heckerus from 1666 to 1680, of Wing from 1652 to 1671, of De la Hire from 1701 to 1703, of Manfredi from 1715 to 1750, of Parker, &c. S. Cassini has calculated ephemerides of the sidera medicæ, or satellites of Jupiter, which are of good use in determining the longitude.

In England the Nautical Almanac or Astronomical Ephemeris, published annually by anticipation, under the direction of the Commissioners of Longitude, is the most considerable. See **ALMANAC**.

In France they have preserved in the national library ephemerides of 1442; and celestial ephemerides have been published by M. Desplaces every ten years, from 1715 to 1745: they were afterwards continued by the abbé Caille, with many additions, from 1731 to 1774, of which an account may be seen in the History of the Academy of Sciences for 1743, &c.; they were further continued by Lalande from 1775 to 1810. The Academy of Sciences have likewise published annually, from the year 1678, a kind of ephemeris, under the title of *Connoissance des Temps*. This has been continued since the revolution under the direction of the "Bureau des Longitudes." The two volumes for the years 8 and 9, edited under the inspection of M. Lalande, contain, besides other important articles, new catalogues of the stars; tables of the moon's horary motion by Delambre; observations of Mercury by Vidal, &c. They have also ephemerides at Bologna; those for 23 years from 1787 to 1810, being computed by C. Mateucci, assisted by Molani, Guglielmini, Sacchetti, Zanotti, and Canterzani. The ephemerides of Milan contain the result of an important labour of C. Oriani, on the method of correcting the elements of the tables of Mercury by observation, and many interesting observations of C. Reggio and De Cesaris, &c. &c. The ephemerides of Berlin are now conducted by M. Bode, and contain many astronomical observations and memoirs by German, French, and English astronomers. The astronomers of Vienna commenced a similar work in 1757. The geographical ephemerides, undertaken by M. Von Zach, of Gotha, at the commencement of the year 1798, contain many curious observations; information respecting new books and charts, new voyages and geographical maps, portraits of eminent philosophers, and, in a word, every thing that can be interesting to astronomers, geographers, and navigators. The meteorological observations of the electoral Academy of Sciences at Manheim, from 1781 to 1792, are comprehended in 12 volumes 4to. under the title of "*Ephemerides Societatis Meteorologicæ Palatinæ*."

**EPHEMERUM**, in *Botany*, from *επιμερος*, lasting but a day, in allusion to its transient blossoms; see **LYSIMACHIA**. The name has also been given in ancient times to the hemlock, on account of the celerity of its destructive action upon animal life.

**EPHESIA**, in *Mythology*, a feast instituted at Ephesus, in honour of Diana.

**EPHESIANS**, **EPISTLE** to. See **EPISTLE**.

**EPHESIORUM PORTUS**, in *Ancient Geography*, a port

port of Asia Minor, upon the Bosphorus of Thrace; the modern name of which is *Aphestiati*.

EPHESIUM, the name of a plaster, which is described by Celsus.

EPHESIUS, in *Biblical History*, a manuscript of the gospels written in 1166, and formerly in possession of a bishop of Ephesus, whence it has taken its name. It is noted 71 in the first part of Wetstein's N. T. It is at present in the archbishop's library at Lambeth, to which it was presented by Trahern, together with the extracts which he had made from it. These were inserted by Mill, in his collections of readings.

EPHESTIA, in *Mythology*, a feast celebrated in honour of Vulcan, in which three young lads ran for a prize.

EPHESTRIA, were feasts celebrated at Thebes, in honour of Tyresias.

EPHESUS, in *Ancient Geography*, a city of Asia Minor, in Ionia, formerly reputed the metropolis of Asia. Stephanus styles it "Epiphaneſtata," or most illustrious. Pliny represents it as the ornament of Asia; and Strabo describes it as the largest and most frequented emporium of that continent. The ancient city, which was originally a small village, stood about 50 miles S. of Smyrna, near the mouth of the river Cayster, and the shore of the Icarian sea, which is a bay of the Ægean; but its precise situation cannot be ascertained, as it was often destroyed and rebuilt. Some modern travellers maintain that the ancient city stood more to the south than the present town, or rather village, which they infer from the ruins that still remain. It was known in ancient times by the names of Alopes, Ortygia, Morges, Smyrna, Trachæa, Samornion, and Ptela. Its name Ephesus is derived, according to Heraclides, from the Greek word *ephefus*, signifying permission; because Hercules, as he says, permitted the Amazons to live and build a city in that place. Others allege, that Ephesus was the name of the Amazon that founded the city: for Pliny, Justin, and Orosius unanimously affirm, that it was built by an Amazon; while others ascribe the honour to Androclus, the son of Codrus, king of Athens, who was the chief of the Ionians that settled in Asia. However this be, it is acknowledged, that the city, which in the Roman times was the metropolis of Asia, was founded by Lyſimachus; who, having caused the ancient city to be demolished, rebuilt a new one, at a vast expence, in a place more convenient, and nearer the temple. We learn from Strabo, that when the inhabitants manifested a reluctance to quit their ancient habitations, this prince caused all the drains, that conveyed the water into the neighbouring fens and the Cayster, to be privately stopped up: so that the city on the first violent rains that fell was in great part laid under water, and many of the inhabitants were drowned: and he thus constrained those who remained to retire into the new city. This new Ephesus was greatly damaged by an earthquake in the reign of Tiberius, but that emperor repaired and adorned it with several stately buildings, of which there are now some few ruins that testify its existence. The aqueduct, of which a part still subsists, is generally believed to have been the work of the Greek emperors; the pillars, that support the arches, are of fine marble, and they are higher or lower as the level of the water required. This aqueduct served to convey water into the city from the spring of Halitæe, mentioned by Pausanias. The gate, now called for some unknown reason the gate of persecution, is remarkable for three bas-reliefs on the mould, of exquisite taste. The port, of which many medals have been struck, is at present merely an open road, and not much frequented. The Cayster was formerly navigable, and afforded a safe place for

ships to ride in, but it is now almost choaked with sand. Ephesus is now venerable for nothing but the ruins of palaces, temples, and amphitheatres. It is called by the Turks *Ajafaluk* (which see), or the temple of the moon, from the magnificent structure formerly dedicated to Diana. The church of St. Paul, said to have been founded by the apostle, is wholly destroyed; the little which remains of that of St. Mark is sinking to ruin. The only church remaining is that dedicated to St. John, who resided here, and this is now converted into a Turkish mosque. The town is merely a miserable village, the habitation of herdsmen and farmers, living in low and mean huts, sheltered from the extremities of weather by mighty masses of ruinous walls; the pride and ostentation of former days, and the emblem in these of the transient vanity of human glory. All the inhabitants of this once famous city amount not to above 40 or 50 families of Turks, without one Christian family among them; so strikingly hath the scripture denunciation been fulfilled, that "their candlestick should be removed out of its place."

The ancient city, whether it was first built by Androclus, who conducted the Ionians hither and drove out the Carians and Leleges, by whom this situation was occupied before his arrival, or by one Cræſus or Ephesus, long before the Ionic migration, as others maintain, became soon the metropolis of Ionia. It was at first governed by Androclus and his descendants, who assumed the royal title, and exercised regal authority over the new colony; whence, even in Strabo's time, the posterity of Androclus were styled kings, and allowed to wear a scarlet robe, with a sceptre, and all the ensigns of royal dignity. In process of time, a senate was established and a new form of government introduced, which continued to the time of Pythagoras, who lived before Cyrus the Great, and was one of the most savage tyrants whose name and character history records; for having expelled the senate and engrossed the whole power, he filled the city with blood and rapine, not sparing even those who fled for shelter to Diana's temple. His successor Pindarus governed the city with a milder sway; and in his time Ephesus was besieged by Cræſus, king of Lydia, who advised the inhabitants to devote their city to Diana, and in consequence of their following his counsel, treated them with kindness, and restored them to their former liberty. The other tyrants of Ephesus, mentioned in history, are Athenagoras, Comes, Aristarchus, and Hegesias; the last of whom was expelled by Alexander, who, having defeated the Persians on the banks of the Granicus, bestowed upon Diana all the tributes which the Ephesians had paid to the Persians, and established a democracy in the city. After his death, this city became the prey of his successors. Lyſimachus took it, and afterwards Antigonus had possession of it and plundered it. Ephesus for a little while was restored to its ancient splendour; but it was always subject to the kings of Syria. In the war between Mithridates and the Romans, the Ephesians took part with the former, and by his order massacred all the Romans that resided in the city; for which barbarity they were severely fined, and reduced almost to beggary by Sylla, but afterwards treated kindly and suffered to live according to their own laws. It was under the reign of the emperor Alexius, father of Anne de Comnena, that the Mahometans made themselves masters of Ephesus. The Greeks retook it in 1206, but they lost it again 1283. At the commencement of the 14th century it became a part of the Turkish dominions; and both the place itself and its vicinity exhibit melancholy traces of indolence and inactivity. The Ephesians were much addicted to superstition, forcery, and curious arts, as the Scripture styles them (*Acts, xix. 19.*); whence came the proverb

proverb "Ephesian letters," signifying all sorts of spells or charms. By these Ephesian letters were meant certain obscure words and incoherent sentences, which superstitious bigots used to write on their girdles, and even imprint on their feet, and other parts of their bodies. They were also noted for their luxury and lasciviousness. See Ephes. v. 5.

Ephesus, in its relation to ecclesiastical history, may be considered, first of all, as the abode of many Jews, who obtained the privilege of citizens (Joseph. Cont. Appian. l. 2.), and afterwards, as the place where St. Paul took up his residence for three years (Acts, xx. 31.), where he wrought miracles (Acts, xix. 11. 1 Cor. xvi. 9.), and was resisted by the Jews, (Acts, xx. 19.); and where Timothy was bishop; and where John resided; and, moreover, as containing one of the seven churches, whose character and doom are recorded in the book of Revelations, ch. ii.

EPHESUS, *Temple of*. See DIANA.

EPHETÆ, of ἐφημι, *I send forth*, in *Antiquity*, a sort of magistrates among the Athenians, instituted by king Demophoon, to take cognizance of murder, manslaughter, and chance-medley.

Their number was one hundred, whereof fifty were Athenians, and fifty Argians: they were not admitted to the post till upwards of fifty years of age. Demophoon submitted to be tried by this court, for having unfortunately killed one of his subjects by the turn of his horse, as he was coming from Troy. It subsisted for a considerable time in the same form; but at length Draco new-modelled it, excluded the Argians, and made it to consist of fifty-one Athenians, each above fifty years of age: Ubbo Emmius de Rep. Athen. says, he transferred to them part of the jurisdiction of the Areopagites. See AREOPAGUS.

The occasion of erecting this court and of admitting the Argives to sit as judges, is said to have been as follows. Agamemnon, or, as others say, Diomedes, returning with his forces from Troy, were driven one night into an Athenian port called Phalerus, and thinking themselves in an enemy's country, began their usual practice of ravaging and plundering; upon which the Athenians fell upon and killed a considerable number of them. Next morning they found the palladium, or statue of Minerva, which was brought from Troy, lying upon the ground among the slain; by which circumstance they knew that they were their friends the Argives. The oracle having been consulted, ordered them to give the slain an honourable burial in the place where they fell, to build a temple there, dedicated to Minerva, and to set up the palladium in it. Immediately after this transaction, it was ordered that this court should be erected to try all cases of personal injury and property. It consisted of 50 members, who were to be above 50 years of age, men of sense and known probity, and who had power of life and death. Upon its first institution Agamemnon insinuating that there should be an equal number of Athenians and Argives, the Athenians readily agreed to the proposal.

EPHIALTES, ἐφιάλτης, in *Medicine*, from ἐπι, upon, and αλλομαι, *I leap*, is synonymous with the Latin *incubus*, and the English *night-mare*, which see.

EPHIALTEUM, in *Ancient Geography*, the most northern promontory of the isle of Rhodes.

EPHIDROSIS, in *Medicine*, from ἴπρι, and ἰδρῶς, *sweat*, a term used by the ancient writers to denote the appearance of a sweat, whether critical or not, and whether general, or on the upper parts of the body only. The modern nosologists have constituted a *genus* of disease under this appellation; under which Sauvages comprises every variety of morbid perspiration that occurs as a symptom of

different maladies. He enumerates seventeen species of ephidrosis. See his Nosol. Method, Class IX. Gen. 20. Cullen, Gen. 118.

EPHIELIS, in *Botany*, from ἐφιάλις, a little cup, or something like it, in a crown or garland, which alludes, happily enough, to the nectary forming a sort of cup, or crown, within the circle of the corolla. Schreb. 253. Willd. Sp. Pl. v. 2. 328. (Mataiba; Aubl. Guian. v. 1. t. 128. Juss. 249.) Class and order, *Oelandria Monogynia*. Nat. Ord. Near the *Sapindi*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, in five deep, spreading, roundish, acute segments. *Cor.* Petals five, roundish, spreading, notched, with a small point, and having claws as long as the calyx. Nectary of ten roundish hairy scales, smaller than the petals, two of them affixed to the base of each petal. *Stam.* Filaments eight, bristle-shaped, longer than the corolla, inserted into a gland; anthers roundish, with four angles. *Pist.* Germen ovate, encompassed with the gland which bears the stamens; style none; stigma obtuse. *Peric.* Capsule oblong, compressed, with a furrow on each side, of one cell and two valves. *Seeds* two, kidney-shaped, one attached to the middle of each valve, one above the other.

Eff. Ch. Calyx in five deep segments. Petals five, with claws. Nectary of ten scales, two to each petal. Capsule compressed, of one cell and two valves. Seeds two, attached to the valves.

The only known species is *E. fraxinea*, Willd. a tree 50 or 60 feet high, with copious branches, of which the central ones are erect, the rest widely spreading. Leaves alternate, pinnate, smooth; leaflets four or six, opposite, oval, pointed, entire, bright green, sometimes eight inches long. Flowers on long axillary branching stalks, very small, white. It grows in the forests of Guiana, flowering in October. Jussieu suspects this genus may be more akin to the *Leguminosæ* than to his *Sapindi*, but he observes that the fruit requires further investigation.

EPHIPPIA, of ἐπι and ἵππος, *horse*, denoted certain cloths or housings, which were fastened on a horse by a girth or surcingle, in ancient Greece, before the use of saddles were known. They were composed of different materials, as leather, cloth, and the skins of wild beasts, and sometimes adorned with gold, silver, and precious stones. When these coverings were common, it was reckoned more manly to ride without them. Varro boasts of having rode, when a young man, without a covering to his horse; and Xenophon reproaches the Persians because they placed more clothes on the backs of their horses than on their beds, and gave themselves more trouble to sit easily than to ride skilfully. These coverings were, therefore, for a long time not used in war; and the old Germans, who considered them as disgraceful, despised the Roman cavalry who employed them. (Cæs. de Bell. Gall. l. iv. 2.) Dion Cassius (l. lxxiii. 14.) says, that they were first allowed to the Roman cavalry by Nero. But it has been suggested that this author alludes merely to reviews, at which the cavalry were probably obliged before this time to appear always without them. In the time of Alexander Severus, the horses of the whole Roman cavalry had beautiful coverings. (Lamprid. Vit. Alex. Severi. c. 50.) Saddles were first denominated ephippia, which originally signified nothing more than a covering for a horse. Beckmann Hist. Inv. vol. ii. Berenger's Art of Horsemanship, vol. i. p. 41. See SADDLE.

EPHIPPIITES. See HIPPIURITES.

EPHIPPIUM, in *Anatomy*, the excavation in the upper surface of the sphenoid bone, called also sella turcica. See CRANIUM.

EPHOD, אֶפְדֹּד, derived from אָפַד, *aphád*, to clothe, a sacerdotal garment, in use among the ancient Jews, supposed to have been a kind of linen alb, or surplice, wore by persons of distinction, of various characters; the same with what the Latins call super-humerales. 2 Sam. vi. 4. 1 Sam. xxii. 18. 1 Sam. ii. 18.

It is very hard to say precisely what the ephod was; and there is room enough for the interpreters to be divided about it. The only point they are agreed upon is, that it was an upper garment worn over all the rest, immediately under the pectoral or breast-plate. Some hold it had sleeves, others deny it. The generality agree, that it was very short, though some maintain that it hung down to the feet behind.

There were two kinds of ephods; the one, common to all who assisted in the temple, being only made of common linen, mentioned in the first book of Samuel, ii. 18; the other, peculiar to the high-priest, mentioned Exod. xxviii. 6. 15. to be made of gold, of blue, and of purple, of scarlet, and fine twined linen, with cunning work; having two shoulder-pieces, with a curious girdle of the same matter, and two onyxes, with the names of the children of Israel engraved thereon, six upon each stone. These onyxes were set in gold, and served as buttons upon each shoulder. As for the shape of the ephod, the LXX call it *επιμυς*, which signifies that it was worn on the shoulders.

Josephus says (Antiq. l. iii. § 5), that it was a cubit long. It consisted, as some suppose, of two parts, the one an oblong rectangular piece, hanging down behind from the shoulders to the feet; the other a short rectangular piece, which hung down before, the length of a cubit. These two pieces were joined together upon the shoulders, with some proper fastening, as loops, buttons, or the like.

It is also expressed in the second book of Samuel, vi. 14. that upon the removal of the ark of the covenant from the house of Obed-Edom, David danced for joy, girt with a linen ephod; whence some authors have concluded, that the ephod was also a regal garment, worn on solemn occasions. It is probable that the peculiarity of the ephod of the high priest did not consist in its being of a different shape from that which was worn by other persons; but in the richness of the materials of which it was made, and the fine embroidery and jewels with which it was adorned.

EPHORI, Εφοροι, magistrates established in ancient Sparta, to balance and check the power and authority of the kings; as at Rome, there were tribunes created to controul the power of the consuls.

The word is formed of the Greek, *εφορα*, *intueor*, formed of the preposition *επι*, and the verb *οραω*, to see; whence *εφορος*, *q. d. inspector, overseer*.

Lycurgus, being sensible that a perfect understanding between the prince and the people was the basis and foundation of both their happiness, to maintain that good understanding, established ephori, or inspectors, as a kind of mediators, who should have an eye to the measures and conduct on both sides, and preserve so equal a balance between them, that the regal power should never decline into severity and tyranny, or the liberty of the people run into licentiousness and rebellion.

This is the account of their institution given by Herodotus and Xenophon. (Her. lib. i. Xen. de Rep. Lacedæm.) The authority of the ephori was very great; they presided in popular assemblies, collected their suffrages, declared war, made peace, treated with foreign princes, determined the number of forces that should be raised, appointed the funds to maintain them, and distributed rewards and punishments in the name of the state; they likewise held a court of jus-

tice, enquired into the behaviour of all magistrates, inspected the education and conduct of youth, had a particular jurisdiction over the helotes, and by degrees drew the whole administration into their own hands. On certain occasions, they expelled, and even put to death the kings; and abolished or suspended the power of the other magistrates, calling them to account at pleasure. Agesilaus, in the height of all his conquests, which even struck terror on the great king of Persia, stopped, and turned back, out of deference to the ephori, when they recalled him.

Some authors deny that the ephori were established by Lycurgus, dating their origin 130 years after the time of that legislator.

Thus Plutarch, in his life of Cleomenes, ascribes their institution to Theopompus, king of Sparta, which is also confirmed by the authority of Aristotle. (Polit. lib. v.) The ephori were five in number, and annually chosen by the people out of their own body: though some have imagined, that they were at first appointed by the kings at their pleasure, but that afterwards the people obtained the power of electing them. The year was denominated from the first election of these magistrates; and the Lacedæmonian armies took their names from the principal ephori, as those of Athens did from their first archon. The ephori did not rise up at the entrance of the kings, as all the other magistrates did; and if even the kings offended against the laws, the ephori took cognizance of their conduct, and punished them.

EPHORUS, in *Biography*, a Greek orator and historian, was a native of Cuma or Cyme in Æolia, and flourished about the year 352 B. C. He was a disciple of Socrates, at whose instigation he wrote history; which he commenced after the fabulous periods, with the return of the Heraclidæ into Peloponnesus, and brought down to the 20th year of Philip of Macedon. This work, which was divided into 30 books, was held in estimation by the ancients, and is frequently cited by Strabo and other writers; though the historian is charged with errors and misrepresentations, and plagiarisms. Besides the history, the loss of which is regretted, Ephorus wrote several other books on moral, geographical, and rhetorical subjects, none of which are extant, Bayle. Voss. Hist. Græc. Gen. Biog.

EPHRA, in *Ancient Geography*, a city of Judea, in the half-tribe of Manasseh, on this side of Jordan. It was situated on the frontiers of the tribe of Ephraim; supposed to have been the same with Ophrah. Judg. vi. 11.

EPHRAIM, *Tribe of*, so denominated from Ephraim, the grandson of Joseph by Aseneth, the daughter of Potiphar, who was born in Egypt about A. M. 2294, occupied the south side of Samaria, and extended, like that of Manasseh, from the Mediterranean on the west, and the river Jordan on the east; bounded on the south by the territory of Benjamin and part of Dan, and on the north by the half-tribe of Manasseh. The extent of this tribe from north to south was about 7 leagues; and though some parts were mountainous and rocky, they were covered with trees and good pasture, and the low lands were rich and fertile, and even luxuriant. The cities and towns were numerous, large, and well-peopled. Joshua was of this tribe; and the ark and tabernacle remained in it at Shiloh for a considerable time. After the separation of the 10 tribes, the seat of the kingdom of Israel being in Ephraim, Ephraim is frequently used to signify the whole kingdom. The district belonging to this tribe is called Ephratah. Ps. cxxxii. 6. (See also Judg. xii. 5. 1 Sam. i. 1.) Ephraim was led captive beyond the Euphrates, with all Israel, by Salmaneser, king of Assyria, A. M. 3283. B. C. 721.

EPHRAIM, or *Ephraim*, a city of Ephraim, towards Jordan, whither Jesus is supposed to have retired before his passion. John, xi. 54.—Also, a city of Benjamin, 8 miles from Jerusalem, according to Eusebius, near the wilderness of Judea, in the way from Jerusalem to Jericho, not far from Bethel.—Also, a considerable mountain in the tribe of Ephraim, and extending to that of Benjamin, on which several towns were built.—Also, an extensive forest situated on the other side of Jordan, not far from Mahanaim, where David abode while the battle was fought, in which Abalom received the due reward of his unnatural rebellion.

EPHRATA, or *DUNKARD-Town*, in *Geography*, a village of America, in Lancaster county, Pennsylvania, on the N.W. side of Calico creek, which, joining the Conestoga, falls into the Susquehanna; 12 miles N. of the town of Lancaster, and more than 40 W. of Philadelphia. It is situated in a romantic and sequestered vale, and inhabited by a community of religious people, called "Tunkers," who are mostly of German descent and believers in the doctrine of general redemption. They are very plain in their dress and language; and will neither swear, nor fight, nor go to law, nor take interest for the money they lend. They have many peculiarities; but their inoffensive manners have occasioned their being called the harmless Tunkers. This settlement is called "Tunkers' town," and consists of about 40 buildings, of which three are places of worship. They subsist by cultivating their lands, by attending a printing office, a grist-mill, a paper-mill, an oil-mill, &c. and the sisters by spinning, weaving, sewing, &c. Beside this congregation at Ephrata, there were, about 30 years ago, some few others of this sect in various parts of Pennsylvania, and in Maryland. The whole community, exclusively of those in Maryland, comprehended upwards of 2000 persons.

EPHRATAH. See *Tribe of EPHRAIM* and *BETHLEHEM*.

EPHREM, or *EPHRAIM*, denominated the *Syrian*, and honoured with the appellation of *Saint*, in *Biography*, was a native of Nisibis in Mesopotamia, and born during the reign of Constantine the Great. Devoting himself at an early period to the monastic life, he sedulously applied to his studies, and to the composition of various theological and moral works. Towards the close of his life he resided at Edessa, where he began to distinguish himself by his writings about the year 370, and was ordained deacon, determining not to accept of any higher ecclesiastical order. His works were all written in the Syriac language, and several of them were translated into Greek, with which he does not seem to have been acquainted, during his life. He was held in high estimation, on account both of his virtues and his writings. From Dr. Assemann we learn, that the Syrians gave him the titles of Doctor or Master of the whole world, and of their Prophet; and St. Jerome informs us, that his works were so much esteemed as to be publicly read in some churches after the Scriptures. Sozomen highly commends them both for style and sublimity of sentiment; which excellencies are said by this father, and also St. Jerome, to have been transfused into the Greek version of them. The subjects of these works were commentaries upon the Old and New Testaments; homilies, or sermons; exhortations to the monks; controversial pieces against Sabellius, Arius, Apollinaris, the Anomians, and the Novatians; treatises of morality; hymns to be sung in the churches; panegyrics, &c. of which we have an account by Cave, Du Pin, and Lardner. The most complete edition of the works of this writer was published at Rome, by Dr. Jos. Assemann, assisted by father Benedatti, a Jesuit, and Eyodius

Assemann, bishop of Apamea; which was begun in 1732, and finished in 1747, in 6 vols. folio, of which three are Syriac and Latin, and the other three Greek and Latin. St. Ephrem died about the year 378, under the reign of the emperor Valens; ordering his funeral to be conducted in a plain manner, and forbidding any eulogium to be delivered on the occasion, or any monument to be erected to his memory. With the acknowledged and applauded learning of Ephrem, a considerable degree of enthusiasm and fanaticism was blended; but his charitable disposition, which he manifested on a variety of occasions, endeared his name to survivors, and entitles him to honourable remembrance. Cave. Du Pin. Lardner. Jortin. Gen. Biog.

EPHREMI CODEX, in *Biblical History*, a manuscript of the New Testament, written on vellum, and supposed to be of very high antiquity. It is "Codex Regius 1905," noted in the catalogue of MSS. in the royal library in Paris IX., and in all the four parts of Wetstein's Greek Testament by the letter C. It is particularly described by Griesbach in his "Symbolæ," p. iii.—liv. The first part of it contains several Greek works of Ephrem the Syrian, written over some more ancient writings, which had been erased, though the traces are still visible, and in most places legible. These more ancient writings were the whole Greek Bible. The New Testament has many chasms, which are specified by Wetstein. Besides these chasms, it is in many places illegible. Wetstein contends that this MS. was written before the year 542, though his arguments are not wholly decisive. Its readings, like those of all other very ancient MSS., are in favour of the Latin; but no proof can be given that this has been corrupted from the Latin version. It has been altered by a critical collector, who, according to Griesbach, must have lived many years after the time in which the MS. was written, and has probably erased many of the ancient readings. Kuster was the first who procured extracts from it, and he inserted them in his edition of Mill's Greek Testament. Wetstein has repeatedly collated it with very great accuracy; and the numerous readings, which he has quoted from it, greatly enhance the value of his edition. A fac-simile of the characters of this MS., which is written without accents, is given by Montfaucou in his "Palæographia Græca." It has many marginal notes, written in uncial letters without accents. In this MS. the disputed, or rather spurious verse, John, v. 4, is written, not in the text, but as a marginal scholion. Wetstein supposed, that this was one of the MSS. which were collated at Alexandria in 616 with the new Syriac version; but though this does not appear to have been the case, it is certainly as ancient as the seventh century. Wetstein argues, from a marginal note to Heb. viii. 7, that it was written before the institution of the feast of the purification of the virgin Mary, that is, before the year 542. March's Michaelis, vols. ii. and iii.

EPHREMOS, or *YEPHREMOS*, in *Geography*, a town and district of Russia, in the government of Tula, situated on the river Metcha, falling into the Don.

EPHRON, in *Ancient Geography*, a place of Palestine, in the tribe of Judah, about 15 miles from Jerusalem, according to Eusebius and Jerome.—Also, a mountain of Palestine, on the confines of the tribes of Judah and Benjamin, according to the book of Joshua.—Also, a large and strong town of Judea, in the half-tribe of Manasseh, on the other side of Jordan, over-against Scythopolis. It was situated near the torrent of Jabok. This town was taken and sacked by Judas Maccabæus, and razed to its foundations.

EPHYDOR, *Εφυδωρ*, in *Antiquity*, an officer in the Athenian courts of justice, who was to provide the plaintiff and

and defendant with equal water hour-glasses. When the glass was run out, they were not permitted to speak any farther; and therefore we find them very careful not to lose or mispend one drop of their water. Whilst the laws quoted by them were reciting, or if any other business happened to intervene, they gave order that the glass should be stopped. Pott. Archæol. Græc. lib. i. cap. 21. lib. i. p. 118.

**EPHYRA**, in *Ancient Geography*, a town of Greece, in Thesprotia, a province of Epirus; mentioned by Velleius Paterculus and Strabo; the latter of whom says, that it was afterwards called *Cichyrus*.—Also, a town of Greece, in the Pelasgiotide, a country of Thessaly. This town was also called *Cranon*. Steph. Byz.—Also, a town of the Peloponnesus, in Arcadia. Steph. Byz.—Also, a town of the Peloponnesus, in the territory of Elis, situated on the river Selleis. This place was famous for the deadly poisons which it produced.

**EPI**, *Gr.* in *Music*, a preposition, which, like *hyper*, signifies *supra*, above. We find one of these words frequently added to the Greek names of some of the intervals of music; as

Epi, or hyper, { Diapason,  
Diapente,  
Diateffaron,  
Ditonum, &c.

When we meet with them thus in conjunction, they imply that the voice, in canons, is to follow the dux, or guide an octave, a fifth, a fourth, &c. below it. The third part is to observe the same rule with respect to the second, and the fourth to the third, and so on, whatever the number of parts may be.

**EPIACUM**, in *Ancient Geography*, a town of Albion, in the country of the Brigantes, according to Ptolemy. Camden places it at Elcheſter, on the river Derwent; Horsley at Hexham, in Northumberland; and Baxter supposes it was originally written Peliacum, and places it at Papcastle, in Cumberland.

**EPIALOS**, from *ἥσως*, gentle, and *ἄλς*, sea, in the *Medical Writings of the Ancients*, the name of a fever, in which the patient labours under a preternatural internal heat, while he at the same time shivers with cold. It has by some been called the shivering-fever, and the Romans named it *quercera*. Galen says, it proceeds from a putrid acid phlegm. The word is, by some, also applied to any gentle fever, or feverish complaint; and by others, to the cold or shivering fit preceding a fever. Hippocrates calls by this name that peculiar fever which attends young women, whose menses are stopped by taking cold, or other accidents.

**EPIAULIA**, a name which the Greeks gave to the Miller's Song. It is constantly confirmed, in inquiries after Greek music, that every profession, trade, and occupation, had its peculiar *nome*, tune, or song. Rousseau, so often satirical and sarcastic, but who seldom aims at pleasantry, has condescended to be joocular upon the Greek name for the miller's tune, by asking whether the burlesque word *piauler*, (whimpering, whining,) was not derived from the Greek; as the whimpering, whining, and squawling of women and brats, who cry and complain a long time in the same tone, sufficiently resemble the song or noise of a mill, and, by a metaphor, the miller?

**EPIBATÆ**, *Ἐπιβάται*, among the Greeks, marines or soldiers who served on board the ships of war. They were armed in the same manner as the land-forces, only that more of them wore full or heavy armour. Pott. Archæol. Græc. tom. ii. p. 140.

**EPIBATERION**, a poetical composition, in use among

the ancient Greeks. When any person of condition and quality returned home after a long absence or journey, into another country, he called together his friends and fellow-citizens, and made them a speech, or rehearsed them a copy of verses, wherein he returned solemn thanks to the immortal gods for his happy return; and ended with an address by way of compliment to his fellow-citizens.

These verses made what the Greeks call *ἐπιβάτηριον*, *epibaterium*, of *ἐπιβαίνω*, *I go abroad*. At going away they had another, called *ἀποβάτηριον*.

**EPIBATERIUM**, in *Botany*, from the Greek adjective *ἐπιβάτης*, climbing. Forst. Gen. 54. Schreb. 640. Willd. Sp. Pl. v. 4. 397. Juss. 285. Class and order, *Monocia Hexandria*. Nat. Ord. *Menispermæ*, Juss.

Gen. Ch. Male, *Cal.* Perianth double, deciduous; outer minute, flat, of six leaves; inner thrice as large, of three ovate spreading leaves. *Cor.* Petals six, smaller than the inner calyx, roundish; three of them external, placed between the calyx-leaves; three internal. *Stam.* Filaments six, capillary, incurved, the length of the petals; anthers roundish. Female, (on the same plant,) *Cal.* and *Cor.* as in the male. *Pist.* Germens three, superior, nearly globose; styles three, minute, incurved; stigmas spreading, compressed. *Peric.* Drupas three, roundish, pointed with the permanent styles. *Nut* kidney-shaped, compressed, slightly furrowed.

Ess. Ch. Male, Calyx double; the outermost of six, the inner of three leaves. Petals six, in two series. Stamens six. Female, Calyx and Corolla as in the male. Styles three. Drupas three, globular, pointed. Nuts solitary, kidney-shaped.

*E. pendulum* is the only species described, a native of the island of St. Jago. The stem is shrubby, climbing, with long pendulous branches. Leaves alternate, pointing one way, on short foot-stalks, oblong, entire, obtuse with a point, smooth and without ribs, about an inch long. Flowers minute, pale, on solitary, axillary, simple stalks.

**EPIBOMEUM**, the name of a cantic in the Greek music, which was sung before the altar.

**EPIC POEM**, an heroic poem, or a poem reciting some great and signal transactions of a hero; called also *ἑποποιία*. This kind of poem is universally allowed to be, of all poetical productions, the most dignified, and, at the same time, the most difficult in execution. To contrive a story which shall please and interest all readers, by being at once entertaining, important, and instructive; to fill it with suitable incidents; to enliven it with a variety of characters, and of descriptions; and to maintain, in the course of a long work, that propriety of sentiment, and that elevation of style, which the epic character requires, is unquestionably the highest effort of poetical genius. Hence it is that so few have succeeded in the attempt, and that strict critics will hardly allow any other poem to bear the name of epic, except the *Iliad* and the *Æneid*.

An epic poem, according to Bossu, is a discourse invented with art, to form the manners, by instructions disguised under the allegory of an important action related in verse, in a probable, entertaining, and surprising manner.

This definition, it has been observed, would suit *Æsop's fables*, if they were extended, and put into verse. Accordingly the critic draws a parallel between the construction of one of *Æsop's fables* and the plan of Homer's *Iliad*. The first thing, he says, which a writer of fables, or of heroic poems, does, is to choose some maxim or point of morality, designed to be inculcated in the work. He next invents a general story, or a series of facts, without any names, such as he conceives most proper for the illustration

of his intended moral. Lastly, he particularizes his story; that is, if he be a fabulist, he introduces his dog, his sheep, and his wolf; and if he be an epic poet, he draws from ancient history some proper names of heroes to be applied to his actors; and thus his plan is completed. This, says Dr. Blair, is one of the most frigid and absurd ideas that ever entered into the mind of a critic; nor can any person of just reflection and taste ever imagine, that Homer could have proceeded in this manner. No one, indeed, can entertain a doubt that the first objects which strike an epic poet are, the hero whom he is to celebrate, and the action, or story, which is to be the ground-work of his poem. "He does not sit down, like a philosopher, to form the plan of a treatise of morality. His genius is fired by some great enterprise, which to him appears noble and interesting; and which, therefore, he pitches upon as worthy of being celebrated in the highest strain of poetry. There is no subject of this kind, but will always afford some general moral instruction, arising from it naturally. The instruction, which Bossu points out, is certainly suggested by the Iliad; and there is another which arises as naturally, and may just as well be assigned for the moral of that poem; namely, that Providence avenges those who have suffered injustice; but that when they allow their resentment to carry them too far, it brings misfortunes on themselves. The subject of the poem is the wrath of Achilles, caused by the injustice of Agamemnon. Jupiter avenges Achilles, by giving success to the Trojans against Agamemnon; but by continuing obstinate in his resentment, Achilles loses his beloved friend Patroclus."

An epic poem is in its nature the recital of some illustrious enterprise in a poetical form. This definition is sufficiently exact; and hence it appears to comprehend several other poems besides the Iliad of Homer, the Æneid of Virgil, and the Jerusalem of Tasso; which are, perhaps, the three most regular and complete epic works that were ever composed. But to exclude all poems from the epic class, which are not formed exactly upon the same model as these, is, says Dr. Blair, the pedantry of criticism. This writer, therefore, does not scruple to class such poems, as Milton's Paradise Lost, Lucan's Pharsalia, Statius's Thebaid, Ossian's Fingal and Temora, Camoens's Lusiad, Voltaire's Henriade, Cambray's Telemachus, Glover's Leonidas, Wilkie's Epigoniad, under the same species of composition with the Iliad and Æneid. They are all, undoubtedly, epic; that is, poetical recitals of great adventures, and consequently belonging to this denomination of poetry.

The epic poem is distinguished from comedy, in that the action of the latter is not important, nor is related by the poet, but acted by the persons introduced for that purpose; which circumstance, likewise, distinguishes it from tragedy. It differs also from tragedy in the event, or conclusion; which, in the latter, is generally unfortunate, but seldom or ever so in the former. See ACTION.

Nor is it a philosophical poem, as that of Lucretius, or the Creation of sir R. Blackmore; nor a treatise of agriculture, or the like, as the Georgics of Virgil; those poems not being intended to form the manners; beside, that the instructions they contain are naked, simple, and direct, without any disguise or allegory. Which second circumstance likewise distinguishes it from a treatise of morality, written in verse; or a simple history in verse: add, that its being confined to one important action, distinguishes it from a poem which relates all the actions of a person's life.

M. de la Motte, indeed, in his controversy with madam Dacier, on the subject of Homer, maintains, that the

whole life of a hero may justly be made the subject of an epic poem: and even that the Lutrin of M. Boileau might pass for an epic poem; but he seemed afterwards to return to the common sentiment. In effect, the question is not as to the sense which may be annexed to the words epic poem, but the sense which custom has actually annexed to them.

If we had only regard to the etymology of the word epic, of *ἔπος, verse, poetry*, from *ἔπος, dico, I speak (relate)*, and poems wherein the poet speaks or rehearses things himself, without making the persons of his poems speak, except at second-hand, as he relates what they spoke on this or that occasion, would be properly epic poems; and so there is not an epigram, sonnet, or madrigal, but would come under that denomination: but this were wild.

In effect, the term epic poem is only attributed to a composition whose subject is great, instructive, and serious; that only comprehends one single principal event, to which all the rest refer; which principal action is to be terminated in a certain space of time, ordinarily about a year. It is true, all this is arbitrary; but the sense of all words is so too; and in matters of language we must be guided by custom.

If M. de la Motte had only pretended, that one might make a fine instructive poem on the whole life of a hero, or an agreeable and diverting poem on some humorous adventure, all the world would have been on his side. But it is enough that custom has not thought good to apply the term epic either to subjects of too much extent, and that are crowded with too many incidents no-way connected together; or to burlesque poems, as the Batrachomyomachia of Homer, the Secchia Rapita of Tassoni, the Défaite de Dulot, the Lutrin of Boileau, the Hudibras of Butler; the Rape of the Lock of Mr. Pope, or the Dispensary of Dr. Garth.

Dr. Blair cannot allow with Bossu and others, that it is the essence of an epic poem to be wholly an allegory, or a fable contrived to illustrate some moral truth; nevertheless, he admits, that no poetry is of a more moral nature than this. The effect, however, in promoting virtue is not to be estimated by any one maxim or instruction, which results from the whole story, like the moral of one of Æsop's fables; but from the impression which the parts of the poem separately, as well as the whole taken together, make upon the mind of the reader; from the great examples which it sets before us, and the high sentiments with which it warms our hearts. Its proposed end is to extend our ideas of human perfection, and thus to excite admiration; an end, which can be accomplished only by proper representations of heroic deeds and virtuous characters. Epic poems must, according to this statement of their object, be favourable to virtue. Moreover, the general strain and spirit of epic composition sufficiently mark its distinction from the other kinds of poetry. In pastoral writing, the reigning ideas are innocence and tranquillity; compassion is the great object of tragedy; and ridicule the province of comedy. But the predominant character of the epic is admiration excited by heroic actions. It is sufficiently distinguished from history, both by its poetical form, and the liberty of fiction which it assumes. It is a more calm composition than tragedy. It admits, nay, requires the pathetic and the violent on particular occasions; but the pathetic is not its general character. It requires more than any other species of poetry, a grave, equal, and supported dignity. It takes in a greater compass of time and action than dramatic writing admits; and thereby allows a more full display of characters. Dramatic writing displays characters chiefly by means of sentiments

ments and passions; epic poetry chiefly by means of actions. The emotions which it excites are, therefore, not so violent, but they are more prolonged. These, says Dr. Blair, are the general characteristics of this species of composition.

The epic poem may be considered under three heads; first, with respect to the subject, or action; secondly, with respect to the actors, or characters; and lastly, with respect to the narration of the poet.

The action must possess the following properties; it must be one, and entire, great, and interesting. (See ACTION and EPISODE. See also *ÆNEID*, *ILIAD*, *PARADISE LOST*, &c.) The actors or personages introduced in an epic poem must be discriminated by appropriate and well-supported characters; which is denominated by Aristotle giving manners to the poem. See CHARACTER, in *Poetry*.

If we examine the characters of Milton, we shall find that he has introduced all the variety which his fable was capable of receiving. The whole species of mankind was restricted to two persons at the time to which the subject of his poem relates. We have, however, four distinct characters in these two persons. We see man and woman in the highest innocence and perfection, and in the most abject state of guilt and infirmity; the two last characters are, indeed, very common and obvious, but the two first are not only more magnificent, but more novel than any characters either in Virgil or Homer, or indeed in the whole circle of nature. Milton was so sensible that the subject of his poem afforded him but few characters, as to be led to introduce two actors of a fictitious nature, in the persons of "Sin" and "Death," by which means he has wrought into the body of his fable a very beautiful and well invented allegory. However, it has been thought, that persons of such a chimerical existence are not proper actors in an epic poem; because there is not that measure of probability annexed to them, which is requisite in writings of this kind.

There is one circumstance, relating to the principal actors of the *Iliad* and *Æneid*, that merits particular notice, because it gives a peculiar beauty to these two poems, and was, therefore, contrived with very great judgment. This is the choice for their heroes of persons nearly related to the people for whom they wrote. Achilles was a Greek, and Æneas the remote founder of Rome. Their countrymen were thus rendered particularly attentive to all the parts of their story, and sympathized with their heroes in all their adventures. Milton's poem is also admirable in this respect; since it is impossible for any of its readers, to whatever nation, country, or people he may belong, not to be related to the persons who are the principal actors in it; but what is still infinitely more to its advantage, the principal actors in this poem are not only our progenitors, but our representatives. We have an actual interest in every thing they do, and no less than our utmost happiness is concerned, and lies, as it were, at stake in their whole behaviour.

Besides human actors, there are personages of another kind, that usually occupy no small place in epic poetry; such are the gods, or supernatural beings. This constitutes what is called the machinery of the epic poem; and it is the most nice and difficult part of the subject. About the necessity and use of machinery in an epic composition, critics have been divided. The French critics consider it as essential to the constitution of an epic poem; and they allege that a poem, though it should possess every other requisite, has no pretension to be ranked in the epic class, unless the main action be carried on by the intervention of the gods. This decision seems to be principally, if not solely, founded on a superstitious reverence for the practice of Homer and Virgil. But, although these poets very properly embellished their

respective story by the traditionary tales and popular legends of their own country, according to which, all the great transactions of the heroic times were intermixed with the fables of their deities; does it hence follow, that in other countries, and in other ages, which do not possess a similar advantage of current superstition, and popular credulity, epic poetry must be confined to antiquated fictions, and fairy tales? Lucan has composed a very spirited poem, certainly of the epic kind, where neither gods nor supernatural beings are at all employed. The author of Leonidas has also succeeded in an attempt of the same kind; and, without doubt, wherever a poet gives us a regular heroic story, well connected in its parts, adorned with characters, and supported with proper dignity and elevation, though his agents be every one of them human, he has fulfilled the chief requisites of this kind of composition, and has a just title to be classed with epic writers. Dr. Blair, whilst he cannot admit that machinery is indispensibly necessary or essential to the epic plan, differs from those critics of considerable name, who are for wholly excluding it, as inconsistent with that probability and impression of reality, which, as they conceive, should prevail in this kind of writing. (See *Elem. of Criticism*, ch. 22.) In epic poetry, where admiration and lofty ideas are supposed to reign, the marvellous and supernatural find, if any where, their proper place. They both enable the poet to aggrandize his subject, by means of those august and solemn objects which religion introduces into it; and they allow him to enlarge and diversify his plan, by comprehending within it heaven, and earth, and hell, men and invisible beings, and the whole circle of the universe.

In the use, however, of this supernatural machinery, a poet should be prudent and temperate. The system of the marvellous, which he introduces, should have some foundation in the popular belief, so that events, which are most contrary to the common course of nature, may derive from it an air of probability; and he should guard against excess in the use of it. As to allegorical personages, fame, discord, love, and the like, they form, says Dr. Blair, the worst machinery of any; and though they may serve for embellishment, they should not be permitted to bear any share in the action of the poem.

With regard to the narration in an epic poem, it is not of any great moment, whether the poet relate the whole story in his own character, or introduce some of his personages to relate any part of the action that had passed before the poem opens. Homer follows one method in his *Iliad*, and the other in his *Odyssey*. Virgil has, in this respect, imitated the conduct of the *Odyssey*; Tasso that of the *Iliad*. Where the subject is of great extent, and comprehends the transactions of several years; as in the *Odyssey* and the *Æneid*, the latter method seems preferable. When the subject is of smaller compass, and shorter duration, as in the *Iliad* and the *Jerusalem*, the poet may, without disadvantage, relate the whole in his own person. It is of very considerable importance in the course of the narration, that it be perspicuous, animated, and enriched with all the beauties of poetry. No sort of composition requires more strength, dignity, and fire, than the epic poem. "It is the region," says Dr. Blair (*Lectures on Rhetoric*, &c. vol. iii.) "within which we look for every thing that is sublime in description, tender in sentiment, and bold and lively in expression;" and, therefore, though an author's plan should be faultless, and his story ever so well conducted, yet, if he be feeble, or flat in style, destitute of affecting scenes, and deficient in poetical colouring, he can have no success. The ornaments which epic poetry admits must  
all

all be of the grave and chaste kind. Nothing that is loose, ludicrous, or affected, finds any place there. All the objects which it presents ought to be either great, or tender, or pleasing. Descriptions of disgusting or shocking objects should as much as possible be avoided; and, therefore, the fable of the Harpies, in the third book of the *Æneid*, and the allegory of Sin and Death, in the second book of *Paradise Lost*, had been better omitted in these celebrated poems. Mr. Addison, in his critique on the *Paradise Lost* (*Spectator*, vol. iv.), has introduced several pertinent remarks on this subject. The sentiments, which in an epic poem are the thoughts and behaviour ascribed by the author to the persons whom he introduces, should be conformable to the respective characters of these persons, and when this is the case they are said to be *just*. The sentiments have likewise a relation to *things* as well as to *persons*, and they are then perfect, when they are adapted to the subject. If in either of these cases the poet endeavours to argue or explain, to magnify or diminish, to raise love or hatred, pity or terror, or any other passion, we ought to consider whether the sentiments he makes use of are proper to those ends. Homer is censured by the critics for his defect as to this particular in several parts of the *Iliad* and *Odyssey*; but candour ascribes this defect to the times in which he lived. Virgil has excelled all others in the propriety of his sentiments. Milton is likewise commended in this respect; and he claims peculiar praise from the consideration, that most of his characters lie out of nature, and were to be formed purely by his own invention. The loves of Dido and *Æneas* are merely copies of what has passed between other persons. Whereas Adam and Eve, before the fall, are a different species from that of mankind, who are descended from them; and no one but a poet of the most unbounded invention, and the most exquisite judgment, could have introduced into their conversation and behaviour so many apt circumstances during their state of innocence. An epic poem should abound not only with such thoughts as are natural, but also with such as are sublime. In this respect Virgil is inferior to Homer. Indeed, Virgil seldom rises into sentiments that are astonishing, where he is not fired by the *Iliad*. He every where charms and pleases us by the force of his own genius; but seldom elevates and transports us where he does not deduce his hints from Homer. Milton's chief talent, and distinguishing excellence, lie in the sublimity of his thoughts. In the greatness of his sentiments he triumphs over all the poets both ancient and modern, Homer only excepted. As sentiments that are natural and sublime are always to be pursued in an heroic poem, there are two kinds of thoughts, which should be carefully avoided; the first are such as are affected and unnatural, and the second such as are mean and vulgar. In Virgil we meet with little or nothing that resembles the first kind of thought: none of those trifling points and puerilities that often occur in Ovid, none of the epigrammatic turns of Lucan, none of the swelling sentiments that are so frequent in Statius and Claudian, and none of the mixed embellishments of Tasso. Every thing is just and natural. Milton has sometimes erred in this respect; and it is urged as his apology, that he was infected by the taste and practice of the age in which he lived. Mean and vulgar thoughts have rendered Homer obnoxious to censure; but his advocates have imputed sentiments of this kind to the age in which he wrote, and to that which he described, rather than to any imperfection in that divine poet. No blemish of this kind is observable in Virgil, and Milton is seldom chargeable with it.

We have already observed, that the language of an

heroic poem should be both perspicuous and sublime. In proportion as either of these two qualities are wanting, the language is imperfect. See farther of the nature of the epic poem under *FABLE*. For its matter, see *ACTION*. For its form, see *NARRATION*. For its versification, see *HEXAMETER*. See also *MANNERS*, *CHARACTERS*, *MACHINE*, &c. See also *ÆNEID*, *ILIAD*, *TASSO'S Jerusalem*, *CAMOENS'S Lusiad*, *FENELON'S Telemachus*, *VOLTAIRE'S HENRIADE*, and *MILTON'S PARADISE Lost*.

*EPICAIROS*, in *Ancient Geography*, a town of Palestine, E. of Jordan. Ptolemy.

*EPICARIA*, a town of Illyria, in Dalmatia. Ptol.

*EPICAUMA*, (from *επι*, and *καυω*, to burn). See *EXCAUMA*.

*EPICEDION*, *Επικεδιον*, formed of *επι*, upon, and *κεδος*, funeral, in the *Greek and Latin Poetry*, was a funeral eulogy, or a composition in prose or verse, delivered over the corpse of a friend or neighbour, commemorative of the virtues of the deceased. In celebrating the obsequies of distinguished persons three kinds of funeral discourses were used on the occasion. One, delivered when the friends were assembled to perform the last mournful offices for the dead, was termed *epicedium*; another, at the rogos, bustum, or funeral pile, *nenia*; and that inscribed on the tomb or cenotaph, *epitaphium*. In the early ages of society, the *epicedium* was generally an extemporaneous effusion of some near relative or affectionate friend, expressive of the sentiments he felt at the loss, and calculated to excite the common sympathy of the surrounding attendants. Beautiful specimens are given of this species of postobituary respect by Virgil in the *Æneid*: the one (lib. ix.) on the death of Euryalus, and the other (lib. xi.) on the death of Pallas. But in subsequent periods, when wealth and luxury had supplanted the simplicity of nature, and truth of feeling had been obliged by fashion to yield to the flattery of pomp; the custom, though preserved, materially differed in its character and form. What once had been the proper expression of undissimulated esteem, was changed into a degrading system of pagantry and venality. In most public funerals, but more especially in those called *vindictivi*, the corpse, previous to interment, was carried into the forum, attended by a vast train of invited or hired followers, when one of the relatives, or some orator of eminence, ascended the rostrum, and harangued the audience in praise of the departed friend or hero. The origin of this custom is attributed to Valerius Publicola, after the expulsion of the regal title. He having honoured the obsequies of his colleague with a funeral oration, so pleased the vanity of the Roman people, that it soon became fashionable to celebrate the funerals of great or distinguished characters with panegyrics, or encomiastic orations. The practice became at length so popular, that the younger Pliny, in his epistle, lib. ii. ep. 1. considers it as the last, but not the least addition to the happiness of a great and good man, to have had the enviable honour of being commended at his funeral by the eloquence of the consul, Tacitus. Nor was this privilege exclusively confined to men; for Livy relates that the Roman matrons, having been extremely liberal and active in raising a collection of gold to enable the government to deliver the city from the hands of the Gauls, were allowed, by an act of the senate, to have the privilege of *epicedia* being pronounced at the celebration of their obsequies, equally with the other sex. The abuses to which this custom was liable, and to which it actually became in time subservient, are made the subjects of just complaint, and pointed animadversion, both by Cicero and Livy; as tending, by the fulsome flattery, to weaken the motives to virtue, and by the greater attention which

those posthumous orators paid to the blandishments of eloquence, than to the accurate statement of facts, to falsify the page, and corrupt the source of history. For on such occasions the orator did not fail to extol the deceased in the most unqualified terms of praise, to emblazon his virtues in the most brilliant colours, and to place to his credit noble actions which he had never achieved. Particularly when the orator entered on an investigation of the lineage of the party, he seldom failed to ally him to some patrician family, or dignify his pedigree, by associating with his name some of the most renowned characters in the commonwealth to illustrate and confirm the descent, so that gradually, by means of these misrepresentations being recorded, the epicedia tended to obliterate the just distinctions of consanguinity, and throw down the barriers of property. From this heathen custom are derived obituary masses, orations funebres, and funeral sermons.

EPICERASTICS, *Επικεραστικά*, formed of *επι* and *κερασμα*, *I moderate*, in *Medicine*, remedies which, by their temperate moisture, soften the acrimony of a humour, and assuage the painful sensation of a part irritated or afflicted by it; such are the roots of althæa, mallows, liquorice; leaves of lettuce, mallows, water-lily, purslain; the seeds of flax, poppy, &c. See *EMOLLIENTS*.

EPICHRMUS, in *Biography*, a native of the island of Cos, who flourished in the 5th century, B. C. His father removed him at an early age to Megara, and afterwards to Syracuse, where he became a disciple in the Pythagorean school. Being prevented, by the tyranny of Hiero, from assuming the public profession of philosophy, he chiefly applied himself to the study of dramatic poetry, and offended the Pythagoreans, by introducing the doctrines and precepts of Pythagoras upon the stage. His comedies were numerous, of which Suidas assigns to him 52; but only some few fragments remain. He taught a school at Syracuse, and is said to have invented the two Greek letters *θ* and *χ*. He also wrote commentaries upon physical and medical subjects. We have no accurate account of his philosophical tenets: but some of his apophthegms deserve to be recorded; such are the following: "To die is an evil; but to be dead is no evil." "Every man's natural disposition is his good or evil dæmon." "He who is naturally inclined to good is noble, though his mother was an Ethiopian." "Be sober in thought, be slow in belief; these are the sinews of wisdom." "The gods set up their favours at a price, and industry is the purchaser." "Live so as to be prepared either for a long life or a short one." According to Lucian, the life of Epicharmus was prolonged to the age of 97 years. Laert. l. viii. § 78. Suidas. Fabr. Bib. Græc. v. i. p. 676. Brucker's Phil. by Enfield, vol. i.

EPICHIREMA, *Επιχίρημα*, in *Logic*, an argumentation, consisting of four or more propositions, some of which are proofs of others.

Thus, that oration of Cicero for Milo may be reduced to the epichirema: "Those who way-lay a man to kill him, it is lawful for him to kill, as is allowed by the laws of nature and nations, and by the practice of the best men; but Clodius way-laid Milo with that view, as appears from his forming an ambuscade before his country-house, and from his provision of weapons, soldiers, &c." Therefore it was lawful for Milo to kill Clodius.

EPICHIROTONIA, among the Athenians. It was ordained by Solon, that once every year the laws should be carefully revised and examined; and if any of them were found unsuitable to the present state of affairs, they should be repealed. This was called *επιχίροτονία των νόμων*, from the

manner of giving their suffrages, by *holding up their hands*. See a farther account of this custom in Pott. Archæol. Græc. lib. i. cap. 26. tom. i. p. 142.

EPICHOORDIS, from *χορδή*, an *intestine*, in *Anatomy*, a name given by some to the mesentery.

EPICHUS, or TACAPE (*Gabs*), in *Ancient Geography*, a town of Africa, on the coast of the Mediterranean sea, S. of Tephura. See *GABS*.

EPICITHARISMA, in the *Ancient Music*, an air for the cithara, said to be played at the end of dramatic pieces; which, consequently, must have been to Greek plays what a terminating ballet is now to an opera.

EPICLEROS, *Επικληρος*, among the Athenians, a daughter that had no brothers, and therefore inherited her father's whole estate. See *EPIDICASIA*.

EPICÆNE, *Επικαινοι*, in *Grammar*, a term applied to nouns, which, under the same gender and termination, mark, indifferently, two kinds of sexes. See *GENDER*.

Such in Latin, are *aquila*, *vespertilio*, &c. which signify equally a male or a female eagle, or bat.

Grammarians distinguish between epicæne and common. A noun is said to be common of two kinds, when it may be joined either with a masculine or a feminine article; and epicæne, when it is always joined to some one of the two articles, and yet signifies both genders.

EPICOLIC REGION, in *Anatomy*, from *επι*, upon, and *κόλιον*, the colon, that part of the abdomen which is above the colon.

EPICRANIUS, a thin and broad muscle, covering the superior arched portion of the cranium, and called also fronto-occipitalis, and occipito-frontien; or described as two muscles by the names of frontalis and occipitalis.

If we describe this as a single muscle, which we consider as the most natural and correct method, it will belong to the class of digastric muscles, or of such as possess a middle tendon, with fleshy fibres connected to its two ends. The aponeurosis is a very broad but thin plane, made up of tendinous fibres, variously interwoven, covering the upper part of the cranium, and hence called by Soemmerring *galea crani aponeurotica*. It is separated, along the middle, by a narrow interval from the opposite muscle, and it extends externally as far as the semicircular line, to which the temporal fascia is affixed. Its outer surface adheres closely to the scalp, while the inner is much more loosely connected, by a yielding cellular substance free from fat, to the pericranium. Its edges are insensibly continued into the neighbouring cellular substance.

The frontal portion is a thin flattened layer of muscular fibres, commencing by a femilunar edge from the front of the aponeurosis, and descending in a straight course to the eyebrow. Internally it is continuous with the opposite muscle, and detaches a portion of fibres along the side of the nose, to join the compressor narium, and levator labii superioris and alæ nasi. It then terminates by joining the orbicularis palpebrarum, through the whole of its upper convexity, and it is also connected with the corrugator supercilii. The external surface of this muscle is covered by the integuments of the forehead; and its inner surface lies on the frontal bone and os nasi.

The occipital portion is not so broad as the preceding. Arising from the back edge of the aponeurosis, it is inserted into the upper part of the external transverse ridge of the occipital bone. It covers the occipital and a little of the temporal bone, and is covered by the scalp.

It is very obvious that the occipito-frontalis cannot affect the bones of the head; but it moves the integuments in different directions; in consequence of the connection between  
its

its tendon and the scalp. When the frontal and occipital portions act alternately, they draw the common tendon backwards and forwards, and thereby impart considerable motion to the whole hairy scalp. If they act together, they will render the aponeurosis tense. When the frontal acts separately, it draws up the eyebrow and skin of the forehead, and throws the latter into transverse wrinkles. Hence it is concerned in the expression of the countenance, and acts more especially in the gay and joyful emotions, directly antagonising the corrugator supercilii, which throws the forehead, and particularly the eyebrows, into longitudinal wrinkles. It contributes also, by means of its connection with the upper eyelids, to the opening of the eyelids, when we carry that to as great an extent as possible. The separate action of the occipital can only produce a slight effect on the integuments of the back of the head. Its contraction, however, fixes the aponeurosis, and renders it a firm point for the contraction of the frontal in raising the eyebrow and eyelid. This muscle, on the whole, is strongly analogous to the panniculus carnosus of quadrupeds.

EPICRASIS, in *Medicine*, is a gradual evacuation of ill humours in the blood.

EPICRISIS, *Ἐπικρίσις*, in *Rhetoric*, a clear and brief declaration of the speaker's judgment concerning the subject in hand. Thus, "ego sic statuo, in optimo imperatore quatuor has res inesse oportere, &c." Voss. *Rhet. lib. vi. p. 495*.

EPICTETI, in *Ancient Geography*, a people, who, according to Strabo, bounded Bithynia on the east. Hence the western part of Phrygia obtained the appellation of "Phrygia Epictetus." In this territory was the source of the river Hermus, and the town of Ancyra was situated in it, on the frontiers of Mysia.

EPICTETUS, in *Biography*, an eminent Stoic philosopher, no less distinguished for his virtues than his wisdom, was born in a servile condition at Hierapolis in Phrygia, and flourished in the first century of the Christian era. At an early age he was sold as a slave to Epaphroditus, a celebrated freedman of Nero, to whom Josephus inscribed most of his works, and who was afterwards put to death by Domitian. Epictetus was lame; and of this infirmity various causes have been assigned by different writers. Celsus relates, that when his master, in order to torture him, squeezed his leg very hard, the philosopher betrayed no symptoms of fear, but said very calmly to his tormentor; "You will break my leg;" and when it was broken, he only said with a smile, "Did I not tell you that you would break it." Some say, that he was born lame; and others ascribe his lameness to the heavy chains with which his master loaded him. Epictetus, having, by some means which are not recorded, obtained his freedom, retired to a small hut within the city of Rome, where, in an indigent condition, he devoted himself to the study of philosophy. Having in his retirement acquired a competent knowledge of the principles of the Stoic sect, and having also received instructions in rhetoric from Rufus; he became, notwithstanding his poverty, a popular preceptor of morals. He was an acute and judicious observer of manners; his eloquence was simple, majestic, nervous, and penetrating: his doctrine inculcated the purest morals; and his life was an admirable pattern of sobriety, magnanimity, and the most rigid virtue. His reprehensions of vice were bold and animated; his instructions and precepts impressive and conciliating; and they were communicated without that dogmatism, vanity, and rudeness, which were too generally affected by the philosophers. He was accustomed to observe, that the sum of

moral instruction may be comprised in two words, *ἀντὶς καὶ ἀπέχεσθαι*, i. e. endure and abstain, or bear and forbear. Aulus Gellius represents him as the greatest man the sect of the Stoics ever produced. The tyranny of Domitian, notwithstanding his extreme poverty and singular merit, included him in the number of those philosophers who were banished from Italy; and to the arbitrary decree of this monster, he calmly submitted, considering himself as a citizen of the world, and fully apprised, that wherever he went he carried his best treasure along with him. At Nicopolis in Epirus, which he chose as the place of his residence, he pursued his design of correcting vice and folly by the precepts of philosophy. The wisdom and eloquence of his discourses were held in such high estimation, that his hearers were very numerous, and it became a common practice among them to commit his instructions to writing. It is not certain whether he returned to Rome after the death of Domitian; but the respect which Adrian entertained for him renders it probable, that he spent the latter part of his life in that city. Here, however, he obtained no favours, that could induce him to abandon that humble condition of contented and independent poverty, which he had selected, and in which he determined to remain. Of the time and manner of his death we have no certain account. Themistius and Suidas assert that he lived till the time of the Antonines; but from the mention that is made of him by Aulus Gellius and Marcus Aurelius, it is probable that he died towards the close of the reign of Adrian. His name and memory were so much respected after his decease, that, according to Lucian, the earthen lamp, by which he used to study, was sold for 3000 drachmas, or more than 90% of our money. The testimony of Suidas, who asserts that Epictetus wrote many books, is not supported by any ancient author; however this be, the only remains of this philosopher are his beautiful moral manual, entitled "Enchiridion," and his "Dissertations," selected by Arrian, which were drawn up from notes taken by his disciples from his lips. Arrian's account of his life and death is not now extant. Simplicius has left a commentary upon his doctrine, in the eclectic manner. There are also various fragments of his wisdom preserved by Antoninus, Gellius, Stobæus, and others. Although the doctrine of Epictetus is less extravagant than that of any other Stoic, his writings every where breathe the true spirit of Stoicism. The tenet of the immortality of the soul was adopted and maintained by him with a degree of consistency suited to a more rational system than that of the Stoics, who inculcated a renovation of being in the circuit of events, according to the inevitable order of fate; and his exhortations to contentment and submission to Providence are enforced on much sounder principles than those of the Stoics. He also strenuously opposed the opinion held by the Stoics in general, concerning the lawfulness of suicide; and his whole system of practical virtues approaches nearer than that of any other instructor, unenlightened by revelation, to the purity of Christian morality. We have various editions of the remains of this philosopher, published at Leyden in 1670, in 8vo. cum notis variorum; at Utrecht in 1711, in 4to.; at Oxford, in 1740, in 8vo. by Joseph Simpson, together with the Table of Cebes, &c.; at London in 1742 by J. Upton, in two volumes 4to. which is the most valuable of all. The Enchiridion was published by C. G. Heyne, in 1776, in 8vo. and, together with Cebes's table, by Schweighauser, in 1798, 8vo. These have been translated into various languages; but the most esteemed version in our country is that by Mrs. Carter, published in 1758, with notes. Fabr. *Bib. Græc. v. iii. Aul. Gell. l. i. c. 2. ## EPICUREANS.

t. iv. Adv. Indoct. lib. cment. t. ii. Brucker's Hist. Phil. by Enfield, vol. ii.

EPICUREANS, a sort of ancient philosophers, who adhered to the doctrines and opinions of Epicurus. See EPICURUS.

The doctrines of Epicurus, as they are stated in a just, comprehensive, and elaborate detail by Brucker in his "History of Philosophy," translated and abridged by Dr. Enfield, are arranged under the distinct heads of Philosophy in general, canons or rules of philosophising, Physics, and Ethics. Philosophy is the exercise of reason in the pursuit and attainment of a happy life; whence it follows, that those studies which conduce neither to the acquisition nor the enjoyment of happiness are to be dismissed as of no value. The end of all speculation ought to be, to enable men to judge with certainty what is to be chosen, and what to be avoided, to preserve themselves free from pain, and to secure health of body and tranquillity of mind. Accordingly, the young should apply to the study of it without delay, nor should the old be ever weary in the pursuit of it. As nothing ought to be dearer to a philosopher than truth, he should prosecute it by the most direct means, devising no fictions himself, nor suffering himself to be imposed upon by the fictions of others, neither poets, orators, nor logicians; making no other use of the rules of rhetoric or grammar, than to enable him to speak or write with accuracy and perspicuity, and always preferring a plain and simple to an ornamented style. A wise man will embrace such tenets, and only such, as are built upon experience, or upon certain and indisputable axioms. Philosophy consists of two parts:—physics, which respect the contemplation of nature; and ethics, which are employed in the regulation of manners. Of these, the latter is the most important; the knowledge of nature being only necessary as a means of promoting the happiness of life. Philosophers have added a third part, dialectics; which ought to be rejected, as only productive of thorny disputes, idle quibbles, and fruitless cavilling. In order to facilitate the pursuit of knowledge, a few plain maxims and rules may be useful. Truth is of two kinds; that which respects real existence, and that which consists in a perfect agreement between the conception of the mind and the nature of things. In order to judge rightly concerning truth, it is necessary to use some criterion, or instrument, of judging. This criterion will vary according to the nature of the object which the mind contemplates. In judging of natural and moral objects, the three instruments employed are sense, preconception, and passion. The maxims, or canons, pertaining to sense, are four: First, that the senses can never be deceived, and consequently, that every perception of an image, or appearance, is true; that is, that the perception, or simple apprehension, and its efficient cause, the species or image flowing from the object, really agree. Secondly, opinion, or judgment, is consequent upon perception, and admits of truth or falsehood. Perceptions, or sensations, are the effect of real external *phenomena*; but when the mind judges concerning these appearances, the opinion may be either right or wrong. Thirdly, every opinion is to be admitted as true, which is attested, or not contradicted, by the evidence of the senses, after a careful and deliberate examination of every circumstance which can be supposed to affect the question. Fourthly, an opinion contradicted, or not attested by the evidence of the senses, is false. Thus, the opinion of a *Plenum* must be false, because it contradicts the evidence of the senses, which attest, that there is such a thing as motion. Concerning the second instrument of judgment, *viz.* *πρόληψις*,

or pre-conception, four canons may be laid down. First, that all pre-conceptions are derived from the senses, either by immediate impression, as of an individual man; by enlargement or diminution, as of a giant or dwarf; by resemblance, as of an unknown city to one which has been seen; or by composition, as of a centaur. Secondly, pre-conception is necessary to enable us to reason, inquire, or judge of any thing. Thirdly, pre-conceptions, or universal notions, are the principles of all reasoning and discourse; and we easily refer to these in comparing one thing with another. If these notions be agreeable to nature, and distinctly conceived, artificial reasoning will be unnecessary. Fourthly, truths, not self-evident, are to be deduced from manifest pre-conceptions; or, where the relation of ideas is obscure, it is to be made evident by the intermediate use of some acknowledged principle. The third instrument, passion, or affection, which comprehends pleasure and pain, admits of the following four evident maxims. First, all pleasure, to which no pain is annexed, is for its own sake to be pursued. Secondly, all pain, to which no pleasure is annexed, is for its own sake to be avoided. Thirdly, that pleasure, which either prevents the enjoyment of a greater pleasure, or produces a greater pain, is to be shunned. Fourthly, that pain, which either removes a greater pain, or procures a greater pleasure, is to be endured. As to the use of words, two canons are sufficient. First, in speaking, use terms in common use, and in the sense in which they are commonly understood. Secondly, in hearing, or reading, attend carefully to the signification which the speaker or writer affixes to his terms. Attention to these maxims would prevent much obscurity and confusion, and terminate many disputes. By these rules Epicurus undertook to conduct his followers into the secrets of nature, and to lay open to them the origin of things.

The physical doctrine of Epicurus was as follows: Nothing can ever spring from nothing, nor can any thing ever return to nothing. The universe always existed, and will always remain; for there is nothing into which it can be changed. There is nothing in nature, nor can any thing be conceived, besides body and space. Body is that which possesses the properties of bulk, figure, resistance, and gravity: it is this alone which can touch and be touched. Space, or *vacuum*, destitute of the properties of body, incapable of action or passion, is the region which is or may be occupied by body, and which affords it an opportunity of moving freely. The existence of bodies is attested by the senses. Space must also exist, in order to allow bodies place in which to move and exist; and of their existence and motion we have the certain proof of perception. Besides body and space, no third nature can be conceived. But the existence of qualities is not precluded, because these have no subsistence except in the body to which they belong. The universe, consisting of body and space, is infinite. Bodies are infinite in multitude; space is infinite in magnitude. The universe is immovable, because there is no place beyond it into which it can move. It is also eternal and immutable, since it is liable to neither increase nor decrease, to production nor decay. Nevertheless, the parts of the universe are in motion, and are subject to change. All bodies consist of parts, which are either themselves simple principles, or may be resolved into such. These first principles, or simple atoms, are divisible by no force, and therefore must be immutable. The existence of such atoms is indisputable, because it is impossible that any thing which exists should be reduced to nothing. A finite body cannot consist of parts infinite either in magnitude or number; and therefore divisibility of bodies *in infinitum* is inconceivable. All atoms are of the same

## EPICUREANS.

nature, without any difference in essential qualities; and yet it appears, from their different effects upon the senses, that they differ in magnitude, figure, and weight. Atoms exist in every possible variety of figure; and yet on account of their solidity, they are infrangible, or incapable of actual division. Gravity is an essential principle of atoms; for being perpetually in motion, or making an effort to move, they must be moved by an internal impulse, which may be called gravity. By this internal force, atoms are carried forward in a direction, which is nearly rectilinear; and whilst they pass through free space, their declination from a right line occasions a casual concurrence of corpuscles of different forms. Thus various kinds of curvilinear motion will be produced. Moreover, when one atom is reflected from another, and again repelled by a third, it will acquire a kind of vibratory or tremulous motion. Hence an universal agitation will ensue. The principle of gravity, being essential to the primary corpuscles or atoms, these must have been incessantly, and from eternity, in actual motion; and with a velocity, when no obstacle intervenes, which will cause them to pass through the greatest imaginable space in the smallest imaginable portion of time. All atoms are also supposed, whilst they pass without resistance through the same empty space, to move with equal velocity; and though, by collision, their direction may be changed, their velocity is not diminished. Atoms are the elements from which all things are compounded, and into which they are resolved; and the energy, or principle of motion, which essentially belongs to them, is the sole agent in the operations of nature. Action originates in atoms, and from these proceeds to compound bodies. All the changes which take place in the figure, and other properties of bodies, consist in local motion. Bodies are more or less rare, in proportion to the size of the vacancies which intercept the solid atoms of which they are composed. Transparency depends partly upon the same cause, and partly upon the position of the vacancies between the particles: for rays of light will pass easily through a dense body, as glass, if its vacancies be placed in a straight line. Hardness and softness, flexibility, ductility, and other qualities, may be explained in a similar manner. The weight of a body is the result of the weight of all its atoms; and since gravity is an essential property of all atoms, all bodies must be heavy; and the only reason why some bodies appear to have the contrary principle of levity is, that they are driven upwards by the denser mass in which they are placed. Heat is the influx of certain small, round, soft corpuscles, which insinuate themselves into the pores of bodies in continual succession, till by their perpetual action, the parts are separated, and at length the body dissolved. The sense of heat is the perception of the separation of parts, which were before contiguous. Cold is the influx of certain irregular atoms, whose motion is slower than that of those which occasion heat, and their effect the reverse of the former. Pleasure and pain, motion and rest, and even time, are actions of bodies. Production and dissolution are nothing more than a change of the position of atoms, or an increase or diminution of the particles of which bodies are composed. The world is finite and terminable, and must have some figure, though this cannot possibly be ascertained. It is not eternal, but began at a certain time to exist; for since every thing in the world is liable to vicissitudes of production and decay, the world itself must partake of them. This may also be inferred from the short date of history, and the late invention of arts.

The formation of the world may be conceived to have happened in the following manner: a finite number of that

infinite multitude of atoms, which, with infinite space, constitutes the universe, falling fortuitously into the region of the world, were in consequence of their innate motion collected into one rude and indigested mass. In this chaos, the heaviest and largest atoms, or collections of atoms, first subsided, whilst the smaller, and those which from their form would move most freely, were driven upwards. These latter, after many reverberations, rose into the outer region of the world, and formed the heavens. Those atoms, which by their size and figure were suited to form fiery bodies, collected themselves into stars: those which were not capable of rising so high in the sphere of the world, being disturbed by the fiery particles, formed themselves into air. At length from those which subsided was produced the earth. By the action of air, agitated by heat from the heavenly bodies upon the mixed mass of the earth, its smoother and lighter particles were separated from the rest, and water was produced, which naturally flowed into the lowest places. In the first combination of atoms, which formed the chaos, various seeds arose, which, being preserved and nourished by moisture and heat, afterwards sprung forth in organized bodies of different kinds. Of the animal productions of the earth, some may be conceived to have been produced imperfect, and therefore incapable of life, but others would come forth more perfect. These, after the earth was exhausted of its seminal virtues, would respectively continue their species. The world, thus formed, would be preserved by the same mechanical causes which produced it; but by the incessant motion of atoms, which alone are solid and incorruptible, it would gradually tend to dissolution. In process of time nothing will remain but separate atoms and infinite space. As atoms are infinite, the number of worlds may also be infinite. The earth occupies the middle part of the world; but no point within it is properly the centre of gravity, for all heavy bodies fall in nearly parallel lines. The doctrine of Antipodes, according to the Epicurean philosophy, is false. The figure of the earth is a circular plane; and it is preserved from falling towards the lower region by the air, with which it is congenial, and upon which therefore it does not press; their mutual action destroying the effect of gravity. Earthquakes are caused by the agitation of internal winds and water, or by the decay or sudden fall of columns, that support portions of the earth's surface. Or, the internal winds may be converted into fires, which may cause sudden and violent eruptions, as in mount *Ætna*. Waters passing out of the sea into the crevices of the earth, undergo a filtration, by which the particles of salt received by them from the bed of the sea are separated. Fossils and plants are produced by the motion of atoms, that cause the continual transposition, accretion or diminution of individual bodies. Having no vital principle, they can only be said analogically to live or die. Animals having been once formed, at the beginning of the world, by the casual conjunction of similar atoms, the production of animal bodies is still continued in a consistent and determinate order. The parts of animals were not originally framed for the uses to which they are now applied; but, having been accidentally produced, they were afterwards accidentally employed. The eye, for example, was not made for seeing, nor the ear for hearing, but the soul, being formed within the body at the same time with these organs, and connected with them, could not avoid making use of them in their respective functions. The soul is a subtle corporeal substance, composed of the finest atoms; which, by the extreme tenuity of its particles, is able to penetrate the whole body, and to adhere to all its parts. It is composed

## EPICUREANS.

of four distinct parts; fire, which causes animal heat; an ethereal principle, which is moist vapour; air; and a fourth principle, which is the cause of sensation. These four parts are so perfectly combined as to form one subtle substance, which, whilst it remains in the body, is the cause of all its faculties, motions, and passions, and which cannot be separated from it, without producing the entire dissolution of the animal system. Different sensations are the casual effects of the different organs, which the soul in its union with the body is capable of employing, and of the different properties and qualities of external objects. These become sensible by means of certain species, or images, which are perpetually passing like thin films from bodies, in form similar to the surfaces of the bodies themselves, and striking upon organs fitted to receive them. The mind, or intellect, which is endued with the power of thinking, judging, and determining, is formed of particles most subtle in their nature, and capable of the most rapid motion. This intellect is a portion of the soul, forming with it one nature, and yet retaining its distinct character, which is the power of thinking; the supposed seat of it is the middle of the breast, or the heart, which we perceive to be the region of those affections which are excited by cogitation. Thought is produced by subtle images, which find their way through the body, and, when they arrive at the intellect, move it to think. The affections and passions of the soul may be reduced to two, pleasure and pain. Voluntary motion is the effect of images conveyed to the mind, by which pleasurable or painful conceptions are formed, and subsequent desires or aversions are produced, which become the immediate springs of action. Sleep is produced, when the parts of the soul, which are at other times diffused through the body, are expressed or separated by the action of the air, or of food. Dreams are the effect of images casually flying about, which from their extreme tenuity penetrate the body and strike upon the mind, exciting an imaginary perception of those things, of which they are images. Death is the privation of sensation, in consequence of the separation of the soul from the body; in which case, the soul is dispersed into the corpuscles or atoms of which it was composed, and therefore can no longer be capable of thought or perception. The knowledge of things, which belong to the regions above the earth, whether aerial or celestial, is to be pursued only for freeing the mind from imaginary fears, and settling it in a state of tranquillity. In the heavens, or ethereal regions, the sun, moon, and stars appear to be fiery bodies; or they may be smooth mirrors, from which bright fiery particles flowing through the ethereal regions are reflected to the earth; or they may be deep vessels, containing fires; or they may be circular plates heated like mortar, or stones in a furnace. The apparent motion of the heavenly bodies may arise from the revolution of the whole heaven in which they are fixed, like nails in a solid body: or by the revolution of the bodies themselves through the heaven as a fluid and permeable medium. The cause of this motion may be, either an internal necessity in the natures of the bodies themselves, or the external pressure of some ethereal fluid.

In the universe there are, according to Epicurus, without contradiction, divine natures; because nature itself has impressed the idea of divinity upon the minds of men. The notion is universal, nor is it established by custom, law, or any human institution; but it is the effect of an innate principle, producing universal consent, and therefore it must be true. This universal notion has probably arisen from images of the gods, which have casually made their

way into the minds of men in sleep, and have afterwards been recollected. But it is inconsistent with our natural notions of the gods, as happy and immortal beings, to suppose that they encumber themselves with the management of the world, or are subject to the cares and passions which must attend so great a charge. Hence it is inferred, that the gods have no intercourse with mankind, nor any concern with the affairs of the world. Nevertheless, on account of their excellent nature, they are objects of reverence and worship. In their external shape the gods resemble men; and though the place of their residence is unknown to mortals, it is without doubt the mansion of perfect purity, tranquillity, and happiness.

Upon a review of the preceding summary of the Epicurean system, furnished chiefly by Laetius and Lucretius, it must appear to be a feeble and ineffectual effort to explain the phenomena of nature upon mechanical principles. With this view Epicurus adopts a variety of wild and fanciful hypotheses, which evince his incapacity of solving the grand problem concerning the origin and formation of the world. But the greatest defect of this system is the attempt of its author to account for all the appearances of nature, even those which respect animated and intelligent beings, upon the simple principles of matter and motion, without introducing the agency of a Supreme Intelligence, or admitting any other idea of fate, than that of blind necessity inherent in every atom, by which it moves in a certain direction. Hence he leaves unexplained those appearances of design, which are so manifest in every part of nature, and absurdly supposes, that the eye was not made for seeing, nor the ear for hearing. Besides the idea which he gives of the nature of the gods, whose existence he admits, as similar to man; and of their condition, as wholly separate from the world, and enjoying no other felicity except that which arises from inactive tranquillity, falls infinitely short of the true conception of Deity, as the intelligent Creator and Governor of the world.

The doctrine of Epicurus concerning nature differs from that of the Stoics, (see *Stoics*,) chiefly in the following particulars: while the latter held God to be the soul of the world, diffused through universal nature, the former admitted no primary intelligent nature into his system, but held atoms and space to be the first principles of all things; and whilst the Stoics conceived the active and passive principles of nature to be connected by the chain of fate, Epicurus ascribed every appearance in nature to a fortuitous collision and combination of atoms. See *ATOMICAL* and *CORPUSCULAR Philosophy*.

The ethics of Epicurus are much less exceptionable than his physics; of which we may judge from the following summary. The end of living, or the ultimate good, which is to be sought for its own sake, according to the universal opinion of mankind, is happiness: which men generally fail of attaining, because they form wrong notions of the nature of happiness, or do not use proper means for attaining it. The happiness, which belongs to man, is that state in which he enjoys as many of the good things, and suffers as few of the evils incident to human nature as possible, passing his days in a smooth course of permanent tranquillity. Perfect happiness cannot possibly be possessed without the pleasure that attends freedom from pain, and the enjoyment of the good things of life. Pleasure is in its nature good, and ought to be pursued; and pain is in its nature evil, and should be avoided. Besides, pleasure or pain is the measure of what is good or evil in every object of desire or aversion. However, pleasure ought not in every instance to be pursued, nor pain to be avoided; but reason is to distinguish

## EPICUREANS.

guish and compare the nature and degrees of each, that the result may be a wise choice of that which shall appear to be, upon the whole, good. That pleasure is the first good appears from the inclination which every animal, from its first birth, discovers to pursue pleasure and avoid pain; and is confirmed by the universal experience of mankind, who are incited to action by no other principle, than the desire of avoiding pain, or obtaining pleasure. Of pleasure there are two kinds; one consisting in a state of rest, in which both body and mind are free from pain: the other arising from an agreeable agitation of the senses, producing a correspondent emotion in the soul. Upon the former of these, the enjoyment of life chiefly depends. Happiness may, therefore, be said to consist in bodily ease and mental tranquillity. It is the office of reason to confine the pursuit of pleasure within the limits of nature, so as to attain this happy state; which neither resembles a rapid torrent, nor a standing pool, but is like a gentle stream, that glides smoothly and silently along. This happy state can only be attained by a prudent care of the body, and a steady government of the mind. The diseases of the body are to be prevented by temperance, or cured by medicine, or endured tolerably by patience. Against the diseases of the mind philosophy provides sufficient antidotes; the virtues are its instruments for this purpose; the radical spring of which is prudence, or wisdom, and this instructs men to free their understandings from the clouds of prejudice; to exercise temperance and fortitude in the government of themselves; and to practise justice toward all others. In a happy life, pleasure can never be separated from virtue. A prudent man will consult his natural disposition in the choice of his plan of life. Temperance is that discreet regulation of the desires and passions, by which we are enabled to enjoy pleasures without suffering any consequent inconvenience. They who maintain such a constant self-command, as never to be enticed by the prospect of present indulgence to do that which will be productive of evil, obtain the truest pleasure by declining pleasure. Sobriety, as opposed to inebriety and gluttony, teaches men that nature is satisfied with a little, and enables them to be contented with simple and frugal fare: thus health is preserved; the offices of life are performed with alertness and activity; and the occasional varieties of a plentiful board acquire an excellent relish, and a person is prepared to meet every reverse of fortune without the fear of want. Continence, which is a branch of temperance, prevents the diseases, infamy, remorse, and punishment to which those are exposed, who indulge themselves in unlawful amours. Music and poetry, which are often employed as incentives to licentious pleasure, are to be cautiously and sparingly used. Gentleness, as opposed to an irascible temper, greatly contributes to the tranquillity and happiness of life, by preserving the mind from perturbation, and arming it against the assaults of calumny and malice. Moderation in the pursuit of honours or riches, is the only security against disappointment and vexation. A wise man will, therefore, prefer the simplicity of rustic life to the magnificence of courts. As the events of futurity are uncertain, he neither will be elated with confident expectation, nor depressed by doubt and despair; the one and the other being equally destructive of tranquillity. It will contribute to the enjoyment of life, to consider death as the perfect termination of a happy life, which it becomes us to close like satisfied guests, neither regretting the past, nor anxious for the future. Fortitude, by enabling us to endure pain and banish fear, is of great use in producing tranquillity. Philosophy instructs us to pay homage to the gods, not through hope or fear, but from veneration of their superior nature. It enables us also to conquer the fear of death, by

teaching us, that it is no proper object of terror; since, whilst we are, death is not, and when death arrives, we are not; so that it concerns neither the living nor the dead. The only evils to be apprehended are bodily pain and distress of mind. It becomes a wise man to endure the former with patience and firmness, because, if it be slight it may be easily borne; and if it be intense, it cannot last long. Mental distress commonly arises, not from nature, but from opinion; a wise man, will, therefore, arm himself against this kind of suffering, by reflecting that the gifts of fortune, the loss of which he may be inclined to deplore, were never his own, but depended upon circumstances which he could not command. If, therefore, they happen to leave him, he will endeavour as soon as possible to obliterate the remembrance of them, by occupying his mind in pleasant contemplation, and engaging in agreeable avocations. Justice respects man as living in society, and is the common bond without which no society can subsist. This virtue, like the rest, derives its value from its tendency to promote the happiness of life. It is the interest of every individual in a state of society to conform to the laws of justice, for in society, the necessity of the exercise of mutual justice, in order to the common enjoyment of the gifts of nature, is the ground of those laws by which it is prescribed. Nearly allied to justice are the virtues of beneficence, compassion, gratitude, piety, and friendship. He who confers benefits upon others, procures to himself the satisfaction of seeing the stream of plenty spreading around him from the fountain of his own beneficence; at the same time he enjoys the pleasure of being esteemed by others. The exercise of gratitude, filial affection, and reverence for the gods, is necessary, in order to avoid the hatred and contempt of all men. Friendships are contracted for the sake of mutual benefit; but by degrees they ripen into such disinterested attachment, that they are continued without any prospect of advantage. A true friend will partake of the wants and sorrows of his friend, as if they were his own; if he be in want, he will relieve him; if he be in prison, he will visit him; if he be sick, he will come to him; nay, situations may occur, in which he would not scruple to die for him. It cannot then be doubted, that friendship is one of the most useful means of procuring a secure, tranquil, and happy life.

From the preceding summary of the ethics of Epicurus, we may be enabled to refute the censures which many writers have passed upon him, as the preceptor of luxurious and licentious pleasures. These censures have originated in a misconception of the nature of that pleasure which he recommends and justifies, and which, in his system, is only another name for happiness. Whilst the Stoics taught that virtue itself is happiness, Epicurus maintained, that the motive by which men are induced to practise virtue is the desire of happiness. Both taught, that it is impossible to be happy without virtue, and both supposed virtue to consist in a conformity to nature. Whatever errors and absurdities may be justly charged on the Epicurean system, it must be allowed that, when candidly and fairly interpreted, it afforded no encouragement to immoral conduct. However, it cannot be denied by its most zealous advocates, that by the erroneous representations of the gods, and the disbelief of providence and the immortality of the soul, which this system propagated, it served very much to relax the obligations and enfeeble the sanctions and motives of virtue. This was actually the case both at Athens and at Rome, where those who belonged to the school of Epicurus, partly disseminating his genuine doctrine and partly perverting it, disgraced the system to which they adhered by the laxity and dissoluteness of their manners. Some indeed have expressed

pressed a doubt, whether Epicurus himself disbelieved the immortality of the soul. (See the notes upon "Cudworth's Intellectual system of the Universe," subjoined by Dr. Mosheim to his Latin translation of that learned work, vol. i. p. 66. 500. vol. ii. p. 1174.) His followers, however, seem to have been more explicit on this subject; and Mosheim asserts (Ecl. Hist. v. i. p. 167.) that towards the close of the second century of the Christian era, of all the philosophers, the Epicureans enjoyed the greatest reputation, and had undoubtedly the greatest number of followers, because their opinions tended to encourage the indolent security of a voluptuous and effeminate life, and to banish the remorse and terrors that haunt vice, and naturally incommode the wicked in their sensual pursuits. Hence it is certain, that in the common use of the appellation, Epicurean has been understood to signify an indolent, effeminate, and voluptuous person, who only consults his particular and private pleasure, without concerning himself with any thing serious. Accordingly it has been maintained, that there were always two kinds of Epicureans, the rigid and the remiss. The rigid Epicureans were those who were strictly attached to the sentiments of Epicurus, and who placed their whole happiness in the true pleasures of the mind, resulting from the practice of virtue. The loose or remiss Epicureans, taking the words of that philosopher in a more gross sense, placed all their happiness in corporeal gratifications and pleasures, in eating, drinking, &c. Those of the former class, who were the genuine Epicureans, called the others the "Sophists of their sect." In the "Nouveau Dictionnaire Historique" the reader may find a short account of modern Epicurean schools in France, the members of which were more distinguished by their literary refinement, polished manners, and luxurious indulgence, than their culture of the genuine doctrine of the Greek philosopher.

Before we close this article, we shall briefly trace the subsistence and progress of the Epicurean school, after the death of its founder. From Epicurus the charge of it devolved upon his friend Hermachus; and it was continued in succession by Polystratus, Basilides, Protarchus, and others. The sect subsisted, in a depraved and degraded state, till the decline of the Roman empire. It entered Rome, indeed, in consequence of the opposition excited against it by the Stoics in Greece, under a heavy load of obloquy. This was much increased by the vehemence with which Cicero, (*De Fin.* l. ii. *Tusc. Qu.* l. 1. 3. *Fam. Ep.* xiii. 1. *Orat.* in *Pison.* c. 22.) inveighed against this sect, and by the easy credit which he gave to the calumnies indudtriously circulated against its founder. It was, however, patronized by several persons of distinction in Rome, and particularly by Atticus, the bosom friend of Cicero. Nevertheless, the true doctrine of Epicurus was not fully stated by any Roman writer, till Lucretius, with much accuracy of conception and clearness of method, as well as with great strength and elegance of diction, unfolded the Epicurean system in his poem, "*De Rerum Naturâ*," "*On the Nature of Things*." The Epicurean sect, though much degenerated from the simple manners of its founder, continued to flourish through a long course of years under the Roman emperors. This was owing in part to the freedom of manners which it permitted, and in part to the boldness with which it combated superstition; but principally to the strict union which subsisted among the members of this school, and the implicit deference which they unanimously agreed to pay to the doctrines of their master. The succession of disciples in this sect was, as Laertius attests (*l. x. § 9.*) uninterrupted, even when other schools began to fail. In many places the doctrine of Epicurus was publicly taught, and at Athens

the Epicurean school was endowed with a fixed stipend. Among the learned men of this period there were some, whose whole concern was to transmit the tenets and maxims of Epicurus uncorrupted to posterity; and others, who held the memory of Epicurus in high estimation, and in many particulars adopted his doctrine, and who, therefore, may not improperly be ranked in the class of Epicureans. The principal of these are Pliny the elder, Celsus, Lucian, and Diogenes Laertius. After the revival of letters at a much later period, there were not wanting several learned men, who, finding little satisfaction in the obscure and subtle speculations of metaphysics, had recourse to the doctrine of Epicurus, as the true key to the mysteries of nature. The first restorer of the Epicurean system among the moderns was Daniel Sennert, an eminent physician of Wittenburg, who flourished at the beginning of the 17th century. Sennert, however, confounded the corpuscles of the more ancient philosophers with the atoms of Democritus and Epicurus, and held that each element has primary particles peculiar to itself. The same doctrine was taught, with some inconsiderable variations, by Chrysothom Magnenus, professor of medicine in the university of Pavia, who, in the year 1646, published "*A treatise on the Life and Philosophy of Democritus*." His system is rendered obscure by an attempt to unite the incompatible dogmas of Epicurus and Aristotle. The ablest and most successful attempt towards the revival of the physical and moral philosophy of Epicurus was made by Peter Gassendi, who, besides a variety of other learned treatises, wrote a life of Epicurus, in which he undertakes to rescue that philosopher from the load of calumny under which his memory had lain for many ages, as well as to give a fair and impartial representation of his doctrine. The most celebrated followers of Gassendi were Francis Bernier, a physician of Montpellier, who wrote an "*Abridgement of Gassendi's Philosophy*," Par. 1678, and Walter Charlton, an Englishman, who wrote a treatise, entitled "*Physiologia Epicuro-Gassendo-Charletoniana*," Lond. 1654, in which he attempts to establish natural science upon atomic principles. Indeed, the doctrine of atoms and a vacuum has been embraced by the most eminent philosophers. Huygens applies it to explain the cause of gravitation, and Newton admits it into his theory of natural philosophy. (See *ATOMICAL Philosophy*.) EPICURUS, in *Biography*, the founder of the system described in the preceding article, was an Athenian, of the Ægean tribe, the son of Neocles and Chærestrata, persons of honourable descent but reduced condition, and born at Gargettus in the vicinity of Athens, at the beginning of the third year of the 109th olympiad, B. C. 342. Neocles, being reduced to poverty, was sent with a colony of 2000 Athenian citizens to the island of Samos, where he occupied a small farm, and took up the profession of a school-master; and where his wife Chærestrata performed the arts of incantation and lustration, for the purpose of curing diseases and driving away spectres, in which, it is said, she was assisted by her son, Epicurus, who furnished her with lustral songs for her solemn rites. Epicurus remained at Samos and in the neighbouring island of Teos, till he was 18 years of age, and then removed, with a view to farther advantage for improvement, to Athens. Upon the death of Alexander, he left Athens, and went to his father at Colophon. Soon afterwards he removed to Mitylene, and after passing one year in that city, he resided for 4 years at Lampascus. In the 36th year of his age, he returned to Athens. From

## EPICURUS.

his 14th year to this time, he was industriously employed in the study of philosophy. At Samos he was instructed in the Platonic philosophy by Pamphilus, as Cicero informs us (*De Nat. Deor.* l. i. c. 26.), and, as we learn from Clement of Alexandria (*Strom.* l. i.); he attended in his early years upon Nausiphanes a Pythagorean, and Pyrrho the sceptic. During his abode at Athens he could not fail to derive considerable benefit from Xenocrates, who taught in the Academy, and from Theophrastus, who delivered lectures in the Lyceum. His system of philosophy, however, was the result of his own reflections, after comparing the doctrines of other sects. About the 32d year of his age, he opened a school, first at Mitylene, and afterwards at Lamplacus; but not satisfied with these obscure retreats, he determined to make his appearance on the more public theatre of Athens; and purchased for his own use, at the expence of 80 minæ, a pleasant garden, where he taught his system of philosophy. From this circumstance the Epicureans were denominated "the philosophers of the garden." During the siege of Athens by Demetrius, when Epicurus was 44 years of age, and while the city was distressed with famine, he is said to have supported himself and his friends on a small quantity of beans, which he shared equally with them. The period in which he introduced his philosophy was peculiarly favourable for his purpose: for in the room of the Socratic philosophy nothing remained but the subtlety and affectation of Stoicism, the unnatural severity of the Cynics; or the doctrine of indulgence taught and practised by the followers of Aristippus. The younger citizens were, therefore, disposed to listen to a preceptor who smoothed the stern and wrinkled brow of philosophy, and, under the notion of conducting his followers to enjoyment in the bower of tranquility, led them, unawares, into the paths of moderation and virtue. This circumstance rendered his school popular, so that disciples flocked into the garden, not only from different parts of Greece, but from Egypt and Asia. Seneca, though a Stoic philosopher, bears this testimony to Epicurus (*Ep.* 21.): "I the more freely quote the excellent maxims of Epicurus, in order to convince those who became his followers from the hope of screening their vices, that to whatever sect they attach themselves, they must live virtuously. Even at the entrance of the garden they will find this inscription: "The hospitable keeper of this mansion, where you will find pleasure the highest good, will present you liberally with barley cakes, and water from the spring. These gardens will not provoke your appetite by artificial dainties, but satisfy it with natural supplies. Will you not then be well entertained?" The disciples of Epicurus were so cordially attached to one another, that each individual cheerfully supplied the necessities of his brother. The friendship subsisting in the Epicurean fraternity is described by Cicero (*De Fin.* l. i. c. 20.) as unequalled in the history of mankind; and Valerius Maximus (*l. i. c. 8.*) relates a memorable example of indissoluble friendship between Polycrates and Hippoclidés, two philosophers of the garden. Epicurus, that he might not be interrupted in the prosecution of his studies, lived in a state of celibacy; and he exhibited an example of that temperance and continence, which he inculcated on his disciples. Towards the close of his life, however, his constitution was enfeebled, and he was afflicted with the stone. When he perceived his end approaching, he wrote a will, in which he bequeathed his garden and its appurtenances to Hermachus, and in succession to the future professors of his philosophy. On the last day of his life, he informs his friend Hermachus, that his pain was extreme: but he adds, "All this is

counterbalanced by the satisfaction of mind; which I derive from the recollection of my discourses and discoveries." He concludes with intreating his friend by the affection which he had always manifested to him and to philosophy to take care of the children of Metrodorus. The emperor Marcus Antoninus confirms this account, and further says, that Epicurus, in his sickness, relied more upon the recollection of his excellent life, than upon the aid of physicians, and instead of complaining of his pain, conversed with his friends upon those principles of philosophy which he had before maintained. At length, finding nature just exhausted, he ordered himself to be put into a warm bath, where, after refreshing himself with wine, and exhorting his friends not to forget his doctrines, he expired. His death happened in the second year of the 127th olympiad, or B. C. 271, and in the 72d year of his age. He is said to have written a greater number of original works, than any other Grecian philosopher; but none of them are extant, except a compendium of his doctrine preserved by Laertius, and some few fragments dispersed among ancient authors. His memory was held in high estimation, not only by his immediate followers, but by eminent writers, who disapproved his philosophy, but entertained a respect for his personal merit. Nevertheless his character and his philosophy have been severely censured; and the accusations against the Epicurean school have been more or less confirmed by men distinguished for their wisdom and virtue: Zeno, Cicero, Plutarch, Galen, and a long train of Christian fathers. But a candid examination of his doctrine and character will obviate many of those charges that have been alleged against them, and prove, that though in some respects this philosopher is highly censurable, in others he has been unjustly and too severely condemned. The charge of impiety admits of no refutation. The doctrine of Epicurus concerning nature not only militated against the superstitions of the Athenians, but against the agency of a supreme deity in the formation and government of the world, and he divested the Deity of some of his primary attributes. Whilst he professed the utmost contempt for popular superstitions, the gods, whose existence he allowed, were destitute of many essential characters of divinity, and his piety was of a kind very different from that which is inspired by just notions of Deity. Besides, it has been suggested, that his sentiments concerning the gods were adopted and professed for the purpose of avoiding the odium and disgrace which would have attended a direct avowal of atheism. Epicurus has also been charged with insolence and contempt towards other philosophers: but this seems to be scarcely compatible with the general air of gentleness and civility, which appears in his character. The charge of intemperance and incontinence is unquestionably an atrocious calumny. That he was eminent for the contrary virtues has been amply attested by Laertius, and also by those who were adverse to his doctrine, particularly Cicero, Plutarch, and Seneca. Epicurus has been with equal injustice represented as uneducated and an enemy to liberal science. "We ought to be thankful to nature," says this philosopher, cited by Stobæus, "for having made those things which are necessary, easy to be discovered, and those things which are difficult to be known, not necessary."

The temper and character of Epicurus were altogether the reverse of those of Zeno and the Stoics; his mode of instruction was very different; and his school was established in direct opposition to that of the Stoics; and, therefore, we need not wonder, that he should become the object of detraction and calumny. Besides, the design of his philosophy and its general principles were very different, and they endeavoured

to secure their own declining popularity by misrepresenting his principles and character, and holding him up to the public as an advocate for infamous pleasures. For these, and similar reasons, Epicurus encountered the violent opposition of the Stoics; and yet he had many friends and followers during his life, and his memory was venerated after his death. His three brothers, Neocles, Chæredamus, and Aristobulus, devoted themselves to the study of philosophy, and were supported by his liberality. Of his intimate friends the most celebrated were Metrodorus, Polyænus, and Hermachus. After his death his birth-day was celebrated by his followers as a festival; and they preferred his image in their rings or cups, or in pictures, which they either carried about their persons, or hung up in their chambers. Their reverence for his authority was such, that they committed his maxims, and some of them the whole body of his instructions, to memory; and for a long period, it was deemed a kind of impiety to innovate upon his doctrine: so that the Epicureans formed a philosophical republic, regulated by one judgment, and animated by one soul. Laertius, l. x. Brucker's Hist. Phil. by Enfield, vol. i.

EPICYCLE, formed of the Greek *επι*, upon, and *κυκλος*, circle, q. d. a circle on a circle, in the *Ancient System of Astronomy*, was a subordinate orbit, or circle, which moved on the circumference of a larger one, which latter was called the *deferent*. By means of this epicycle, one motion, apparently irregular, was resolved into two that were circular and uniform; and when the observed motion was so irregular and complicated as not to be represented by one epicycle, the method was to add others, till a nearer approximation was obtained. This system owed its origin to a prejudice that seems to have been extremely ancient, in favour of uniform and circular motion; and the problem that chiefly occupied the astronomers in those times, was to assign the proper proportion of the deferent and epicycle which should approximate nearest to the actual observations.

The representation made by this concentric theory of the solar inequalities in longitude, was as follows:

Let C (*Plate XII. Astronomy, fig. 105.*) be the centre both of the earth and of the circle F B D, and let H G K be a smaller circle, called an epicycle, whose centre B moves uniformly in the circumference F B D from west to east, or in consequentia, while the sun moves also uniformly, and with the same velocity, in the circumference of the epicycle, in antecedentia in the upper part, but in consequentia in the lower. If the point G of the epicycle, called the apogee, as being most distant from the earth, be supposed, at the beginning of the anomalistical revolution, to be placed in the point A of O F produced; and if when it comes to G the arch G H be taken similar to F B, the point H will be the place of the sun when the centre of the epicycle has moved from F to B. If then in O F, to which B H is parallel, we take O E = B H, and on E, as a centre, with the distance E A = C F, describe the circle A H P, the sun would be seen from E to move in this circle equably; for the angle A E H is equal to the angle F C B; but seen from C, the centre of the earth, he will appear to move in it inequably, for the angle A C H in the first semicircle of anomaly, that is, in the passage of the sun from A to P, is always less than A E H or F C B: and his true place H will be less advanced in longitude than his mean B. When, again, the centre of the epicycle, or the mean place of the sun, having described a semicircle of the epicycle, will be found in P, the perigee of the orbit A H P, and his mean and true places B and H, will be seen from C to coincide as they did in A, the apogee; but in the sun's passage from P to A, that is, in the second semicircle of ano-

maly, his true place H, as seen from C, will be always more advanced in longitude than his mean place B; for in this semicircle the angle P C H is always greater than P E H in D C B. The angle E H C, or B C H, which is the difference between the mean and true places of the sun, is called the equation of the orbit, as being that quantity which, added to the true motion A C H of the planet in its orbit A H P, in the first semicircle of anomaly, and subtracted from it in the opposite semicircle, will render it equal to the mean motion A E H or F C B; and it is evident that the equation, or difference, will be greatest in N or M, where the centre B of the epicycle is 90° distant from either apsis. Any lines drawn from E, the centre of the orbit A H P, to the true place of the sun in H, and from C the centre of the earth, and of the deferent F B D, to the mean place of the sun in B, are equally called the line of the mean motion of the sun, because these lines are always parallel, and mark the same point in the zodiac; and any line drawn from C to the true place of the sun is the line of the sun's true motion.

It was thus that the ancients originally proceeded in their representation of the solar inequalities, and the representation seemed to be sufficiently justified by observation; at least till the days of Tycho Brahe no observations had been made with sufficient accuracy to subject it to suspicion. Their success also, while no lunar inequality, except the simple anomalistical one, was discovered, was equal in the application of the same concentric theory to the motions of the moon; and having in two cases thus successfully, by means of one subordinate sphere, or epicycle, reconciled apparent inequality of motion with real uniformity, it was natural to suppose that other inequalities, though more various and complicated, might be explained in a similar manner, and required only the addition of other epicycles. The same method of procedure, therefore, was continued, and every new inequality which observation discovered was accounted for by a new sphere, or epicycle, producing it, till the whole number employed in the system amounted to 34. Aristotle, on narrower examination, found these insufficient, and added to them 22: but still they were deemed insufficient, and the number was at last increased to 72; but though it was not till long after the days of Aristotle that the theory was carried to such a degree of extravagance; the multiplication of epicycles rendered it, even in his time, almost as intricate and complex as the appearances which it was intended to explain. Some examples of this kind occur on the revival of it by Copernicus and Tycho Brahe; and when Hipparchus and Ptolemy introduced eccentric orbits, and by means of them somewhat diminished the multiplicity of the spheres employed by their predecessors, they were thought to do a signal service to astronomy. See *EXCENTRIC Theory*.

What was principally required in these theories was to ascertain in the one the ratio of the eccentricity; in the other, the ratio of the semi-diameter of the epicycle to the semi-diameter of the deferent. If we make the radius of Jupiter's deferent circle to that of the epicycle as 52 to 10, the epicyclical motion arising from this construction will very nearly agree with observation: only we may observe, that the oppositions which succeed each other near the constellation Virgo, are less distant from one another than those observed in the opposite part of the heavens; so that the centre of the epicycle seems to move slower in the first case than in the last. To reconcile this with the perfect uniformity of the motion of that centre in the circumference of the deferent circle, the ancient astronomers said that the earth was not exactly in the centre of the deferent, but so

placed that the equable motion of the centre of the epicycle appeared slower, because it is then more remote, and after various trials they fixed on a degree of excentricity for the deferent, which accorded better than any other with the observations, and really differed very little from them. Copernicus shews that their hypothesis for Jupiter never deviates more than half a degree from observation, if it be properly employed. They found that the epicycle moved round the deferent in  $4332\frac{1}{2}$  days, with an equation gradually increasing to near six degrees; so that if the place of the epicycle be calculated for a quarter of a revolution from the apogee, at the mean rate of  $5'$  a day, it will be found too far advanced by near ten days' motion. See Dr. Small's account of Kepler's discoveries, where this subject is treated at great length.

**EPICYCLOID**, in *Geometry*, denotes a curve generated by the revolution of a point of the periphery of a circle, along the convex or concave part of another circle.

A point of the circumference of a circle, proceeding along a plane in a right line, and at the same time revolving on its centre, describes a cycloid. And if the generating circle, in lieu of moving on a right line, moves along the circumference of another circle, whether equal or unequal, the curve described by any point in its circumference is called an epicycloid. Indeed the common cycloid has been sometimes represented as an epicycloid formed by the revolution of a finite circle on an infinite circle.

If the generating circle proceeds along the convexity of the periphery, it is called an upper, or exterior epicycloid; if along the concavity, a lower, or interior epicycloid.

In an epicycloid, the part of the circle the generating point moves along, is called the base of the epicycloid; thus in *Plate V. Analysis, fig. 9.* DC is the base of the epicycloid; V its vertex; VB its axis; DPV half of the exterior epicycloid, made by the revolution of the semicircle VLB (which is called the generant) along the convex side of the base DB; as DPU is the interior epicycloid, formed by the generant's revolving along the concave side of the base.

The length of any part of the curve, which any given point in the revolving circle has described from the time it touched the circle whereon it revolved, is to double the versed sine of half the arc which all that time touched the quietest circle, as the sum of the diameters of the circles to the semidiameter of the quietest circle; provided the revolving circle moves upon the convex side of the quietest circle; but if upon the concave side, as the difference of the diameters to the semidiameter. Otherwise: the circumference of the epicycloid GEF (*fig. 10.*) is to four times the diameter of the generating circle BE, as the sum of the diameters of the two circles is to that of the base, in the former of the cases above mentioned; but in the second, *e.g. seg.* in the same figure, as the difference, &c. In the first case, if the generating circle be supposed to have its diameter equal to half that of the base, the epicycloid FHEG is equal to 6BE. In the second case, when FI is a quarter of FG, the curve Feg will be found equal to 3FI. When the generating circle is half the base-circle, as in *fig. 11*, the epicycloid degenerates into a right line, or the diameter of the base. Hence it appears, that in order to deduce the known property of the common cycloid, or that its circumference is equal to four times the diameter of the generating circle, we need only suppose the base-circle to be infinite: an infinite, augmented or diminished by a finite quantity, being always the same.

Dr. Halley gives us a general proposition for the measuring of all cycloids and epicycloids: thus, the area of a cy-

cloid, or epicycloid, either primary, or contracted, or prolate, is to the area of the generating circle; and also the areas of the parts, generated in those curves, to the areas of analogous segments of the circle; as the sum of double the velocity of the centre, and velocity of the circular motion, to the velocity of the circular motion. The demonstration hereof, see in *Phil. Trans. N<sup>o</sup> 218*.

The areas of epicycloids may be determined by the following proportion: as the radius of the circle of the base to three times that radius together with twice that of the generating circle, so is the circular segment bH to the epicycloidal sector bHF, or the whole generating circle to the whole area of the epicycloid FEGB. As to the tangents, it is known from the time of Des Cartes, that the line Hb, drawn from any point H, to that of the base which touches the circle, whilst this point is described, is perpendicular to the curve, and consequently to the tangent. Maupertuis in discussing this subject, conceived a polygon to revolve upon another, the sides of which are respectively equal, one of the angles described a curve, the periphery of which is formed of arcs of circles, and the area is composed of circular sectors and right-lined triangles. He determined the proportion of the area and of the periphery of this figure to those of the generating polygon. He moreover supposed these polygons to become circles, the figure described to become an epicycloid; and the above-mentioned proportion, modified agreeably to this supposition, gave him the area and the periphery of the epicycloid. *Mem. de l'Acad. 1727.*

The invention of epicycloids is ascribed to M. Roemer, the celebrated Danish astronomer, during his residence at Paris, about the year 1674. These curves appeared to him to be such as best suited the teeth of wheels, constructed so as to diminish their mutual friction, and to render the action of the power more uniform; hence he was led to consider them, and to this purpose they have been applied. However, M. de la Hire in his "*Traité des Epicycloïdes*," printed in 1694, makes no mention of Roemer, and seems to claim the merit of this geometrical and mechanical invention. But M. Leibnitz, who resided at Paris in 1674 and the two following years, says, that the invention of epicycloids, and their application to mechanics, were the work of this Danish mathematician, and that he was esteemed the author of it. It does not appear that any writer published an account of epicycloids before the celebrated Newton, who, in the first book of his "*Principia*" proposed a general and very simple method of rectifying these curves. After him J. Bernouilli, during his residence at Paris, shewed how, by means of the integral and differential calculus, to determine their area, rectification, &c. Many of his "*Leçons du calcul integral*" are devoted to this object. In 1694, M. de la Hire published his "*Traité des Epicycloïdes*;" and in the "*Memoires of the Academy for 1706*" he communicated to the public an extensive and elegant treatise on these curves.

*Spherical* epicycloids are formed by a point of the revolving circle, when its plane makes an invariable angle with the plane of the circle on which it revolves. Messrs. Bernouilli, Maupertuis, Nicole, and Clairaut, have demonstrated several properties of these epicycloids, in *Hist. Acad. Sc. for 1732.*

**EPICYCLOIDS, Parabolic, Elliptic, &c.** If a parabola be made to revolve upon another equal to it, its focus will describe a right line perpendicular to the axis of the quietest parabola; the vertex of the revolving parabola will also describe the cissoid of Diocles; and any other point of it will describe some one of Newton's defective hyperbolas, having a double

a double point in the like point of the quiescent parabola. In like manner, if an ellipse revolve upon another ellipse equal and similar to it, its focus will describe a circle, whose centre is in the other focus, and consequently, the radius is equal to the axis of the ellipse; and any other point in the plane of the ellipse will describe a line of the 4th order. The same may also be said of an hyperbola, revolving upon another, equal and similar to it; for one of the foci will describe a circle, having its centre in the other focus, and the radius will be the principal axis of the hyperbola; and any other point of the hyperbola will describe a line of the 4th order. Concerning these lines, see Newton's Principia, lib. i. De la Hire's Memoires de Mathematique, &c. where he shews the nature of the epicycloid and its use in mechanics. See also Maclaurin's Geometria Organica. For the method of forming the epicycloidal teeth of wheels, see WHEEL.

EPICYEMA, from *επι*, I conceive, a word used by Hippocrates to signify a foetus, or a false conception, or mole coming on after the conception of a former or regular foetus.

EPIDAMNUS, in *Ancient Geography*, a town of Illyria, upon a small promontory between Nymphæum and Petra, built by the Corycæans. Its name, which the Romans considered as inauspicious, was afterwards changed into Dyrrhaicum, now *Durazzo*, which see.

EPIDAURIA, *Ἐπίδουρα*, in *Antiquity*, a festival celebrated by the Athenians, in honour of Esculapius. See *ÆSCULAPIUS*.

EPIDAURUS, in *Ancient Geography*, a town of Greece, in the ancient kingdom of Argos, mentioned by Homer in the enumeration of its ships, and which he represents as fertile in the production of vines. It was situated on the eastern coast of the peninsula of the Argolide, near the Saronic gulf, and opposite to the island of Ægina. This town was celebrated among the ancients for the temple of Æsculapius, situated about a mile from the river, whither the inhabitants of most parts of Europe and Asia resorted for the cure of all distempers. It is pretended that this was the birth-place of Esculapius. (See *ÆSCULAPIUS*.) Antoninus Pius, after having been adopted by Adrian, constructed in this place a temple dedicated to the deities called "Epidotes," and another dedicated to the goddess of health, to Esculapius, and to Apollo, surnamed the "Egyptian." He moreover built a house, for the accommodation of persons who inhabited the district consecrated to Esculapius, and also for lying-in women. He also re-established the portico of Cotys, which had been demolished. The grove of Esculapius near this town was enclosed by two mountains, one called "Titthion," and the other "Cynortion," upon which was constructed a temple dedicated to Apollo Maleates, and upon its summit another dedicated to Diana Coryphæa. In a rotundo near this town were preserved some curious pieces of painting, the performances of Pausias, a famous painter of Sicione, and contemporary of Apelles. The Epidaurians had a beautiful theatre in the temple of Esculapius, constructed by Polycletus, who also built the rotundo at the entrance of the town. Bacchus and Venus had also temples in this town. Epidaurus was also famous for its temple of Diana the Huntress, and a grove consecrated to her, in which was a statue of Epione, supposed to be the wife of Esculapius. In this grove was a superb fountain, splendidly ornamented. In the citadel of the town was a very beautiful statue of wood, which represented Minerva, denominated by the Epidaurians "Cissea." The temple, dedicated to Juno, was on the side of the port, on a promon-

tory which commanded a view of the sea. The Dorians, having been driven from this town by Deiphon and the Argians, united with the Ionians and with them inhabited the islands of Samos and Chios. Epidaurus is now a small place, called "Pidavra."

EPIDAURUS *Limera*, or *Epidaurus Malvesia Vecchia*, i. e. the ancient Malvoisia, is a port of Laconia, seated on the gulf of Argos, now "Golfo di Napoli," S. E. of Zarex. It is pretended that this place was founded by a colony of Epidaurians from the Argolide. Having embarked, as it is said, for the island of Cos, they were driven by contrary winds on this coast of Laconia. They were cautioned in a dream from settling here; but a serpent which they brought with them left the ship and conducted them to the land. This fable was credited in the country, and the worship of Esculapius was established along this whole coast. The Epidaurians thus contrived to obtain a considerable part of the wealth which superstition had accumulated in the Epidaurus of the Argolide; and hence the new town acquired the appellation annexed to it. It was denominated *Limera*, i. e. fished, a name which was not improperly applied to a town, the inhabitants of which contrived to exist at the charge of another. It was built upon an eminence, at the bottom of a small gulf; it was well-peopled, and was famous among other things for its excellent wine, called Malvesy or Malmesy, which grew round the vicinity of it, and with which it supplied other parts of Greece. The most remarkable objects of this place in the time of Pausanias were two temples; one of Venus, another of Esculapius, with a statue of this god. Its port was honoured with the appellation of the "Port of Jupiter Conservator."

EPIDAURUS, a town of Illyria, in Dalmatia, according to Ptolemy and Pliny, the latter of whom gives it the title of a colony; in whose time it was joined to the continent, though, as he says, it had formerly been an island. It is now "Ragusi-Vecchio."

EPIDELICUM, a town of Laconia, on the Argolic gulf, S. E. of Epidaurus.

EPIDELOS, a word used by Hippocrates for a youth in the time of his growth, from the age of seven to that of fourteen. The same author also uses it in a very different sense, expressing by it the observable days in a disease, such as the fourth, eighth, and eleventh, which indicate what sort of crisis is to be reasonably expected on the great critical day.

EPIDEMIA, *Ἐπιδημία*, in *Antiquity*, feasts of Apollo, at Delphos, and Miletus; and of Diana, at Argos.

These feasts bore the name epidemia (from *επι*, in, and *δημος*, people,) because these gods were imagined to be present on those days among the people. Accordingly, on the last day of the epidemia they sung an hymn called *αποπεμπτικός*, to bid them adieu, and set them forwards on their journey.

As those gods could not be every where, and yet were honoured in many different places, there were times allowed them to pass from one place to another, to receive the vows of their adorers. See Scaliger, Poet. lib. iii. cap. 114.

EPIDEMIA were also private festivals, and times of rejoicing, when a friend or relation had returned from a journey. Pott. Archæol. Græc. lib. ii. cap. 20. tom. i. p. 394.

EPIDEMIC DISEASES, from *επι*, and *δημος*, the people, are those diseases which prevail extensively, at different times and seasons, among the inhabitants of cities, or countries: when they occasion great mortality among the persons seized; they are termed *pestilential*.

## EPIDEMIC.

The diseases, which are liable to occur epidemically, or to attack a great number of individuals about the same time, or in rapid succession, are principally those of the acute or febrile class. Thus the plague, the sweating sickness, the yellow fever, contagious fever, or typhus, intermittent and remittent fevers, scarlet fever, small-pox, measles, dysentery, catarrh, (denominated influenza under such circumstances,) ophthalmia, hooping cough, &c. are the diseases which have at different times spread over extensive districts epidemically, some of them occasioning the most destructive mortality. Of these the influenza, or epidemic catarrh, appears to be the most extensive in the range which it takes, and the most independent of local causes: in some instances, as in the years 1781 and 1782, this disease appears to have originated in China, and thence to have spread through Asia, to Europe, and in the year following to have visited America.

The other fatal epidemics, such as the plague, yellow fever, and small-pox have been in general the calamities more particularly, though not exclusively, connected with large towns, camps, or other congregations of men. Some of these diseases, as the plague and sweating sickness, are scarcely known except as epidemical; and are altogether unknown, but as diseases of a malignant and fatal tendency: but many of the others, as small-pox, measles, scarlet fever, and typhus, are common and familiar appearances, which seldom cease to exist among us; but which, nevertheless, only occasionally assume those fearful and fatal characters, which belong to them as epidemics.

No circumstance, connected with diseases, has been the subject of more general inquiry, among the physicians of all ages, than this variation in their tendency to spread at one time to multitudes of individuals, to put on a malignant character, and to prove generally destructive; whilst at others they exist in milder forms, affecting few, and destroying scarcely any. Yet the most comprehensive views of the concomitant circumstances, in regard to the obvious conditions of the seasons, and of the moral and political state of the districts, where epidemic diseases arise or disappear, continued with the most minute observation during a succession of seasons, have failed to elucidate satisfactorily this interesting topic. Hippocrates, who has noted with accuracy the peculiarities of various years, together with the prevalent species of disease, attributes the variation of the maladies to a divine something, τὸ θεῖον; which some of his commentators consider as signifying merely the atmosphere at large; but others, among whom is Galen, suppose that he intended to express a latent and inscrutable cause in the air, which produced these surprising effects. (See Hippoc. lib. i. de Prognost. Galen in Com.—also, Sennert. lib. iv. cap. ii. de Causis Pestilentia.) Galen observes, in his commentary upon this point, “non quæcunque causas habent abditas et obscuras, divina vocamus; sed ubi admirabilia videntur duntaxat.” The modern Hippocrates, Sydenham, states, that he had observed with the utmost diligence the different peculiarities of different years, as to the obvious changes and conditions of the atmosphere, with a view to ascertain the causes of the great varieties of epidemic disorders; but that he had not made the smallest approximation to such a discovery; on the contrary, that he had remarked, that seasons of the most decided similarity, in respect to the manifest qualities of the air, were infested by diseases altogether dissimilar; and *vice versa*. “For the constitutions of different years are various;” he says, “yet they do not depend upon the degree of heat or cold, of dryness or humidity, which accompanies them; but probably originate from some occult and inexplicable changes, wrought in the bowels of the earth itself, by which the

atmosphere is contaminated with certain effluvia, which predispose the bodies of men to one or other form of disease. This predisposition continues during the prevalence of the same constitution, which, in an uncertain period of time, is superseded by another.” (Sydenham, sect. i. cap. 2. De Morbis Epidem. See also Van Swieten Comment. ad Aph. 1408.)

From a consideration of the same facts, several writers have attempted to account for these supposed occult changes in the qualities of the atmosphere, which induce epidemic diseases, by tracing them to some of the obvious phenomena of nature, by which such changes may be supposed to be effected. Thus a coincidence has been attempted to be traced between the appearance of comets and of meteors, the occurrence of earthquakes, the eruptions of volcanoes, the conjunction of certain planets, &c.; by all of which it is presumed that some important operations are accomplished in the condition of our atmosphere. Of the effects of planetary influence, indeed, in inducing or diminishing the morbid qualities of the air, nothing is to be found in the writings of the present times: the hypothesis originated and has gone by with the age of astrology. But a very late writer has filled two volumes with evidence, which he believes goes far to prove the existence and operation of some general agent, or *pestilential principle*, throughout the physical world. To this agent he ascribes the origin of earthquakes, and volcanoes, and meteors; and he seems to consider it as the medium by which comets affect the earth, producing tempestuous seasons, great heats, and great colds. (See a brief History of Epidemical and Pestilential Diseases, by Noah Webster, 1800.) This, as a mere hypothesis, would be scarcely less visionary and futile, than the supposition of planetary influence, just noticed. Mr. Webster, therefore, has collected, with great industry, an historical account of the various epidemic and pestilential visitations on record, which have successively occurred to different countries, and has connected with it a chronological view of the appearance of comets, the eruptions of volcanoes, the commotions of the earth, and of the various atmospheric phenomena, which have been described by authors in order to prove their coincidence. “It is certain,” we are told, “that comets have a very sensible effect on the weather;” (loc. cit. vol. ii. p. 122.) and Aristotle, Pliny, and Seneca, are quoted to prove that great heat, tides, and winds, are among the general concomitants of comets. “All the comets,” Mr. W. affirms, “which have approached this earth, in their passage to and from the sun, especially those which have passed very near us, have been preceded, attended and followed by most extraordinary effects, as great heat and drought in summer, and severe cold in winter; deluging rains, violent tempests, and unusual tides. They occur so uniformly, with the appearance of these bodies, and for some months preceding and following, as to leave no room to question the influence from which they proceed.” Ibid. Whatever may occasion extreme variations in the condition of the atmospheric temperature, produce inundations, dearth, &c. will thus remotely, no doubt, induce epidemic diseases, as will be shewn in the sequel. A great number of records are quoted by Mr. Webster, to prove the connection of earthquakes with epidemics (an opinion which many writers have adopted); and also to shew that sensible vapours have issued from the earth, contaminating the atmosphere, about these periods, or sometimes without any earthquakes. From these sensible exhalations an inference is readily drawn of the existence of vapours incognizable by our senses, according to the conjecture of Sydenham. It appears, however, that great pestilence, even when occurring within

## EPIDEMIC.

within a short period of earthquakes, has generally appeared before the earthquakes: nor does it occur in the seat of the earthquakes. Thus after the plague in London, in 1665, shocks are said to have been felt on the continent. But Mr. Webster does not conceive this to be any objection to the hypothesis. He believes "that pestilence and earthquakes depend on one common cause; which excites into action the internal fires." But he supposes that "the action or fermentation may precede, for months, and even years, the explosion in earthquakes and volcanoes; and by means of an insensible vapour or heat, or electrical discharges, the elements of water and air may be essentially affected in such a manner as to impair the principle of animal and vegetable life." P. 137.

This hypothesis, which was held by the ancients, (as Claudian writes,

"In cælo nunquam spectatum impune cometam,")

has been adopted by Horstius, Riverius, and echoed by several other writers on the subject of pestilence; but, like many other suppositions upon the same subject, it is altogether gratuitous, and has been received only in the absence of all positive knowledge of the real sources of pestilential diseases. The same observation applies to the supposed influence of earthquakes, and distant volcanic eruptions; more particularly, as the former are allowed to have often followed the effect ascribed to them, and the countries immediately in the vicinity of volcanoes are admitted to have been not more liable to epidemic diseases than other regions.

Two other points have been generally stated as proving the existence of a *pestilential principle*, which is diffused through the atmosphere at large: one is, that trees and vegetables are affected with mildew, and other diseases; the other, that the animal creation also often suffers, when pestilence is committing ravages among mankind. A *rubigo*, or mildew, *i. e.* "a dew impregnated with highly corrosive powers," (see Hird on Pestilence, p. 91.) was anciently deemed one of the causes of epidemic diseases. The Romans, apprised of the pernicious effects of these mildews, instituted what they denominated *Festa rubigalia*, and worshipped an imaginary god, under the name of Robigus. The appropriated sacrifice was a sucking whelp; whence Columella,

"Hinc mala rubigo, virides ne torreat herbas,  
Sanguine lactentis catuli placatur et extis."

Hoffmann mentions such a dew, "ros valde corrosivus," as having infested vegetables in 1693-4, whence the cattle died in multitudes. (Tom. i. de Temp. Ann. Infalub.) And Ramazzini ascribes an epidemic to similar dews; at which time the vegetables, corn, and fruit became black, being affected with a "lues rubigalis." (Constitut. Epidem.) The same year was remarkable for the scarcity of honey; and most creatures that live upon what they extract from vegetables died, or languished. Probably similar occurrences led many of the ancient writers to mention the silence of the grasshopper, and the drooping inactivity of the bee and the silk-worm, among the presages of impending pestilence. As to the spots, which are said to have assumed various forms, especially those of *crucicula*, or little crosses, and to have appeared suddenly on garments, utensils, &c. as they are recorded chiefly on the authority of monks, whose writings are highly tinged with superstition, they are scarcely worthy of serious consideration.

The existence of epidemic disease among cattle is necessarily much connected with the diseased condition of vegetables; and epidemics among cattle seem to have most

commonly occurred after excessive humidity. (Webster.) The calamity among brutes has sometimes proved the forerunner of pestilence among mankind; sometimes its follower; and at other times, they have raged concomitantly: but, in general, their appearance has been remote and unallied. (Hird, loc. cit.)

It is curious, again, and not easily explicable on the principle of a pestilential effluvium, unfriendly to every form of life, pervading the atmosphere, that, while vegetables droop and are mildewed, the grasshopper is silent, the bee and the silk-worm are idle, and cattle die, from its influence, swarms of insects and creatures of other species are said to be among the precursors and attendants of pestilence. It is surely an absurdity to contend for the existence of a poisonous atmosphere, destructive to the life of both animals and vegetables; and at the same time to describe the myriads of noxious insects, frogs, mice, locusts, snails, serpents, and other animals, which appear during an epidemic pestilence! Is one kind of life possessed by man and the animals useful to him, and another by those which are noxious? This contradiction in the hypothesis appears to be very general among writers. The author, whom we have already often quoted, observes, "one thing is very evident, that what I denominate a *pestilential principle* does, at certain times, pervade not only the element of air, but the water also. The proofs of this are abundantly numerous and convincing. In all the great plagues, which have afflicted the human race, other animals, as horses, cattle, sheep, sometimes cats, dogs, and fowls, together with the fish in rivers and the ocean, and even vegetables, have borne their share in the calamity. The pestilential principle has extended to every species of life. The beasts of the field perish with deadly epidemics; the fish die on the bottom of rivers and the sea, or become lean and sickly; while corn is blasted on the most fertile plains, and the fruits in gardens and orchards wither, or fail to arrive at their usual state of perfection." (Webster, Hist. of Epidemics, vol. ii. p. 153.) And immediately afterwards (p. 166.) we are called upon to "attend to the effects of a pestilential" (*i. e.* universally deleterious) "state of air, and in the production of insects and small animals. This is one of the most remarkable symptoms of a *sickly* state of the elements, &c."

It is only against such hypotheses that we have any objection. The fact, that myriads of insects have sometimes been produced, about the time when epidemics prevailed, cannot, we apprehend, be questioned; although probably many of the accounts transmitted to us on this point are much exaggerated. In some instances, such a profusion of insect life may be a result of the same cause with the epidemic, *viz.* extraordinary heat, or heat and moisture: in others, it may contribute to produce the epidemic; by destroying grain and fruits, the food of man; or grass and herbs, the food of cattle, fowls, and other animals which constitute a part of his subsistence. It proves nothing in respect to any occult quality pervading the atmosphere.

Besides, the instances of the copious generation of insects and small animals have not been universal, but partial: some particular species have been generated in profusion; and, therefore, the origin of them must be ascribed to some partial, and not to a general cause. In the plague of Lausanne, in 1613, according to Diemerbroeck, flies were produced in an incredible abundance; as well as during or preceding that of Holland, in 1635. The approach of the plague at Dantzick, in 1709, is said to have been announced by an immense number of spiders in the preceding year. The year 1633, which produced a pestilential fever among the settlers at Plymouth, in America, was remark-

## EPIDEMIC.

able for swarms of large flies, which filled the woods with their humming sounds. (Webster.) We cannot but consider, therefore, that the statement above quoted of the universal failure of animal and vegetable life, on the one hand, or the general disposition in the air to generate noxious animals, on the other, as equally erroneous, inconsistent, and absurd. How the individual species of insect or animal is generated, in such cases, or what connection the production of them may have with the pestilence, which sometimes concurs in point of time, we cannot easily ascertain. But where the means of observation fail us, gratuitous hypotheses add nothing to our knowledge.

There are, however, several circumstances which are open to our observation, which, if they do not absolutely produce epidemics of the most pestilential kind, certainly contribute to give them birth, and to aggravate them when produced, and are notoriously the source of epidemics of a less destructive species. Of these obvious causes of the origin or aggravation of epidemic diseases, some contribute directly to excite disease; others to induce, what is scarcely less necessary to their occurrence, a predisposition to them. In fact, the operation of some general agent, inducing a predisposition to be affected by contagion, or other exciting cause of disease, would appear to be the principal source of the predominance of some epidemics. For if the exciting cause never, or scarcely ever, ceases to exist, its occasional activity in inflicting disease among multitudes can only be ascribed to the casual operation of some general predisposing cause, which renders them temporarily susceptible of its influence. This is particularly exemplified with respect to contagious diseases. The contagion of small-pox, measles, and scarlet-fever perpetually exists among us; yet it is only at particular times that these diseases attack so many individuals, as to be called epidemic. In crowded towns, like this metropolis, the infection of typhous fever is perpetually generated in the close, dirty, and unwholesome habitations of the poor: yet there has been no epidemic typhus in London for seven years past. Nay, even the plague itself existed year after year in this city, without spreading generally. It must not be imagined that the disease was accidentally imported just at the periods when it raged so extensively, and with so much destruction. The principal plague-years of the seventeenth century were 1603, 1625, 1636, and 1665; in which the number of deaths from the plague, independent of those from other diseases, are reported in the bills of mortality to have been 36,269, 35,417, 10,408, and 68,596, respectively. But so far was the disease from being extinct in the intermediate periods, that from the year 1603, when the register begins, till 1667, the bills of mortality exhibit only three years entirely free from the plague. It is obvious, therefore, that the presence of infectious matter, or other exciting cause, is not alone sufficient to produce an epidemic disease. Some concurrent circumstances are likewise necessary, to give a predisposition to the human body to be readily acted upon by such cause. Now, some of these circumstances have been well ascertained, namely, particular seasons, marshy and other effluvia, a crowded and filthy population, deficient or depraved aliment, certain passions of the mind, exhaustion of the constitution by fatigue, &c. We shall illustrate the operation of each of these predisposing causes by a few observations.

1. *Seasons.*—The influence of certain seasons, in favouring the propagation of epidemic diseases, has been observed and confirmed by all the medical writers on the subject, from the days of Hippocrates downwards, and was noticed by the earliest poets, even before the time of that great physician; especially the influence of the heats of summer and

autumn, and of the sultry south winds, which blow at those seasons. In many passages of the Iliad, Homer has alluded to these causes of pestilential diseases. Thus, in book v.

“As vapours blown by Auster’s sultry breath,  
Pregnant with plagues, and shedding seeds of death,  
Beneath the rage of burning Sirius rise.” Pope, 1058.

And again in book xxiii. 37.

“Not half so dreadful rises to the sight,  
Through the thick gloom of some tempestuous night,  
Orion’s dog (the year when autumn sways),  
And o’er the feebler stars exerts his rays:  
Terrific glory! for his burning breath  
Taints the red air with fevers, plagues, and death.”

In the first book, pestilence is also ascribed to the anger of Apollo, an allegorical expression for the extreme heat of the sun. (See Pope’s version, lines 83, and 87.)

These poetic statements accord most accurately with the observations of Hippocrates, who frequently mentions epidemic fevers as common in the summer and autumn, and as prevailing most extensively when wet springs with southerly winds were succeeded by hot and close summers. A remarkable constitution of this kind, which continued for two years, is described in his treatise on Epidemics, (*De Morbis Vulgaribus*, lib. iii.) at which time ardent remitting and intermitting fevers of a bad kind prevailed, attended with fluxes, parotids, and eruptions of a pestilential nature. The autumn and spring were wet, close, and cloudy, without wind, the breezes from the south; and these continued during the hot and sultry summer, when the usual refreshing Etesian winds did not blow.

Excessive heat of the summer, without moisture, has occasionally accompanied an epidemic season. Thus in the year of Rome 325, there was a most grievous famine, occasioned by a severe drought, in all the Roman territory. “*Siccitate eo anno plurimum laboratum est; nec cœlestes modo defuerunt aquæ, sed terra quòque, ingenito humore egens, vix ad perennes subfecit amnes;*” the cattle thronged in multitudes round the arid fountains, and perished with thirst, diseases followed among the cattle, from which they were propagated by contagion among men (“*vulgarique contactu in homines morbi*”), the peasantry first suffering, then the lower classes, and at length the whole city was infected. (Tit. Liv. lib. iv. 30.) In more modern times, great droughts have been accompanied by epidemic diseases, especially in cities situated in low and damp countries. In the autumn of 1652, Bartholine informs us that a malignant fever appeared at Copenhagen, after an unusually hot and dry summer. And a similar fever raged at Leyden in the year 1669, as described by Silvius de la Boe. The spring and beginning of summer were cold, but the remainder of summer, and the autumn, were unusually hot, with little or no rain, and with a constant calm or stagnation of the air. (See Pringle on *Dis. of the Army*, p. iii. class 4.)

But epidemic diseases are still more fatal in those seasons, in the damp countries of the south, where the heats are longer and more intense, and much moisture is combined. In some parts of Italy, and in other tracts of the same latitude, epidemic fevers have appeared with such alarming symptoms, as not only to have been called pestilential, but confounded with the plague itself. In this sense we are to understand Celsus, (*De Medicina*, lib. i. cap. 10. lib. iii. cap. 8.) in the terms *pestilentia* and *febris pestilentialis*, which he describes as peculiar to the “grave anni tempus,” and the “graves regiones.” His meaning is, that this bad fever is the disease of the latter part of summer, and of autumn,

## EPIDEMIC.

when the air is thickest and most foggy, and that is most frequent in low and marshy countries. Rome was always liable to these fevers. Galen calls the *hemiritea* the epidemic of that city, and speaks of its moist air. (De Temperament. lib. ii.)

In fact the chief malignancy of the worst epidemic diseases, and of the plague itself, has always been felt in the summer and autumn; as the histories of that disease in all the large towns in Europe will testify. Diemerbroeck has justly observed, that when the plague has been excited out of its proper season, it has not spread: and Dr. Russell tells us, that in the winter time, when infected persons have come to places about Aleppo, some of whom have died in the families where they lodged, the distemper by such means was not propagated. In the four great plagues of London, during the seventeenth century, the mortality invariably increased, as the season advanced, reaching its acmè in August and September, and thenceforth gradually declining. (See the Bills of Mortality.—See also Dr. Heberden, jun. on the Increase and Decrease of Diseases, 1801.) Thus in the last plague in London, in the year 1665, the mortality of the respective months was as follows; in the spring very few persons had died of the plague, in June 590 persons died of it, in July, 4,129, in August, 19,046, in September, 26,230, in October, 14,372, in November, 3,349, and in December a few hundreds. (See PLAGUE.) The progress, in the other three instances, was exactly similar.

Again, the regular decrease of pestilential diseases, with the declining summer, equally demonstrates the necessity of the presence of the hot season for their propagation; which may operate either by rendering the contagion more virulent, by producing certain pernicious effluvia from the earth in moist places, or by inducing a predisposition in the human body to receive the influence of those exciting causes. At Grand Cairo putrid and pestilential fevers prevailed annually in March, April, and May, which the southerly winds make the hottest months in that country; but they ceased at the overflowing of the Nile, when the cold winds set in. (Prosper Alpin. de Med. Egypt, lib. i. cap. 14. Mead on the Plague, p. 30.) And “at Smyrna the annual plague constantly ceases about the 24th of July, by the dry and cold weather they always have at that time.” (Mead, p. 56.) Indeed, when this change of season takes place, while every place abounds, it must be presumed, with the contagion, yet it ceases to be detrimental. Prosper Alpinus remarks, that when this change of season comes, in the month of June, even the clothes imbued with the most pestiferous contagion then infect no one. “Sed quod valde mirabile creditur, omnia supellectilia pestifero contagio infecta tunc nullum contagii effectum in eam gentem edunt.”—And this inertness of the contagion in the most infected places, on the approach of winter, was most remarkable in the last plague of London. “Many who made most haste in retiring,” says Dr. Hodges, “made the most to return, and came into the city without fear: inasmuch, that in December they crowded back as thick as they fled: the houses, which were before full of the dead, were now again inhabited by the living; the shops, which had been most part of the year shut up, were again opened, and the people again cheerfully went about their wonted affairs of trade and employ: and even what is almost beyond belief, those citizens, who before were afraid even of their friends and relations, would, without fear, venture into the houses and rooms where infected persons had but a little before breathed their last: nay, such comforts did inspire the languishing people, and such confidence, that many went into the beds, where persons had

died, before they were even cold, or cleansed from the stench of the diseased.” (Joimologia, or Hist. Acc. of the Plague in 1665, p. 27.) In the same way we read, that when the plague was in Italy, the Neapolitans used no artifice to purify either their goods or houses; yet the disease ceased among them as entirely as in the best regulated towns. (Heberden, loc. cit.)

These facts amply prove the extensive influence of certain seasons, in favouring and interrupting the progress of the most pestilential epidemics; and that not in consequence of any occult, but of certain sensible and obvious conditions of the weather. The same circumstances of the seasons modify the propagation and diminution of the minor epidemics, such as dysentery, remittent and intermittent fevers, &c. and even the small-pox: Of the former of these, we shall more properly speak under the second head of causes; namely,

2. *Marshy and other Effluvia.*—Galen assigns two causes for pestilential fevers; the first of which is great heat of the weather, and the second, which he considers as most frequent, a corrupted state of the air, arising either from a multitude of dead bodies left unburnt, as after a battle, or from the evaporation of corrupted lakes and marshes. (De Febr. Diff. lib. i. cap. 4.) Other authors of antiquity have noticed the coincidence of epidemic fevers with marshy situations. Thus Diodorus, the historian, has recorded the occurrence of a pestilential disease among the Carthaginians at the siege of Syracuse, which he attributes to the combination of the following circumstances; the multitude of people confined within a narrow compass, the situation of the camp in a low and wet ground, and the scorching heats in the middle of the day, succeeded by cold and damp air from the marshes in the night. (Bibl. Hist. lib. xiv. cap. 70.) In more modern times the origin of epidemic diseases from marsh effluvia had been very generally observed. Fracastorius ascribes a malignant epidemic fever, in Italy, in the sixteenth century, to an extraordinary inundation of the Po, which, happening in the spring, left marshes, and those corrupting infected the air through the summer. Forestus remarks, that, from the putrefaction of the water only, the city of Delft, where he practised, was scarcely ten years free from the plague or some pestilential distemper. (Observat. lib. vi.)

The effects of marsh or putrid effluvia in giving rise to epidemic diseases have, indeed, been evinced in most of the large cities, and still more obviously in the camps of modern times. Sir John Pringle, speaking of the hot weather, during one of the campaigns in the Netherlands, in 1748, observes, that though the heats were great, yet they were the cause of little sickness, till the troops were cantoned in the marshes, where a considerable degree of putrefaction and moisture being joined, ardent, remitting, and intermitting fevers, and fluxes became general. It is remarkable that these pernicious exhalations do not rise high, nor spread far from their source, at least without such dilution as diminishes their deleterious qualities. Dr. J. Hunter has affirmed, that in the barracks at Spanish Town, in Jamaica, (which consisted of two floors, the first upon the ground, the second over the first,) the difference in health of the men on the two floors was so great as to engage the attention of the assembly of the island, and upon investigation it appeared that three were taken ill on the ground floor for one on the other. Even at a few hundred feet above the level of the marshes, the situations are extremely healthy. (Observ. on the Dis. of the Army in Jamaica, note B. p. 268, 3d edit.) The air of a marsh or of a foul camp, the same author observes, may destroy an army almost as soon as the true plague. But the remedies

## EPIDEMIC.

in such cases are obvious, and consist in getting at a proper distance from the noxious exhalations, or removing the causes of them. "A very small space frequently includes the limits of healthy and unhealthy ground." It is not now necessary to state that agues, or intermittents, originate solely from the effluvia of marshes.

Another species of effluvia, which is the source of epidemic diseases in camps and in towns, when ill constructed and neglected, arises from ground contaminated with human and other excrements, the remains of victuals, the water used in cookery, for washing, the foul straw rotting in tents, &c. Whenever a camp remains long on the same ground, especially in hot and moist weather, fluxes, and intermitting and remitting fevers, seldom fail to become epidemic, unless great precautions are used to bury all excrementitious matter, and proper receptacles and drains underground are prepared for the urine, water of cookery, &c. (See Dr. Hunter, *loc. cit.* p. 285.) In this case, however, as in that of marsh effluvia, the diseases produced will disappear, by moving the camp a few hundred yards from the foul ground.

These facts throw great light on the epidemics of large cities, which were formerly so frequent and fatal. A large town may be considered as an extensive camp, but destitute of the means of changing its situation, and, consequently, liable to be infested with the same diseases as are endemic and epidemic in camps, unless the precautions just alluded to, for the purpose of removing the sources of the pestilential effluvia, be fully adopted. And we find, accordingly, that during and previous to the 17th century, (and even later, in some countries,) the large towns were almost constantly infested, in the summer and autumnal months, with the plague, malignant, intermittent, and remittent fevers, and dysentery; the same disorders to which camps are liable. This was the condition of London during the period specified. We have already remarked, that the plague was seldom absent from the beginning of the 17th century to the year 1669, and that four dreadful visitations of that calamity occurred within the same space of time. Of the extent to which intermittent and remittent fevers prevailed, in this metropolis, we have also ample evidence. Dr. Short remarks, that early in the century, *viz.* between 1629 and 1636, "one of 40 of the whole that died of fevers, died of agues;" whereas, "now (1750) scarce one of 1100 that die of fevers die of this disease." (New Obs. Nat. Moral, &c. on Bills of Mortality, 1750, p. 208.) Burnet, in his "History of the Reformation," says, that in the last year of queen Mary's reign "intermitting fevers were so universal and contagious, that they raged like a plague." Both Sydenham and Morton have left us abundant evidence of the frequent epidemic prevalence of agues, as well as of remittent fevers, which last Morton affirms to have been extremely destructive for several years before the great plague, *viz.* from the year 1658 to 1664. He states that Oliver Cromwell died of this fever in 1658; and that his own father, himself an experienced physician, also died of it; when his whole family, the writer included, were infected. (Morton, *Pyretologia*, App. ad Exercit. ii.) Even so late as from 1720 to 1729, according to Dr. Short, "they (intermittents) and remittents afflicted the whole nation grievously."

Sometimes together, and sometimes alternating with those autumnal fevers, the dysentery was a frequent epidemic in London, in the times to which we allude, and was often attended with great fatality. For five and twenty years successively, from 1667 to 1692, the bills of mortality shew the sum of deaths under the titles of "bloody flux," and

"gripping in the guts," which must both be considered as dysentery, to have amounted every year to above 2000. During the last century, the disease has gradually declined, (Dr. Heberden on Increase and Decrease of Diff. Diseases, p. 34.) and the other fatal epidemics, just mentioned, have quite disappeared. See Annual Medical Register for 1803, vol. i. where the changes of disease in London are discussed at length.

We cannot doubt, that the present comparative healthiness, and especially the great freedom from all epidemics (the contagions of small-pox, scarlet fever, and measles excepted) which this metropolis now enjoys, is to be ascribed altogether to the measures, by which the sources of the effluvia, which excite them, have been removed, and to the general habits of cleanliness and ventilation which are at present observed by the people. These salutary measures are principally the construction of privies, drains, and common sewers; a hard and regular pavement, with a proper level for carrying off the humidity, and well cleansed by scavengers; an abundant supply of water to every part of the town, &c.

In all these points, the condition of London, like that of most other large cities in Europe, during the 17th century, was extremely defective. In the preceding centuries its condition must have been still more incommodious and filthy, so that few years elapsed without the occurrence of a considerable pestilence. We have not room, in this place, to enter more at large into a description of its circumstances; but must content ourselves with referring to the work of Dr. Heberden, *jun.* just quoted, where an abundant collection of evidence, as to the connection of those epidemics with filth and negligence in the economy of this and of other large towns, will be found. (See also the Ann. Med. Register for 1808. Maitland's and Nourthouck's History of London.) See **PLAGUE.**

It is extremely gratifying, both in a physical and moral point of view, to observe that the same means which contribute to our personal comforts, and to elevate us above the savage, *viz.* the progress of civilization and refinement, have led to banish the most loathsome and fatal distempers, to prolong life, and to diminish the prevalence and fatality of other diseases of less fatality. "While the metropolis has extended itself in all directions, and multiplied its inhabitants to an enormous amount, *i. e.* while the apparent causes of its unhealthiness have been augmented, it has actually become more favourable to health. In the year 1697, for example, the total mortality of London was 20,970; whereas, the total mortality of 1797 amounted only to 17,014: and when we take into consideration the great increase of the population of the out-parishes at the latter period, the comparative healthiness of London will appear in very strong colours." Ann. Med. Register, p. 321.

Sometimes the air of a particular district seems to have been impregnated with effluvia from putrefying animal and vegetable matter, which has occasioned an epidemic in that neighbourhood. Forestus has mentioned the putrefaction of a large fish, of the whale kind, which was left by the tide, and died, on the coast of Holland, and, during its putrefaction, infected the country with a horrid stench, in consequence of which a fatal epidemic fever broke out in the district of Egmont. (Obs. lib. vi. 9. tom. i.) The same author informs us of a pestilential fever, which raged at Venice in his time, and was produced by the corruption of a small kind of fish in that part of the Adriatic. (Ibid.) Instances are also on record of epidemic fevers occasioned by the effluvia of putrid cabbages, as well as of plants

## EPIDEMIC.

plants in marshes. (Rogers on Epidem. p. 41.) These sources of epidemics, however, are rare, and can seldom occur under a well regulated police.

3. *A crowded Population.*—From the earliest periods of time, of which we have any record, pestilential diseases were known to be the effect of crowded population, and to rage peculiarly in cities, forts, and other confined places. In the sacred writings pestilence is every where mentioned as the peculiar scourge of cities. “The sword is *without*,” says the prophet Ezekiel, chap. vii., “and the pestilence and famine *within*; he that is in the field shall die with the sword; and he that is in the *city*, famine and pestilence shall devour him.” And again, chap. xxxiii., it is said, “they that be in the *forts* and the caves shall die of the pestilence.” The city of Rome was subject to the most fatal epidemics from a very early period of its history: Athens suffered also extremely; and in modern Europe the great cities have been the common seats of plagues, from Constantinople to Moscow, and from Cadiz and Marseilles, to Copenhagen and Dantzic. (See an enumeration of the cities infected with the plague, and the dates of its occurrence, by Dr. Heberden, *loc. cit.* p. 81, *et seq.*) The same observation applies to the cities of Asia and Africa; to Aleppo, Cairo, &c. &c., as well as to those of America.

We have already stated, that the prevalence of epidemic and pestilential diseases in this metropolis was obviously connected with the existence of filth of every species, and that their gradual disappearance has been coeval with the improvements of the city, and the removal of these nuisances. The same fact is observable in all the cities of Europe: and those which, from natural or political causes, have been backward in adopting the improvements of modern times, have more lately exhibited the same effects of their negligence. The plague appeared at Copenhagen in 1764; and at Moscow so late as the year 1771. It is farther observable, that pestilential diseases generally appear first in the most crowded and uncleanly parts of towns, and rage most severely in the most crowded and dirty habitations, *i. e.* among the poor. The plague of 1665, in London, is said to have been by many persons called “the poor’s plague.” Those of 1626 and 1636 broke out at Whitechapel, a part of the town which abounded with poor, and with slaughter-houses: and that of 1665 is said to have broke out first at St. Giles’s; and there, Dr. Heberden remarks, it would probably break out again, if ever we should suffer such another calamity.

For it must be observed, that a crowded and uncleanly population contributes, in a double manner, to the origin and propagation of epidemic and pestilential diseases. It not only occasions the accumulation of every species of filth externally, from which effluvia arise to contaminate the atmosphere, in hot and moist seasons, thus producing all the diseases of camps; but it produces another species of effluvia, internally, in the habitations of men; *viz.* from the bodies of the sick, and even of the healthy, which at once generate malignant fevers, and aggravate those which arise from the other sources. (See *CONTAGION*.) So that under the circumstance of the combination of these causes, namely, when the heat and moisture of autumn generate the effluvia from external filth, and contagion is superadded from the accumulation of the corporeal effluvia, from the want of internal cleanliness and ventilation, diseases of an epidemic nature are readily excited, and are propagated extensively and fatally. Hence, before the value of these internal cautions was understood, malignant fevers so frequently occurred in hospitals and gaols, that they obtained the appellation of hospital-fever and gaol-fever. Indeed we are told

that, so late as the latter end of the 17th century, in the gaol of Newgate, a contagious fever used to break out annually, in hot weather; and that the same was true of most gaols in Europe; (The City Rembrancer, quoted by Dr. Heberden) and several facts on record, prove, how readily any acute disease is thus propagated by contagion, under these circumstances of crowded and filthy habitations; although originally, and in cleanly and airy apartments, it was incapable of spreading from one individual to another. Thus sir John Pringle observed, that, “in autumn 1757, several soldiers were brought into the hospital at Portsmouth, with a disorder compounded of the autumnal and gaol-fever; for when these men, upon being seized with the common fever of the season, were confined to the holds of the crowded transports, their distemper assumed that form. (Dis. of the Army.) So Dr. Lind has stated, that, upon admitting into an hospital one person with a flux, several other patients in the same ward have had this symptom added to their other complaints. (Lind on Fever and Infection.) And Dr. Blane has observed generally, that, supposing a ship’s company be predisposed to acute distempers, and one man or more ill of a dysentery be brought on board, this will become the prevailing disease. (On the Diseases of Seamen.)

These facts, which evince the facility with which any acute disease, or its leading symptom, is communicated from individual to individual, in a close and crowded apartment, when extreme cleanliness and ventilation are not attended to, will serve to explain several apparent anomalies in the history of several diseases, which have been stated as the result of some mysterious epidemic principle in the atmosphere. We allude to the occasional spreading of particular maladies in hospitals, in a sort of epidemic way; such as the appearance of erysipelas, connected with all slight injuries of the scalp, or other superficial parts, as related by sir William Blizard, of the London hospital, and as occurred in the surgical ward of the Royal Infirmary, at Edinburgh, many years ago; the disposition to inflammation and abscess about the perineum and neighbouring parts, mentioned by the same writer, &c. (See a Paper “On some epidemical Effects,” Med. Facts and Obs. vol. ii. 1792.) Such occurrences, we believe, are rare in proportion to the degree of cleanliness in those receptacles of the sick. We have been assured that the occurrences of this nature at Edinburgh have ceased, since a more rigid ventilation and purification have been adopted in the Royal Infirmary.

4. *Deficient and Depraved Aliment.*—The obvious causes of epidemic diseases, already mentioned, may operate both as exciting and as predisposing causes; but that to which we now direct our attention, perhaps, chiefly acts in inducing a debilitated and half-morbid condition of the body, which renders it liable to be affected by those exciting causes. Certain it is that famine and pestilence have been observed to go together, since the earliest ages of the world; and are constantly mentioned in combination, in the sacred writings; to which war is frequently added. Dearth is almost necessarily a part of the desolation of war; which, therefore, contributes to the production of pestilence indirectly by producing dearth. *Ὁ λοιμὸς μετὰ λιμοῦ*, “the plague after famine,” was an old Greek adage. Where articles of food are extremely scarce, they are often also corrupted, and may thus contribute to reduce the human constitution to a state predisposed to disease. Forestus imputes the plague at Delft, in the year 1557, to the eating of mouldy grain, which had been long kept up by the merchants in a time of scarcity. (*Loc. cit.*) And sir J. Pringle says, he had heard it observed, that in this island the dysentery is frequent among the common people, in those parts where they

## EPIDEMIC.

live mostly on grain, when the preceding crop has been damaged in a rainy season, or kept in damp granaries. (*Loc. cit.* cap. vii. p. iii.) In ancient times the corruption, as well as scarcity of food, was assigned as the cause of pestilence; as by Cæsar himself when besieging Marseilles, (*De Bello Civili*, lib. ii. 20.) "Panice enim vetere, atque hordeo corrupto, omnes (*scil.* Massilienses) alebantur; quod ad hujusmodi casus antiquitus paratum, in publicum contulerant." When we advert to the fatal epidemic disease, termed *Leu sacrè*, *Mal des ardens*, &c. by the French, and known to originate from *ergoted* rye, used as food, we shall not hesitate to ascribe considerable effects to the sort of food just mentioned. (See *Philos. Transact.* vol. lv. p. 110, and *Mem. de la Soc. Royale de Medecine*, for 1776.) Dr. Willan has observed, that the *Morbus Hungaricus*, described by Sennertus, "and some other diseases reputed pestilential, might be added to the list of epidemics, occasioned by the *ergot*; or by a similar degeneration in other grain. The sweating-sickness, which occurred more than once in England, at the beginning of the sixteenth century, was perhaps owing to some disease or depravation in wheat, &c." (*On Cutaneous Diseases*, part iv. p. 499.) It may be added, that the only epidemic occurrence of contagious fever in London for several years back, occurred after the excessively wet autumn of 1799, when corn was exceedingly damaged, and a considerable scarcity ensued.

5. *Exhaustion by Fatigue, &c.*—Besides the debility of constitution, and consequent predisposition to disease, induced by imperfect nourishment, during a famine, the exhaustion produced by excessive corporeal exertions, loss of sleep, and the depressing passions, probably contributes in no small degree to predispose the body to diseases. Thus epidemic fevers have been observed to arise after great battles. Dr. Gottward traced the origin of the plague at Dantzick to Pinow, soon after the battle of the Swedes and Saxons, in 1702. (*Ingram, Hist. of Plagues*, p. 86.) To the same cause, perhaps, we may impute the contagious fever, which raged among the troops of the late sir John Moore, on their return from the harassing campaign in Spain. (1809.) Van Swieten observes, that "strong passions of the mind, particularly terror, augment the efficacy of infection, as all writers on the plague unanimously allow," and that the same passion contributes to render the disease more fatal. If this be correct, the extensive operation of fear in besieged towns, and countries which are the seat of war, must produce considerable influence; and it cannot be doubted, that the general panic, which rapidly spreads among the inhabitants of a town, where the plague is discovered to exist, contributes materially to its propagation.

On reviewing the facts above stated, it is obvious that the sources of epidemic and pestilential diseases have been often traced to manifest circumstances, in combination with one or more of which they have generally been observed to occur: and more especially that the heats of summer and autumn appear to be absolutely necessary to the propagation of a general pestilence. The observation of Celsus, in regard to the salubrity of the different seasons, has been confirmed by those who have practised in warm climates, (*Cleghorn on diseases of Minorca*) by the physicians of camps, (*Pringle, loc. cit.* part ii. chap. i.) and by the condition of this country in the time of Sydenham. "*Saluberrimum ver est; proxime deinde ab hoc, hiems; periculosior æstas; autumnus longe periculosissimus.*" (*Celsi De Med.* lib. ii. cap. i.) But the experience of the last century, during which this order of the seasons, in point of salubrity, has been almost reversed, (for we now find July and August the most healthy months of the year, and February and

March the most productive of disease,) has thrown considerable light even on the occult principle, the *to be*, of the epidemic atmosphere. It has shewn us, what Sydenham could not have anticipated, and what to him indeed must have been incredible, that, while the seasons continue to occur, with their former vicissitudes, and while the bowels of the earth (for aught that we know) continue to send forth their vapours as usual, yet those fatal pestilential constitutions of the air no longer appear; the plague has not been seen, since the rebuilding of the city (1667); intermittents no longer infect the metropolis, and the autumnal remittents are alike almost unknown; especially since the covering of Fleet ditch, and the other improvements, made in 1766; and the dysentery, or bloody flux, now scarcely adds twenty to the annual bills of mortality! This occult principle, then; this epidemical *somewhat*, it must be inferred, neither owed its origin to the atmosphere, nor to the bowels of the earth, nor to the eruptions of *Ætna*, nor to the approach of comets. For the former of these are, doubtless, unchanged; and the latter have continued to occur at intervals as usual.

To what, then, are we to attribute the origin of those epidemic constitutions, as they have been called, of particular years, in which certain diseases extensively prevail? We have not, perhaps, a sufficiency of facts to enable us to deduce a decided conclusion; but the following inference seems to approximate to the truth, and to spring out of the facts already detailed.

The experience of camps, especially in moist seasons, teaches us how readily epidemical diseases are produced, from the contamination of the lower portion of the atmosphere with the effluvia of foul ground, and also how confined and local that contamination is, since a small elevation, or a removal to the distance of a few hundred yards, from the source of the effluvia, is sufficient to enable us to escape their noxious effects. The experience of gaols and hospitals, and other crowded and uncleanly habitations, has also demonstrated the facility with which human effluvia, accumulated about the sick, become contagious to those in their immediate vicinity; and also how readily, in this predisposed and contagious state, any acute disease, accidentally introduced, is carried from individual to individual, so as to become the prevalent or epidemic disease. Now, London, and all other crowded cities in the 17th century, combined within themselves both these peculiarities of condition, belonging as well to camps as to gaols and hospitals. The atmosphere was contaminated with the local effluvia, which rendered it pestilential externally; and, within the dwellings, especially in the poorer parts of the town, infectious atmosphere was produced, and thus whatever disease was generated, was propagated readily, and gave a character to the particular constitution of the epidemic season. How variously the epidemics must be modified, according to the various degrees and combination of the exciting and predisposing causes, must be obvious on reflection. When the bodies of the people happen to be pre-disposed to disease by want of food, or actually disordered by corrupted food, when the accumulation of filth, or the increase of marshy ground from rains or inundations, send forth miasmata in a most abundant and concentrated form, in consequence of a peculiar autumnal season, the most extensive epidemic diseases may be expected to arise. And we believe, that under such a combination of obvious circumstances, pestilence never fails to appear.

On the other hand, although a large city cannot, like a camp, be removed from the source of the pestilential effluvia, which it generates, yet industry may remove the source of these effluvia from it. And it appears to be a perfect

## EPIDEMIC.

perfect confirmation of the preceding conclusions, that, as this removal has been accomplished in London, (for example,) as the arts of peace and civilization have advanced, and wealth has introduced the disposition and the power to multiply personal comforts and conveniences; and as habits of cleanliness and ventilation have been generally diffused; in the same proportion, and with equal steps, the improvement of the general health, the absolute disappearance of the plague and the other epidemics, and the increase of longevity, are to be remarked. Hence it is only within the last few years, that the deaths have fallen short of the number of births within the bills of mortality of London.

We cannot, from our present knowledge of facts, however, account for all those modifications of diseases, nominally the same, which are observed to prevail at different seasons, and which require different modifications of the treatment. It can only be stated as highly probable, that whether the epidemic diseases originate from contagion, or human effluvia, or from the effluvia of foul ground, their degrees of violence may depend on the degrees of concentration of those effluvia; and the contagion of a mild or severe disease may tend to propagate more particularly a disease of similar character. We have already seen that peculiar symptoms, superadded to an acute disease, as affections of the lungs or of the bowels with general fever, are readily propagated along with that fever, and have modified both its character and the requisite treatment.

It has been justly observed, that "in military physic," (and the observation applies to epidemic diseases in general,) "the great improvements to be made are not so much in the cure as in the prevention of diseases, which depends altogether upon the knowledge of their causes." (Dr. John Hunter, *loc. cit.* p. 281.) Now one of the most important circumstances to ascertain, during the prevalence of an epidemic is, whether it arises from contagion, that is, from the influence of effluvia from the bodies of the diseased, or from the contamination of the air by the effluvia of foul ground, &c. For "if a disease arise from contagion, as the author just quoted remarks, "there are sure remedies against it, which are so well ascertained, that while the plague, the most contagious and the most fatal of all diseases, commits its greatest ravages in large cities, individuals remain in the midst of them in perfect security, trusting to a careful seclusion under proper regulations. (See CONTAGION.) Again, if disease arise from the air contaminated by the foul ground of a camp, or the exhalations of a marsh, it can only be avoided by a change of situation, or by taking care not to come within the sphere of activity of such noxious causes." Or in a large town, it may be added, by a strict enforcement of public and private cleanliness. But it is often extremely difficult to decide upon this point; a generally operating cause affects such a number of individuals about the same time, in the same situation, that they may seem to be infected by each other. So that, in fact, it has been disputed whether the plague itself be a contagious disease; and in regard to the dreadful epidemics of America, medical observers are by no means agreed as to their contagious origin. The contagion of the plague will be discussed hereafter. In the mean time we shall state some observations which may help to guide our decision in such cases.

By a contagious disease, is to be understood a malady in the course of which a poison is generated in the body of the sick, which produces in others a similar disease. The poison in some diseases, as the small-pox and chicken-pox, is sufficiently apparent; and the other diseases, which also arise from specific contagion, and occur but once during

life, as measles, scarlet fever, hooping-cough, &c. are well known. In others, again, as in typhus and the plague, it almost eludes our senses, and is only active when concentrated or accumulated, or close to the body of the sick. Now these contagious diseases equally affect all ages and descriptions, who suffer exposure to their cause: wherever they prevail, the old inhabitants of a country suffer as much as those that have lately arrived. But this is never the case in the yellow fever, remittent fever, or even intermittent fever, which arise from external miasmata; for such as are seasoned to the country or climate suffer infinitely less than newcomers. Again, diseases proceeding from such a cause, generally diffused, and operating upon all, do most constantly recur in the same persons as long as they remain exposed to the original cause; thus in camps and marshy situations, the sick are constantly relapsing in remittents and intermittents, till they change their situation. Dr. Hunter particularly observes, that the mortality among soldiers in the West-Indies is, in a great measure, owing to these repeated attacks. But what the same writer considers as the *experimentum crucis*, to prove the non-existence of contagion, is, when the sick leave their usual residence, and go to other places which are healthy, without spreading the disease. This constantly happens in the remittent fevers of the West-Indies; for the good effects of changing the air of the towns for that of the mountains is so well known, that it is very generally practised; but certainly without the slightest suspicion of any mischief arising from any contagion carried by the sick. If we try by this rule the fever epidemic in Philadelphia in 1793, we shall not pronounce it to be contagious. One observation more may be added: when disease arises from a cause generally diffused, separation, which in contagious diseases is commonly effectual, is here of no avail. Thus, ships of war have gone into a harbour in the West-Indies, and have had no intercourse with the people on shore, or with the crews of other ships, and yet in a few days the men have been seized with the prevailing fever in great numbers. (Hunter, *ibid.*)

With respect to the last argument but one, indeed, the inference is not perfectly conclusive; for malignant typhoid fevers, (and the plague, which is probably but an extreme degree of the same fever,) although they produce a contagion that is active and virulent in a confined and close atmosphere, nevertheless become much less contagious, in a clear and open air; so that we should expect that, on a removal of the sick to the country, the disease would assume a less virulent form. In the plague at Moscow in 1771, we are told by Dr. Mertens, that the patients, who were conveyed to the neighbouring villages, communicated the disease to the inhabitants of those places; which they would the more readily do, as probably their cleanliness was not superior to that of Moscow itself.

The specific contagions, as they have been called, as small-pox, measles, and scarlet-fever, which occur but once in the course of life, and chiefly attack children, become epidemic generally at pretty regular periods, in large towns. This may be principally explained, perhaps, by the circumstance of the necessary interval requisite for the production of subjects, who have not undergone these diseases.

On the whole, however, although the progress of refinement in the comforts of human life, during the last century, have thrown much light on the nature and origin of epidemic constitutions, in different years; it must be allowed, nevertheless, that much farther observation of facts will be requisite, in order to illustrate the subject completely.

**EPIDENDRA**, from *επι*, upon, and *δενδρον*, tree, in *Natural History*, a word used by Sir Hans Sloane, and some other authors, to express those plants which grow upon others, such as the mistletoe, which grows upon the apple-trees, &c. These are more commonly distinguished by the name of parasitical plants. See **DODDER**.

**EPIDENDRUM**, in *Botany*, so named by Hermann, Linnæus, and others, from *επι*, upon, and *δενδρον*, a tree, because most of the species, if not all, grow parasitically on the trunks or branches of trees. Linn. Gen. 464. Schreb. 606. Willd. Sp. Pl. v. 4. 114. Mart. Mill. Dict. v. 2. Juss. 66. Swartz. Act. Holm. 1800. p. 240. Tracts on Botany, 182. Schrad. Journal, 1799. 209. t. 1. Orchid. in Schr. Neues Journ. v. 1. 79. Class and order, *Gynandria Monandria*. Nat. Ord. *Orchideæ*, Linn. Juss.

Gen. Ch. reformed. Cal. three-leaved. Cor. Petals two, nearly equal to the calyx-leaves, spreading; nectary a lip, turbinate and tubular at the base, connected with the style, destitute of a spur, its termination dilated, ascending, spreading, either undivided or lobed. Stam. Anther an hemispherical, deciduous, terminal lid, of two or four cells; masses of pollen stalked, in pairs. Pist. Germen inferior, oblong or obovate, erect, furrowed; style semi-cylindrical, often gibbous, concave in front; stigma either concave or convex, in the fore-part of the style near the top. Peric. Capsule oblong or obovate, with three or six ribs, with one cell and three valves, opening by clefts between the ribs. Seeds numerous, minute, each clothed with a chaffy tunic, inserted into the downy internal ridges of the valves.

Eff. Ch. reformed. Calyx-leaves spreading. Lip tubular at the base, attached to the fore-part of the style, destitute of a spur. Anther a terminal lid, deciduous.

The original genus of *Epidendrum* in Linnæus, whose essential character is "Nectary turbinate, oblique, reflexed," comprehends many species which do not answer to that character, and which have, indeed, in several instances, been referred to this genus without a sufficient knowledge of their flowers. Hence professor Swartz has chiefly derived his genera of *Cymbidium*, *Dendrobium*, (see those articles,) *Oncidium*, *Aërides*, and *Vanilla*, so that his *Epidendrum*, whose characters we have given above, is become a much smaller, as well as a more intelligible genus, though perhaps not more natural, it having the closest possible affinity to *Cymbidium* and *Dendrobium*. The species in Swartz are 23, in Willdenow 26. Professor Martyn has, with great industry, collected 124 under the original genus. Dr. Swartz mentions 19 new ones as discovered in South America by the authors of the Flora Peruviana and Chilensis.

Among the genuine species of *Epidendrum*, as the genus stands at present, are

*E. cochleatum*, Linn. Sp. Pl. 1351. Curt. Mag. t. 572. Jacq. Ic. Rar. t. 605. Andr. Repof. t. 13. A native of Jamaica, and the first of its tribe that ever flowered in England. It is cultivated in a stove, in rotten bark, contrived so as to imitate, as much as possible, its natural situation in the clefts of aged trees, with occasional supplies of water. The bulbs are green and smooth, of a compressed oval figure, each throwing out from its base numerous thick entangled fibres, which naturally adhering to the rugged bark, strongly fix the plant and imbibe nourishment for its support. A pair of oblong, rigid, recurved leaves, entire, as in all this natural order, spring from the summit of each bulb, and between them grows a stalk, about a foot high, bearing a spike of several flowers. These are reversed, the long pale-greenish calyx and petals hanging down, while the broad, concave, somewhat cordate nectary, of a chocolate hue speckled with green, stands erect. The flower has little or no smell.

*E. fragrans*. Sw. Prod. 123. (*E. cochleatum*; Curt. Mag. t. 152.) A native also of Jamaica, flowered in the stove of Chelsea garden, under Mr. Fairbairn's care, in Feb. 1789. This has much resemblance to the foregoing, but the petals are broader, the nectary pale streaked with red, and tipped with a long point, and the flowers have a sweet smell. The stalk moreover is shorter in this species than the leaves.

*E. amabile*. Linn. Sp. Pl. 1351. (*Angræcum album majus*; Rumph. Amb. lib. xi. 99. t. 43.) Native of the East Indies. This has beautiful white blossoms, twice as large as in Rumphius's plate, on a long slender branched stalk. The lip is five-lobed, and terminates besides in a pair of very long, taper, almost capillary points. It would be a great acquisition to our stoves.

*E. nutans*. Sw. Prod. 121. A native of Jamaica, flowered in Kew gardens in March 1791. This has a leafy stem, terminated by a stalk bearing a few pale flowers, whole lip is four-lobed. They are about the size of *E. fragrans*.

*E. ciliare*. Linn. Sp. Pl. 1349. Curt. Mag. t. 463. is a beautiful and magnificent plant, native of the West Indies, which flowered at Mr. Whitley's nursery, Old Brompton, for several years before 1799. (*Curtis*.) The flowers are numerous and fragrant; their calyx-leaves and petals each near two inches long, of a yellowish buff-colour; lip white, with two elegantly fringed lobes. This species is now not very rare in the English stoves.

*E. fuscatum*. Sm. Spicil. t. 23. is rather singular than ornamental. The late Hon. Mrs. Barrington received it from Jamaica, and it blossomed in her garden in 1791. The stem is leafy, and terminates in a very long simple scaly stalk, bearing a dense corymbus of small flowers, which, like the whole plant, are of a brown purplish hue.

Several species, more or less a-kin to this last, occur in the works of Jacquin, as well as some more splendid ones with tall branching stalks, none of them yet introduced into our gardens.

**EPIDERMIS**, in *Anatomy*, is the thin insensible membrane which covers the true skin, and which constitutes, therefore, in all parts, the external surface of the body. See **SKIN**.

**EPIDERMIS**, in *Vegetable Anatomy*, from *επι*, upon, and *δερμα*, the skin, or hide, is the scarf skin, or pellicle, which covers every part of a living plant, as a similar cuticle covers the human skin. In the tender growing parts of vegetables this membrane is of the most delicate texture, pellucid and colourless, extremely thin, yet not destitute of tenacity, being wonderfully extensible on stalks, or other parts, of quick growth. Under a high magnifier it is found to be porous in a regular manner, and differently in different plants, so as to allow of the passage of fluids in a definite degree, in either direction, according to the nature of each plant. Hence some leaves perspire slowly, but imbibe moisture with great rapidity, as those of the succulent tribes; while others transmit their fluids, or imbibe external moisture, with nearly equal facility, as aquatics. Such differences are detected by experience, but scarcely discoverable by microscopical investigation.

The *Epidermis* is of the most essential importance to the life of the plant, as of the animal, protecting the living parts which it covers from the injuries of the air, while it allows of due perspiration and absorption, as well as of the action of light through its nearly colourless substance. It differs greatly in thickness according to the part of the plant to which it belongs. Exquisitely delicate on the fine organs of a flower, like the cuticle of the animal eye, it has considerably more substance on the leaf, and still more on the

branch of a tree. On old trunks it is generally obliterated or destroyed, being there no longer necessary, the dead layers of bark, (see BARK and CORTEX,) answering all the purposes of protection, while the peculiar functions of an organized porous *epidermis* are not wanted. Yet in the birch, and a few other trees, the membrane in question consists of multiplied permanent layers, like the bark, and clothes the trunk as long as that part exists. The cuticle is easily separable from young stalks in a rapid state of vegetation, and from any part of a plant by means of maceration, boiling or putrefaction, being nearly, if not absolutely, destitute of vitality, and very little subject to decomposition.

Besides the essential office of a guard to the living vegetable body against all hurtful stimulants, the *epidermis* answers many secondary purposes of protection: When naked, as usual, it proves but a feeble defence against heat or cold, but it is often covered with hair or wool, in which case it becomes a very powerful one, particularly against the too violent action of a burning sun. Flowers indeed, though peculiarly presented to all the force of this luminary, have scarcely ever any such woolly or downy defence; for the functions which they have to perform are often urgent with respect to light and heat. Many petals, notwithstanding, are silky or downy on their outside, apparently to protect them from cold, or possibly from too scorching a heat before they are full-grown, examples of which may be seen in *Convolvulus*, *Anemone*, and several other genera; but the insides of such petals are exquisitely smooth.

Examples of a very firm smooth *epidermis*, of considerable strength and thickness, may be found in the common currant, *Ribes rubrum*, the elder, *Sambucus nigra*, and the laburnum, *Cytisus Laburnum*. On the branches of the latter it acquires almost a horny hardness; but it is still more cartilaginous in the hard white tubercles sprinkled over the leaves of *Aloe perlata*, and in the teeth of the foliage of some *Saxifrage*, as well as the brittle warts of several species of *Echium* and others of the *asperifolia*. On the leaf of the white willow, and the *Protea argentea*, the cuticle has a fine silky clothing of a silvery hue; while in many more plants it is equally white, but destitute of gloss. In the leaf of many kinds of mullein, *Verbascum*, and the fruit of the peach, we find it densely covered with hairs, more or less branched. The herbage of the betony, *Betonica officinalis*, is clothed with rigid bristles, fixed upon the cuticle, which in a dry state excite sneezing. Similar hairs on the cuticle of the stinging nettle are curiously perforated, to transmit a venomous fluid lodged in bags at their base, like the poison in a serpent's tooth. Grasses, corn and horsetail, *Equisetum*, have much stony earth in their *epidermis*; while in the cork-tree, the common maple, and the Dutch elm, the same part is of a soft elastic fungous substance. The fruit of the plum, and leaves of the cabbage, have their *epidermis* covered with a fine blueish powdery resinous secretion, which will scarcely allow rain to come in contact with them, yet such plants readily absorb moisture.

Nothing can be more absurd than the idea which some philosophers have formerly entertained, that the *epidermis* was destined to give shape to a plant, and that certain lumps or excrescences on the stems of trees were originally owing to a casual wound or crack in this membrane. This opinion is easily refuted by purposely making such a wound or opening, when it will be found that no tumour can be produced by any such means; spontaneous tumours being in reality the cause, not the effect, of the bursting of the *epidermis*. S.

EPIDICASIA, *Επιδικασία*, among the Athenians. Daughters, inheriting their parents' estate, were obliged to marry their nearest relations; which gave occasion to

persons of the same family to go to law with one another, each pretending to be more nearly allied to the heirs than the rest. The suit was called *επιδικασιας δικη*; and the virgin, about whom the relations contended, *επιδικος*. Pott. Archæol. Græc. lib. 1. cap. 24. tom. i. p. 147.

EPIDIDIUM, in *Ancient Geography*, is the name which Ptolemy gave to that peninsula on the western coast of Scotland, which forms part of the county of Argyll, called Cantyre and Knapdale; and including the isles of Islay and Jura, which the Roman geographer considered as being part of it: but whether it then was integral, or not, cannot be ascertained from his account. The peninsula might at an early period have been an island; such changes has the sea made upon our surge-beat coasts: for "Dr. Smith derives this name from a similar Celtic word, signifying the isle of the Picts, who at that time were the principal inhabitants of that part of Scotland." Sir John Sinclair's Stat. Acc. vol. x. p. 519. But such a conclusion is not justifiable by the rules of Celtic derivation. *Cyn*, in that language, signifies a wedge, and *tor*, land or territory; it is, therefore, obviously derived from those two etymons conjoined, perfectly descriptive of such a tongue of land, *i. e.* a wedge-shaped territory. Mr. Baxter imagines the Pepidii, synonymous with Epidii, to have derived their name from the British word Papidiauc, which signifies any thing shaped like a flute or pipe, as was the peninsula of Cantyre, the country of the Pepidii. From the southern point, called the mull of Cantyre, promontorium Epidium, the coast of Ireland may be plainly seen; it being only 16 miles to the south foreland in Coleraine.

EPIDIDYMIS, in *Anatomy*, a part of the testicle, situated behind the body of that organ, and consisting of its excretory duct in a wonderfully convoluted form. It ends in a straight tube, called the vas deferens. See TESTIS.

EPIDO'SIS, from *επιιδωμι*, to increase, in *Surgery*, a preternatural enlargement of parts.

EPIDOT. See STRAHLSTEIN.

EPIDOTES, from *επιιδωμι*, I cause to grow, in *Mythology*, deities which were supposed to preside over the growth of infants.

EPIDROME, from *επι*, upon, and *δρομη*, to run, in *Surgery*, an afflux of fluids, or, as they were formerly phrased, humours, especially when it arose from the application of a ligature round any part.

EPIDROMUS, of *επι* and *δρομη*, course, in the *Ancient Shipping*, a sail near the stern, which was the largest but one in the ship.

EPIECIA, in *Ancient Geography*, a town of Greece, towards the sea, and not far from Corinth; N. of Tenæa.

EPIEZ, in *Geography*, a town of France, in the department of the Loiret, and district of Beaugency; 12 miles E. of Orleans.

EPIGÆA, in *Botany*, from *επι*, upon, and *γαια*, the earth, expressive of the prostrate growth of this humble shrub. Linn. Gen. 219. Schreb. 295. Willd. Sp. Pl. v. 2. 615. Mart. Mill. Dict. v. 2. Juss. 161. Clafs and order, *Decandria Monogynia*. Nat. Ord. *Bicornes*, Linn. *Erica*, Juss.

Gen. Ch. *Cal.* Perianths double, close together, permanent; the outer of three ovato-lanceolate, pointed leaves, of which the external one is larger than the rest; inner in five deep, upright, lanceolate, pointed segments, somewhat longer than the outer. *Cor.* of one petal, salver-shaped; tube rather longer than the calyx, hairy within; limb spreading, in five deep ovate-oblong lobes. *Stam.* Filaments ten, thread-shaped, the length of the tube, and inserted into its base; anthers oblong, acute. *Pist.* Germen globose,

globose, with five furrows, downy; style cylindrical, as long as the stamens; stigma obtuse, in five lobes. *Peric.* Capsule nearly globular, depressed, with five angles, five cells, and five valves. *Seeds* numerous, roundish. *Receptacle* large, separating into five parts.

*Ess. Ch.* Outer calyx of three leaves; inner in five deep segments. Corolla salver-shaped. Capsule of five cells, with a central five-parted receptacle bearing the seeds.

The species are two.

1. *E. repens.* Linn. Sp. Pl. 565. Swartz Prod. 74. Andr. Repof. t. 102. Lamarck Illustr. t. 367. f. 1. "Leaves ovate, inclining to heart-shaped, entire. Tube of the corolla cylindrical." Native of pine forests in Virginia and Canada, but, like many plants of a cold or alpine climate, difficult to preserve in our gardens. It flowers in April or May. The root throws out many woody, procumbent, creeping, branched, hairy, leafy stems, which form wide-spreading patches. Leaves alternate, on hairy foot-stalks, ovate, obtuse, entire, heart-shaped at the base, veiny, shining, but roughish to the touch. *Stipulas* none. *Flowers* in terminal, dense, bracted clusters, fragrant, of a pale blush-colour, each about the size of a small cowslip. It is increased by parting the roots, thrives in a light sandy loam, but requires the shelter of a long-continued deep snow, or some equivalent protection, to survive our winters. We saw it in great perfection at Messis. Lee and Kennedy's nursery, Hammer-smith, in 1797.

2. *E. cordifolia.* Swartz Prod. 73. Lamarck Illustr. t. 367. f. 2. "Leaves heart-shaped, roundish, serrated, convex, hispid, rigid. Tube of the corolla ovate." Native of boggy places on the highest mountains of Guadeloupe and Cayenne. Smaller than the former, with pointed and more hispid leaves, whose foot-stalks are very short. *Flowers* in like manner terminal, but with a more inflated tube. The young shoots are very hairy.

**EPIGÆA**, in *Gardening*, comprehends a plant of the low, trailing, shrubby, flowering kind. This is the creeping epigæa, or trailing arbutus (*E. repens*).

*Method of Culture.*—This is readily effected in this plant by the trailing stalks, which soon put out roots at the joints, and may then be cut off from the old or parent plants, and be set out in a shady situation, where the soil is moist, in the autumnal season, that the plants may be well established before the spring. In cases where the winter proves severe, it may be necessary to lay a few dried leaves, or other light covering over them, to protect them from frost; but after they become well rooted, they seldom require more than being kept clean from weeds.

These are ornamental plants in the fronts of the borders of shrubberies.

**EPIGASTRIC ARTERY**, in *Surgery*. The proper mode of operating in certain cases of ruptures, so as not to run any risk of wounding this vessel, will be explained in the article **HERNIA**.

**EPIGASTRIC REGION**, in *Anatomy*, one of those portions, into which the cavity of the abdomen is divided by anatomists in their descriptions. "The epigastric region," says Winflow, "begins immediately under the appendix ensiformis at a small superficial depression, called the pit of the stomach, and in adult subjects ends above the navel at a transverse line, supposed to be drawn between the last false ribs on each side.

"This region is subdivided into three parts, one middle, named epigastrium, and two lateral, termed hypochondria. The epigastrium takes in all that space which lies between the false ribs of both sides, and the hypochondria are the spaces covered by the false ribs." Sect. 7. § 79, and 80.

**EPIGASTRIUM.** See **EPIGASTRIC**.

**EPIGINOMENA**, of *επιγινόμενα*, *I supervene*, in *Medicine*, are new symptoms which occur in the progress of a disease. See **EPIPHENOMENA**.

**EPIGLOTTIS**, in *Anatomy*, is a small and thin piece of cartilage, placed at the back of the tongue, and having the office of closing the glottis, or opening of communication between the larynx and pharynx, when the food is passing into the latter cavity from the mouth. The anatomical description of this part will be found in the article **LARYNX**; its offices are described in that of **DEGLUTITION**.

**EPIGONIUM**, *επιγονιον*, a musical instrument among the ancients, with forty strings, so called from its inventor Epigonius, a native of Ambracia, a city of Epirus. Mem. Acad. Inscript. vol. v. p. 167.

**EPIGONIUS**, in *Biography*, was a mathematician of Sicyon, and a native of Ambracia, who is celebrated by the ancients for the invention of an instrument of forty strings, which was called after his name, Epigonium. When he lived is uncertain, but as it was in times of simplicity, we may suppose that these strings did not form a scale of forty different sounds, but that they were either tuned in unisons and octaves to each other, or accommodated to different modes and genera. The 12 semi-tones of our three-stopt harpsichords included thirty-six different strings.

The Greeks were divided into numerous sects of musical speculators, before and after the time of Aristoxenus: as the Epigonians, Damonians, Eratoclians, Agenorians, and many others enumerated by Porphyry, in his Commentary on the Harmonics of Ptolemy. Of these, however, all we know is, that they differed; it is, perhaps, little to be lamented, that we no longer know about what.

Music has many obligations to Epigonius. He was the first who played on stringed instruments without a *plestrum*. And, according to Athenæus, he first united the melody of flutes to that of the citharas; and by this means softened the harshness and inflexibility of the citharas when played alone. He invented the chromatic genus, and was the original author of choruses.

**EPIGRAM**, in *Poetry*, a short poem, or composition in verse, treating only of one thing, and ending with some point, or lively ingenious thought.

The word is formed of *επιγραμματα*, *inscription*, of *επιγραψω*, *to inscribe*, or *write upon*.

Epigrams then, originally, signify *inscriptions*, and they derive their origin from those inscriptions placed by the ancients on their tombs, statues, temples, triumphal arches, &c. See **INSCRIPTION**.

These, at first, were only simple monograms: afterwards increasing their length, they made them in verse, to be the more easily retained: Herodotus, and others, have transmitted to us several of them.

Such little poems retained the name of epigrams, even after the design of their first institution was varied, and people began to use them for the relation of little facts and accidents, the characterising of persons, &c.

The Greeks confine their epigrams to a very narrow compass; for though, in the Anthology, we here and there meet with a very long one; yet, ordinarily, they do not exceed six, or, at most, eight verses. The Latins were not always so scrupulous, and the moderns much less, as to these bounds.

M. le Brun, in the preface to his "Epigrams," defines an epigram a little poem, susceptible of all kinds of subjects, and ending with a lively, just, and unexpected thought; which are three qualifications essential to the epigram; particularly

ticularly the first and last of them, *viz.* brevity, and the point or close of the epigram.

To attain brevity, only one thing is to be aimed at in the poem, and that to be pursued in the concise terms possible. Authors are much divided as to the length the epigram is to be confined to; the ordinary limits are from two to twenty verses; though we have instances, both among the ancients and moderns, where they extend to fifty. But still it is allowed, that the shorter the better, and more perfect, as it partakes more of the nature and character of this kind of poem. The point or turn is a quality much insisted on by the critics, who require the epigram constantly to close with something poignant and unexpected, to which all the rest of the composition is only preparatory. Others there are, who exclude the point, and require the thought to be equally diffused throughout the whole poem, without laying the whole stress on the close: the former is usually Martial's practice, and the latter that of Catullus. Which is the most beautiful and perfect manner is disputed by a third class of critics.

The Greek epigrams have scarce any thing of the point or briskness of the Latin ones: those collected in the Anthology have most of them a remarkable air of ease and simplicity, attended with something just and witty; such as we find in a sensible peasant, or a child that has wit. They have nothing that bites, but something that tickles. Though they want the salt of Martial, yet, to a good taste, they are not insipid; except a few of them, which are quite flat and spiritless. However, the general faintness, and delicacy of the pleasantry in them, has given occasion for a Greek epigram, or "epigram à la Greque," to denote, among the French, an epigram void of salt or sharpness.

It is principally the point that characterizes the epigram, and distinguishes it from the madrigal. See POINT.

In the modern versification, as observed by F. Mourgues, the epigram and madrigal are distinguished by the number of verses and the close. 1. By the number of verses, which in the modern epigram does not go beyond eight, nor in the modern madrigal comes short of six; and, 2. In that the close, or period, of the epigram, has always something more lively and studied than that of the madrigal.

The epigram is the lowest, and least considerable of all the productions of poetry; and it is in general rather an effect of good luck, than of art, to succeed therein. The finesse, and subtilty, of the epigram, M. Boileau observes, should turn on the words rather than the thought; which seems very little to the credit of this kind of composition, as it reduces it to the nature of the pun, or equivoque. F. Bouhours confirms the hint, in adding that the equivoque is what usually shines the most in the epigram.

One great beauty of the epigram is, to leave something for the reader to guess, or supply. Nothing pleases the mind so much, as to find something in itself in the objects presented it; nor does any thing disgust it more than to preclude it from shewing and exercising a faculty it values itself for. Segrais.

The epigram admits of great variety of subjects: some are made to praise, and others to satirize, which last are much the easiest; ill-nature serving instead of point and wit. Boileau's epigrams are all satires on one or another. Those of Des Reaux are all made in honour of his friends; and those of Mad. Scudery are so many eulogues. The epigram being only a single thought, it would be ridiculous to express it in a greater number of verses; it must have its unity

like the drama. The comedy has an action for its subject, and the epigram a thought.

We might select a number of excellent epigrams in our own language, if our limits allowed of enlarging this article. We shall content ourselves with subjoining the following. The first is that of Mr. Pope, said to be written on a glass with the earl of Chesterfield's diamond pencil.

"Accept a miracle, instead of wit,  
See two dull lines by Stanhope's pencil writ."

The next is an epigram, expressed concisely and closing beautifully, which was written on the leaves of a fan by Dr. Atterbury, late bishop of Rochester:

"Flavia the least and slightest toy  
Can with resistless art employ.  
This fan in meaner hands would prove  
An engine of small force in love;  
Yet she with graceful air and mien,  
Not to be told or safely seen,  
Directs its wanton motion so,  
That it wounds more than Cupid's bow.  
Gives coolness to the matchless dame,  
To every other breast a flame."

Mr. Prior lashed the impertinence of a bad writer, who had taken the liberty of censuring him, in the following epigram:

"While faster than his costly brain indites,  
Philo's quick hand in flowing letters writes.  
His case appears to me like honest Teague's,  
When he was run away with by his legs:  
Phoclus, give Philo o'er himself command;  
Quicken his senses, or refrain his hand.  
Let him be kept from paper, pen, and ink,  
So he may cease to write, and learn to think."

The following epigram was written by Mr. Wesley, on occasion of erecting a monument to Mr. Butler, author of Hudibras, in Westminster Abbey:

"While Butler, needy wretch, was yet alive,  
No generous patron, would a dinner give.  
See him, when starv'd to death, and turn'd to dust,  
Presented with a monumental bust!  
The poet's fate is here in emblem shown,  
He ask'd for bread, and he receiv'd a *stone*."  
See BUTLER.

EPIGRAPHE, *Ἐπιγραφή*, *Superscription*, an inscription on a building, to signify its use, occasion, the time when, and the person by whom it was built.

EPIGRAPHERS, *Ἐπιγραφεύς*, among the Athenians, officers that rated all those of whom taxes and contributions were required, according to every man's ability, kept the public accounts, and prosecuted such as were behind-hand with their contributions. Potter. Archæol. Græc. lib. i. cap. 14. tom. i. p. 81.

EPILA, in *Geography*, a town of Spain, in the province of Arragon, on the Xiloca; 17 miles W. of Saragossa.

EPILEPSY, in *Medicine*, *ἑπιληψία*, and *ἑπιληψίς*, signifying *sudden seizure*, is a disease which consists of convulsions of the greater part of the muscles of voluntary motion, attended with a loss of sense and feeling, and ending in a state of insensibility, and seeming sleep.

This disease has received a variety of denominations, especially among the ancient writers. By the early Greeks it was called the  *sacred disease*, from a notion of its origin in supernatural

## EPILEPSY.

supernatural influence; some of the exorcists and impostors of those times even pretended to decide, from variations in the symptoms, whether the fits were occasioned by Cybele, Neptune, Mars, or some of the heroes. Hippocrates seems to have been the first who combated these absurd notions of his countrymen; and severely reprehends the impostures of the exorcists, in pretending to set aside what more than human power had inflicted, by incantations, magic ceremonies, and sometimes by the most contemptible juggling. (See Hippoc. de *Morbo Sacro*.) Aretæus, however, remarks that it might have the denomination of *sacred* on other accounts; either from its magnitude, every thing great being deemed sacred; or because it could not be removed by human means, but only by divine power; or from the opinion that a *dæmon* had entered into the patient, or for all these reasons together. (De *Causis Affect.* lib. i. See also Cæl. Aurelian. De *Morb. Chron.* lib. i. cap. iv.) In like manner the Romans call every thing remarkable and great "sacred:" "*sacra anchora*," "*aurei sacra fames*," &c. (Van Swieten. § 1071.) Upon the same ground epilepsy has been called *morbus Herculeus*, the Herculean disease. By the Romans, it was sometimes termed *morbus comitalis*, "the assembly disease;" either because epileptic persons were more frequently observed to be seized in a crowd of people, or because the public meetings, called *comitia*, were adjourned if any one happened to be attacked with an epileptic fit. It has likewise been termed *morbus caducus*, or "falling sickness," because the patients, when they are seized with the paroxysm, fall down.

The leading features and principal circumstances of the epileptic convulsions are nearly the same in all the different persons whom the disease affects. The disease consists of fits, which attack suddenly often those who are seemingly in perfect health, and, after lasting for some time, pass off, and leave the persons again in their usual state.

The individual attacked loses suddenly all sense and power of directing his muscular actions; so that, if standing or sitting, he falls immediately, or perhaps with convulsions is thrown to the ground. In that situation he is agitated with violent convulsive actions, variously moving his limbs and the trunk of his body, with a force that is altogether preternatural. Commonly the limbs on one side of the body are more violently agitated than those upon the other. In all cases the muscles of the face and eyes are much affected, exhibiting various and violent distortions of the countenance. The tongue is often affected, and thrust out of the mouth, while the muscles of the lower jaw are also affected, and, shutting the mouth with violence, often wound the tongue grievously. While these convulsions continue, the face becomes red, then livid and swelled, from the interruption to the circulation through the head, and there is commonly at the same time a frothy moisture issuing from the mouth; and in the most severe cases the urine and alvine excrements are involuntarily discharged. In some instances a hissing or stertorous noise is emitted. The convulsions have for a few moments some remissions, but are suddenly again renewed with great violence. Generally, after no long time, this terrible struggle ceases altogether, and the patient remains for some time without motion, in a state of absolute insensibility, and under the appearance of a profound sleep. After some continuance of this seeming sleep, he sometimes suddenly, but for the most part by degrees only, recovers his senses and power of motion, but without any memory of what had passed from the first seizure of the fit, and complaining of head-ache, and excessive pain in all the limbs as if from severe fatigue. During the convulsions the pulse and respiration are hurried and irre-

gular; but, when the convulsions cease, they return to their usual regularity and healthy state.

In most cases the attack of epilepsy comes on suddenly, without any warning symptom: but sometimes it is preceded by certain sensations for a few moments previous to its actual commencement. Of these the most remarkable is that, which has been termed the *Aura epileptica*; which is a sensation of something moving in some part of the limbs or trunk of the body, and from thence creeping upwards to the head; and when it arrives there, the person is immediately deprived of sense, and falls into an epileptic fit. This feeling is described sometimes as resembling that of a cold vapour, sometimes as like a fluid gliding, and sometimes like the sensation of a small insect creeping along the body; and very often the patients can give no other distinct idea of their sensation, than as in general of something moving along. It might be supposed that this sensation arose from some affection of the extremity or other part of a nerve, acted upon by some irritating cause; and that the sensation, therefore, followed the course of such a nerve. But it is not found to follow the course of any nerve distinctly, and it generally seems to pass along the integuments. There are occasionally also other symptoms immediately preceding the fit, and generally referred to the head, where no *aura* is perceived. In some persons a giddiness comes on; in others a spark of light, which increased to a bright beam, usually ushers in the paroxysm; depending probably on the sudden turgescence of the vessels in the head, which produces pressure on the optic nerve, and occasions this depraved sensation. Dr. Gregory used to mention in his lectures, at the college of Edinburgh, the case of an officer, who had a more singular perversion of sight, previous to the fit of epilepsy; he always fancied that he saw an apparition of an old woman, with a blue cloak, holding a staff in her hand, with which she knocked him down. He also mentioned an instance of visual deprivation which occurred to Dr. Fothergill; a young lady, whom the Dr. was attending as an epileptic patient, remarked that he was covered with spangles, (the more unusual as an ornament to a quaker's coat,) and immediately she fell down in a fit.

Under the article *CONVULSIONS* we have entered into a detail of the circumstances which conduce to their origin and production; and as the whole of those observations apply to the epileptic convulsions most particularly, it will not be here necessary to repeat them. We have there stated that convulsions occur under two opposite conditions of the body, *viz.* of *repletion* and *inanition*; or, in the language of Dr. Cullen, of *excitement* and *collapse* (First Lines, § 1286.): and that various *irritations* in different parts of the body, but especially in the head, give rise to them in different instances.

Sauvages has described a great variety of species of epilepsy, which he has distinguished chiefly according to the causes which produced them. Dr. Cullen has mentioned only three species, which (as to the utility of division with a view to the curative indications) might be reduced to two. His first species is *epilepsia cerebialis* (from *cerebrum*, the brain), which attacks suddenly, without any evident cause, or preceding sensation, except perhaps a giddiness or deprivation of sight; and includes the *plethoric* epilepsy and *eclampsia* of Sauvages, as well as his *cachectic* epilepsy. The second species, is *E. sympathica*, in which the *aura epileptica*, before described, precedes the attack; a circumstance which is scarcely of sufficient importance to designate a species. The third, *E. occasionalis*, includes those instances of epilepsy which originate from manifest and accidental irritation, and which subside when the irri-

tation

## EPILEPSY.

tation is removed. These various causes of irritation are, wounds, or blows of the head, from falls, and other external injuries; pain in various degrees, as from parturition, dentition, worms in the alimentary canal; indigested food, or other substances in the stomach, as narcotic poisons, spirituous liquors, &c; passions of the mind, especially fear; and a variety of other sources of disturbance to the system, as the eruption of small-pox, and other febrile irritations, the venereal orgasm, intense study, the suppression of customary discharges, &c.; and, lastly, the imitative propensity, which is particularly conspicuous in women and children, as illustrated at large under the head of CONVULSIONS.

We have there stated the impossibility of explaining the proximate cause of convulsive diseases, in consequence of our ignorance of the nature of the nervous power, or of the connection between the action of the muscles and the brain, or the faculty of volition, in a state of health. And it were sufficient to mention the attempts to reason upon the subject, which the ablest physicians have made, in order to prove their futility. The learned Boerhaave says, (*Aph.* 1086.) "Et patet quidem, causam proximam omnium epilepsiarum exquisitam esse nimiam cerebri in nervos motorios, nullam in sentientes, actionem." "It is obvious that the proximate cause of every perfect epilepsy is always too great an action of the brain upon the nerves of motion, and too little upon those of sense:" which is only stating the fact in other words; for it amounts merely to this: "in every true epilepsy the motions of the body are violent, and the sense is lost: the proximate cause is still as obscure as before." Dr. Cullen scarcely pretends to form a theory upon the subject. "I might say," he observes, "that it is an affection of the energy of the brain, which, ordinarily under the direction of the will, is here, without any concurrence of it, impelled by preternatural causes. But I could go no further: for as to what is the mechanical condition of the brain, in the ordinary exertions of the will, I have no distinct knowledge; and therefore must be also ignorant of the preternatural state of the same energy of the brain under the irregular motions here produced." (*First Lines*, § 1284.) The indications of cure therefore cannot be formed from a knowledge of the proximate cause of the disease; but we obtain some useful intimations for the treatment, by diligently attending to the various remote causes; both those which induce a predisposition, and those which occasionally excite the disease. Our principal object, then, will be to avoid the occasional causes, and to remove or correct the predisponent.

The predisposition to epilepsy, in the majority of instances, seems to consist partly in what may be termed a morbid irritability, or mobility, of constitution, in which the action of slight irritations (which are applied to most persons with impunity) excites great commotion in the nervous system; and partly in a turgescence of the vessels of the head, which accompanies a general plethora. This appears from the circumstances, that plethoric persons are very frequently the subjects of epilepsy; that it is often brought on by causes inducing any unusual turgescence of the blood-vessels; and that it has been frequently cured by diminishing the plethoric state of the body, more frequently, we believe, than by any other system of practice. This principle was inculcated by Dr. Cullen, and is strenuously adopted by the present Dr. Gregory, his successor. It was likewise maintained by the late Dr. Fothergill, who has left us the following excellent remarks on this point of practice.

After stating that many epilepsies occurred to him, which eluded all his endeavours to relieve them by means of the medicines ordinarily recommended as specifics, and which

therefore suggested the necessity of adopting some other mode of procedure, he says, "I had observed that fits were most liable to return in the plenitude of health; that epileptics were often extremely incautious in respect to diet; that children, highly indulged, were liable to the disease; that in every other period of juvenescence, and in middle aged adults, if they were at all subject to the disease, it was when they had either committed some excesses, or, by one means or another, were plethoric; and that, in habits subject to epilepsy, the disease seldom recurred, without either an habitual indulgence in eating, or a neglect of necessary exercise. This induced me to recommend, in many cases, a total abstinence from all animal food, and from all fermented liquors. Care was taken to regulate the secretions, and such a course of medicine prescribed, as might seem expedient to induce the patients, or their friends, scrupulously to comply with such a course of diet. It was in vain to restrict the quantity of animal food. There are few who have, at all times, resolution enough to submit to the first intimations of satiety. It was, therefore, necessary to enjoin such a kind of diet, as was accompanied with but slender provocations to excess, and which, at the same time, would afford the least quantity of nutriment; by which that fullness, which, in many epileptic cases, appears to be a stimulus sufficient to produce the spasms, would be avoided, and the parts, which were the immediate seat of irritation, might gradually recover a degree of strength and firmness, that would be proof against every slight impression.

"It often happens in diseases, that a proper plan of diet is of much more importance in the cure than any thing we are acquainted with in the *Materia Medica*: it is, however, of not less necessity to engage the patients and their friends in a steady perseverance of the method we direct. The generality of people have very little notion that diet can do more than merely support their strength; that it can be made subservient to the cure of their diseases, they cannot easily be brought to comprehend, &c.

"In young boys, I apprehend, the epilepsy most generally proceeds from their own craving appetites, and the neglect of those who are about them. It may not be improbable, but in such cases worms may also have a share in producing the fits. Be this as it may, anthelmintics, however powerful, seldom cure the disease; they may abate occasionally the frequency, or the violence of the attacks, but they too often, at the same time, bring on a greater degree of irritability, and at length, if repeated frequently, and in considerable doses, seldom fail of confirming the disease. Moderate laxatives, with a light chalybeate interposed, and steadily continued, with a course of diet, consisting of milk, vegetables, fruit, and things prepared from them, and in moderate quantities, seldom fail of removing the disease in such habits. Riding and bathing in cold water, and the usual means of establishing good health, must, at the same time, be attended to, and the plan pursued with patience; for it is not to be expected in diseases that affect the nervous system, the most remote and finest part of the economy, when once they have debilitated, or otherwise disordered, these very feeling parts, and their influence is become habitual, that after-medicines, however active, penetrating, and efficacious, can, in a very short time, restore the ability to perform their functions as they ought to do." (See *Medical Obs. and Inquiries*, vol. vi. p. 72.)

This plan of light and moderate living, with occasional laxatives, should be adopted in every case of epilepsy, where it does not arise from loss of blood, or other causes of inanition, or is not connected with a cachectic or emaciated habit: and even in the last case, the plan is often useful, especially

## EPILEPSY.

cially where a morbid change, such as exostosis, suppuration, or tumour of any kind, is going on in the head.

It might be supposed that artificial evacuations, especially blood-letting, would be the most effectual means of diminishing the plethoric state of the system: and such it certainly proves, when the plethora has become considerable; and if it threatens immediate disease, this evacuation ought to be made to the quantity that the urgency of the symptoms seems to require. It is, however, a matter of old observation, that blood-letting is not the proper mode of preventing the recurrence of the plethoric state; but, on the contrary, that it is often the means of favouring it, especially when the operation is performed at regular periods. There is, however, a case of epilepsy, as Dr. Cullen remarks, in which there is a periodical or occasional recurrence of the fullness and turgescence of the sanguiferous system, giving occasion to a recurrence of the disease. In such cases, when the means of preventing plethora have been neglected, or may have proved ineffectual, it is absolutely necessary for the practitioner to watch the returns of these turgescences, and to obviate their effects by the only certain means of doing it, that is, by a large blood-letting. When the general plethora is not great, but the symptoms indicate considerable local turgescence in the head, the application of cupping-glasses, after scarification of the neck, or the use of a seton, blister, or issue, near the same part, will afford the means of some relief, by the evacuations which they produce. An open issue, indeed, in distant parts, as in the arm, has been found useful in some instances of epilepsy, by tending to obviate the plethoric state, or, as Dr. Cullen suggests, by determining occasional turgescences to those parts, and, therefore, diverting them, in some measure, from their action upon the brain.

Epilepsy, however, as we have already stated, is also the result of a state of debility, with which the excessive nervous mobility that is easily excited to convulsions is, in many other instances, observed to be connected; especially in hysteria, in the condition of infancy, &c. Where this debility has been the consequence of inanition, as from loss of blood, from previous disease, and so forth, a nourishing generous diet will be requisite to restore the strength; and instances are occasionally seen, in which the propriety and success of this practice are manifest. Where there is obviously a feeble state of body, with pale complexion, and without any appearances of local plethora, the propriety of being much in the open air, of using the cold bath frequently, and of regular exercise, adapted to the strength and habits of the patient, must be equally evident. He may still farther contribute to remove debility, and its consequences, especially that great mobility which is a principal part of the predisposition to epilepsy, by the use of tonic and antispasmodic medicines.

By a sort of routine, too generally pursued by indiscriminating practitioners, remedies of the last mentioned classes are most commonly given in epileptic cases, more particularly of late the metallic tonics, while the diet and regimen are not sufficiently attended to. However, as the circumstances of the constitution occasionally favour their operation, it cannot be doubted that the disease has, in many instances, been removed by these means; and numerous cases are on record, in which particular species of tonic remedies have effected the cure of epilepsy. The preparations of iron have been most commonly employed for this purpose, as the rubigo ferri, or the sulphat of iron, or its combination with ammonia (ferrum ammoniacale); and cures have been said to be accomplished by all these preparations. Dr. Cullen, however, observes, that he never found them effectual;

which he attributes partly to their not having been always employed in the proper circumstances of the disease, and partly to the inadequate quantities in which they have been given. (First Lines, § 1335.) A preparation of copper, the cuprum ammoniacum of the Edinburgh Dispensatory, has been one of the most celebrated of the metallic tonics, and Dr. Cullen admits it to have been often successful. It should be given in the dose of one grain at first, twice in the day, and gradually increased to as much as the stomach will bear. Zinc, especially in the form of flowers of zinc, (as the oxide was formerly denominated,) has been much extolled for its virtues in the cure of epilepsy, and other spasmodic diseases, when it was used in small doses. Much larger quantities of it, however, have been administered lately, and its character of efficacy has been considerably diminished. The sulphat of zinc, or white vitriol, appears to be a more efficacious tonic. Arsenic has more recently been introduced as a remedy for epilepsy. The safety and great powers of this metal, as a medicine, especially in the cure of periodical disorders, such as intermittent fevers, megrim, or intermittent head-ache, &c. have been fully established, and afford an analogy in its favour. A writer on this subject, in the Edin. Med. and Surg. Journal (for July 1809) states, that he has found arsenic successful in the cure of epilepsy, when it "occurred in young subjects, principally anterior to the age of puberty, and of what is termed a delicate make, and feeble stamina, especially when the disease assumes, or very nearly approaches, a periodic form. The drunken epileptic likewise, when not of a full plethoric habit, has found a cure from the firm and judicious use of this potent remedy, due attention having been paid to the alvine evacuations." There is still another tonic of the metallic class, which has lately been recommended as an efficacious remedy for epilepsy, the nitrat of silver (or lunar caustic), and is said to have cured the disease, when it had already been of many years standing. (See two cases of this nature, Med. and Phys. Journal, vol. i. p. 184. vol. ii. p. 70.) A quarter of a grain of this active substance, given three times a day, is a sufficient dose for an adult in the beginning; it may be afterwards carefully increased.

The vegetable tonics are admitted to possess less efficacy in alleviating this dreadful disorder. Among these the bitters have chiefly been employed, and the cinchona is the most active. Like the arsenic, it is especially adapted to those epilepsies which recur at certain periods, and which are not at the same time accompanied with any plethoric state, or turgescence of the blood: in such periodical cases, if the bark is employed some time before the expected recurrence, it may be useful; but it must be given in large quantity, and as near to the time of the expected recurrence as possible. The leaves of the orange tree have sometimes proved useful in this disease, probably by the bitter quality which they possess.

But this caution must again be given, with respect to the employment of any of the above-mentioned tonics in this disease, that in all cases where it depends upon constant or occasional plethoric state of the system, these medicines are likely to be at least ineffectual; and if sufficient evacuations be not made at the same time, they are likely to be very hurtful. The various success with which such remedies have been administered is, doubtless, to be ascribed partly to inattention to these circumstances; although it is equally clear, that many epilepsies, connected with organic lesion in the head, or a connate disorder of the habit, are beyond the power of any medicine.

With a view of diminishing the tendency to the convulsions of epilepsy, various antispasmodic medicines have been employed,

employed, such as valerian, castor, musk, the foetid gums, empyreumatic oils, and other substances of strong and offensive odour. But, although these remedies were generally administered at one period, and were much extolled for their antispasmodic powers, they seem to have lost their high character, in a great measure, and are much less employed than heretofore.

Several remedies have also been introduced, as *specifics*, in the disease in question; *i. e.* as remedies which possessed a peculiar influence over it, independently of any sensible quality or operation. Such are the viscous quercinus, or mistletoe, the cardamine pratensis, agaricus muscarius, &c. Experience has not sanctioned the recommendation of these medicines, which appear to be nearly inert. If the mistletoe were ever beneficial, it was probably in those times when it was an object of religious superstition, and operated through the medium of an impression on the mind. On the same principle, taking remedies that excited horror may have sometimes succeeded in curing the disease; such as the powder of human skulls, (*pulvis cranix*,) &c. A pamphlet has been published lately, however, in which the specific efficacy of the mistletoe is again contended for by Dr. H. Frazer. But the cases, there related, are mentioned so briefly and uncircumstantially, that no just inference as to the means of cure can be deduced; and the weight of negative evidence is, on the other hand, so great, that we are disposed to attach little credit to the mistletoe. We have employed it, since the publication of the pamphlet alluded to; but without any effect.

Dr. Fothergill, whose experience and sound observation led him to infer, that plethora was the most frequent cause of curable epilepsies, and the system of diet and evacuation, before mentioned, the most effectual means of cure, was disposed to attribute the reputed efficacy of all the last-named remedies for epilepsy to a very different operation, than was intended by the prescriber: namely, to their impeding digestion, and consequently preventing incurring plethora. "Valerian," he says, "castor, the foetid gums, empyreumatic oils, and, if there be any thing still more disgusting, commonly make a part of the medicines proposed for this disease. There are some others, whose qualities, indeed, are not quite so repugnant to our taste and smell, such as the mistletoe, and the *flores cardamines*; but to balance this difference, it is requisite to take these such a length of time, and in such quantities, as make them not less disgusting at length. May not, therefore, both these kinds of medicines, and most of those made use of as specifics from ancient authority, now and then confirmed with instances of benefit, derive the greatest part of their consequence from their quantity, or their disgusting qualities, which, by lessening the appetite, allow nature to recover herself, and shake off a disease, which indulgence principally produced." (*Med. Obs. and Inquir. vol. vi. p. 77.*)

The sight of others in a fit of epilepsy is the most common of the mental irritations which produce epilepsy: this, therefore, should be guarded against, especially among children, and more particularly in a family where epilepsy has already appeared. The famous cases of epilepsy, thus communicated among the orphans at the hospital at Haerlem, are well known; (*see CONVULSIONS*,) as well as Boerhaave's successful cure, by threatening a severe punishment (burning with a hot iron) to the first who should be seized with a fit. This counter-impression upon the mind, which Dr. Cullen whimsically terms the *tonic* of fear, was sufficient to obviate the effects of the other. (*See KAUU Boerhaave impetum faciens, § 4:6.*)

Some anti-epileptic powers have been attributed to opium,

hyoscyamus, or henbane, digitalis, and some other sedative medicines; but it is obvious that these substances can only be serviceable in those cases where the disease depends upon irritation, or increased irritability, when their effects will be temporary; and that, when there is any plethoric or inflammatory condition present, they must, with the exception of digitalis, prove hurtful, especially opium.

With respect to the fit itself nothing can be done, in general, except restraining the patient from injuring himself. He should be removed from the ground, or from the vicinity of any hard body, against which he might be bruised by the convulsive motions of the limbs; and in those cases in which the tongue is apt to be protruded, and lacerated by the teeth, a sort of gag should be introduced. In very plethoric habits, where the determination of blood to the head is very great, it may be advisable to open a vein during the fit, in order to obviate the immediate danger of life, from a rupture of the vessels of the brain.

When the fit is preceded by an *aura*, as before mentioned, which has been supposed to arise from irritation propagated along the course of some particular nerve, various means of preventing the fit have been suggested; such as destroying the part, in which the *aura epileptica* arises, by means of the knife or caustic, applying a blister, or making an issue in it, or cutting the branch of the nerve along which the *aura* seems to pass, or lastly, applying a ligature upon the limb, above the part from which the *aura* arises. A tourniquet has been recommended for the last purpose, to be worn loose upon the limb, and tightened the instant that the *aura* is perceived; by which means the epilepsy has been said to have been prevented in several instances.

On dissection after death from epilepsy, a variety of morbid and preternatural appearances have been in the head, to which the symptoms might be justly attributed, in consequence of the mechanical irritation of the brain. Thus irregularity in the arrangement of the bones, or some other malformation of the cranium, inequalities or protuberances on its interior surface, splinters, or depression of the bones from fracture; tumours, thickening, and ossification in the membranes enveloping the brain; fluids of various acrimony effused, or collected within the brain, or on its surface, and tumours formed in the substance of the brain; have in various instances been discovered after epilepsy had proved fatal.

EPILESMON, from ἐπιληδω, *I cause to forget*, a term used by the old writers in *Medicine*, to express a loss of memory.

EPILOBIUM, in *Botany*, a name adopted by Conrad Gesner, and explained by him as indicative of the character of this genus, ἐπι λοβω ων, *a violet*, or beautiful flower, growing upon a pod; in which he is followed by Dillenius and Linnæus. See Bauhin's *Pinax* 245, sect. 7; *Dill. Plantæ Agri Giffensis*, 132; and *Linn. Phil. Bot.* 176. Willow-herb.—*Linn. Gen.* 188. *Schreb.* 251. *Willd. Sp. Pl. v. 2.* 313. *Sm. Fl. Brit.* 409. *Mart. Mill. Dict. v. 2.* *Juss.* 319. *Geortu. t. 31.* (*Chamænerion*; *Tourn. t. 157.*) Class and order, *Oëandria Monogynia*. Nat. Ord. *CalycantHEME*, *Linn. Onagrea*, *Juss.*

*Gen. Ch.* *Cal.* Perianth superior, of one leaf, deeply four-cleft; segments oblong, pointed, coloured, deciduous. *Cor.* Petals four, roundish, broadest upward, cloven, spreading, inserted into the calyx between its segments. *Stam.* Filaments eight, awl-shaped, alternately shorter; anthers oval, compressed, obtuse. *Pist.* Germen inferior, cylindrical, very long; style thread-shaped; stigma thick, obtuse, either undivided or four-cleft, the lobes revolute, downy. *Peric.* Capsule very long, cylindrical, with four furrows,

four cells, and four valves, with a longitudinal linear partition originating from the centre of each. *Recept.* columnar, square, its angles attached to the partitions, which at length separate from it. *Seeds* numerous, oblong, crowned with down, and affixed in two rows to each angle of the receptacle.

*Eff. Ch.* Calyx in four deep segments. Petals four. Capsule oblong, inferior. Seeds feathered.

An elegant genus of plants, with flowers of a paler or deeper rose-colour, natives of watery or boggy situations, chiefly in the cooler or mountainous parts of Europe. The roots in all are perennial, and often creeping. *Leaves* undivided. *Flowers* spiked or racemose, terminal. *Stamens* in some direct, in others declining.

The species in Willdenow are twelve, to which are to be added *E. roseum*, Schreb. *Lipf.* 147. *Sm. Fl. Brit.* 411. *Engl. Bot. t.* 693, and *E. alpinifolium*, Villars *Dauph. v.* 3. 511. *Engl. Bot. t.* 2000, both by him made varieties of *E. montanum*. The British species therefore, at present ascertained, are nine.

*E. angustifolium*, Linn. *Sp. Pl.* 493. *Curt. Lond. fasc.* 2. t. 24. *Engl. Bot. t.* 1947, called the French or Persian Willow, or Rosebay Willow-herb, is one of the most handsome, though most common, of the whole. It rarely with us occurs wild, but thrives and blossoms abundantly in any garden, whether the situation be moist or dry, even in almost any part of London. Linnæus says, *Fl. Lapp. n.* 146, "it frequently, like a garden, surrounds the hut of the wild Laplander, who vies with Diogenes in the simplicity of his household furniture, but whose habitation seems the palace of a divinity, when this stately plant is in bloom." This is an instance, among many, of a truly alpine plant succeeding well in the smoke of a city, while others require the purest air possible.

**EPILOGUE, EPILOGUS**, in *Oratory*, &c. The peroration, or last part of a discourse, or treatise; containing ordinarily a recapitulation of the principal matters delivered.

The word is Greek, ἐπιλογεῖς, formed of the verb ἐπιλάβε, *I say after*; the epilogue being the end, or conclusion of a discourse.

**EPILOGUE**, in *Dramatic Poetry*, is a speech addressed to the audience, when the play is over, by one of the principal persons or actors in the piece; containing usually some reflections on certain incidents in the play, particularly those of the part of the person who speaks it.

In the modern tragedy, the epilogue has usually somewhat of pleasantry in it; intended, perhaps, to compose the passions raised in the course of the representation, and send the audience away in good humour; though how far that design is good and laudable will bear some dispute: an ingenious author in the *Spectator* compares it to a merry jig on the organ, after a good sermon, to obliterate any impressions that might have been made thereby, and send the people away just as they came.

In effect, though the epilogue, in this sense, may seem an abuse, yet has it the countenance of antiquity; the Romans had something of the same nature, though under another name. Their exodium was a kind of farce, brought on the stage when the tragedy was over: "ut quicquid lacrymarum ac tristitiæ cepissent ex tragicis affectibus, hujus spectaculi risu detergeret," says the scholiast of Juvenal. The epilogue is but of modern date, much later than the prologue. Many, indeed, have taken the exodium of the ancient Greek drama for an epilogue, because Aristotle defines it to be a part rehearsed after the chorus had sung for the last time; but in reality, it was of a quite different nature. The exodium was the last of the four parts of the

tragedy: containing the unravelling and catastrophe of the plot, and answering to our last, or fifth act.

**EPIMEDIUM**, in *Botany*, as at present understood, is certainly different from the ἐπιμηδίου of Dioscorides, which seems to be *Osmunda Lunaria*, though his description does not exactly agree even with that plant. The derivation of the name has always appeared obscure. Ambrosini deduces it "from ἐπιμύω, to close, or shut up, because the leaves conceal the flowers; or from ἐπιμύδα, because of its growing frequently in Media." Neither of these is satisfactory, and the word seems rather to have a reference to the plant μύδιον, a *Campanula*, or something very near that genus, which immediately precedes it in Dioscorides. However this may be, the name *Epimedium* is now universally applied to the Barren-wort. *Linn. Gen.* 59. *Schreb.* 79. *Willd. Sp. Pl. v.* 1. 660. *Sm. Fl. Brit.* 187. *Prod. Fl. Græc.* 103. *Mart. Mill. Dict. v.* 2. *Juss.* 287. *Tourn. t.* 117. Class and order, *Tetrandria Monogynia*. Nat. Ord. *Corydalis*, Linn. *Berberides*, Juss.

*Gen. Ch.* Cal. Perianth inferior, of four ovate, obtuse, concave, small, spreading, deciduous leaves, placed directly under the petals. *Cor.* Petals four, ovate, obtuse, concave, equal, spreading. Nectaries four, pouch-shaped, blunt at the base, the size of the petals and lying upon them, fixed to the receptacle by the edge of their orifice. *Stam.* Filaments four, awl-shaped, pressed close to the style; anthers oblong, erect, of two cells and two valves, the latter separating from their base upwards, leaving the partition free. *Pist.* Germen superior, oblong; style shorter than the germen, as long as the stamens; stigma simple. *Peric.* Pod oblong, pointed, of one cell and two valves. *Seeds* numerous, oblong.

*Eff. Ch.* Petals four. Nectaries four, pouches lying on the petals. Calyx opposite to the petals, caducous. Pod superior, of one cell, with many seeds.

*E. alpinum*, Linn. *Sp. Pl.* 271. *Engl. Bot. t.* 438. *Fl. Græc. ined. t.* 150. *Ger. em.* 480. The only species, a native of shady mountainous places in several parts of Europe, not very difficult of cultivation in our gardens, flowering in May. The root is perennial, creeping, slender, blackish. *Stems* upright, simple, about a foot high, round, smooth, bearing one large, twice or thrice compound leaf, divided irregularly in a three-fold order, and composed of large, pendent, tremulous, thin, delicate, heart-shaped, pointed, finely ciliated, smooth leaflets, glaucous beneath; and one upright panicle, alternately branched, whose stalks are red, and rough with glandular hairs. *Flowers* singular and elegant, drooping, with dark red petals, and yellow pellucid nectaries. Dr. Smith, in his *English Botany*, suggests that "perhaps what is called the stem ought to be reckoned only the foot-stalk of the leaf, which, as in *Turnera*, bears the flower-stalk."

**EPIMENIDES**, in *Biography*, a Cretan philosopher and poet, who was contemporary with Solon, and of whom many fables are related. Among others it is said, that, being sent by his father in search of a straying sheep, he slept in a cave, where he reposed himself for 50 years, and when he awoke, found to his surprise, that he was become an old man, that every thing about him was become new and strange. It is also recorded of him, that he could dismiss the soul from his body, and recal it at pleasure; and that he had familiar intercourse with the gods, and possessed the gift of prophecy. Most of these fictions may probably have originated with the Cretans, who were, to a proverb, famous for their powers of invention. (*Titus, i.* 12.) The more credible account of Epimenides is, that he was a man of superior talents, who pretended to intercourse with the

the gods, and in order to justify his pretensions, lived in retirement upon the spontaneous productions of the earth, and practised various arts of imposture. At the time of his pretended inspiration he might, possibly, have the art of appearing totally insensible and entranced, which would be considered by ignorant and deluded spectators as a power of dismissing and recalling his spirit. Such was his reputation for sanctity, and for the performance of religious rites, that, during a plague in Attica, which happened in the 46th olympiad, about 596 years B.C., the Athenians sent for him to perform a sacred lustration; in consequence of which, as it is said, the gods were appeased and the plague ceased. Of this ceremony we have given a particular account under the article ALTAR. On occasion of this visit to Athens, Epimenides became acquainted with Solon, the Athenian legislator, who is said to have disapproved the conduct of the Athenians in this instance of superstition; and yet availed himself of the advice of the philosopher in compiling his celebrated code. The Athenians, however, were delivered from the pestilence, and were disposed liberally to requite Epimenides for his services. The philosopher declined accepting their offered recompence, and contented himself with a branch of the sacred olive, which grew in their citadel, and with this he returned to his native country, after having concluded a league between the Gnoſſians of Crete and the Athenians. Soon after his return to Crete he died, as Laertius says, at the age of 157 years, or, as the Cretans pretend, at the age of 299 years. The superstitious Cretans paid him divine honours after his decease; and he has been reckoned by some the 7th wise man of Greece, to the exclusion of Periander from this number. Laertius enumerates a variety of pieces written by Epimenides, both in prose and verse. Among the former was a treatise "On Sacrifices," and "An Account of the Cretan Republic;" and among the latter "The Genealogy and Theogony of the Curetes and Corybantes," in 5000 verses; "Of the Building of the ship Argo, and Jason's Expedition to Colchis," in 6500 verses; "Of Minos and Rhadamanthus," in 4000 verses; and a treatise "Of Oracles and Responses," mentioned by St. Jerome, from which St. Paul is said to have taken the quotation in his epistle to Titus, ch. i. 12. Laert. l. i. c. 10. Brucker's Hist. Phil. by Enfield, vol. i.

EPIMETRON, ἐπι and μέτρον, *measure*, in *Antiquity*, an allowance given the tax-gatherers in the Roman provinces, over and above the just quantity of wine or grain they were obliged to furnish. The epimetron, or over-measure, in different provinces, was different, being always greater in those that were remote, than in the nearer provinces. The different kinds of things wherein it was given made likewise a difference in the quantity allowed. The reason of allowing an epimetron, or over-measure, was to make good the leakage of the wine and waste of grain, that would necessarily happen by transporting it to Rome.

The provinces whose taxes were converted into money, and paid in specie, were free from epimetron.

EPIMORIOS, Ἐπιμοριος, *superparticular*, of μέτρον, *I divide*, an epithet given by Galen to certain differences in the pulses with respect to their inequality as to the time of their beating. All times, rythms, or modulations of the pulse, according to number, consist, he observes, of equal or unequal proportions. Of equal, when the time of the distension is equal to that of contraction; and of unequal, when the one of these exceeds the other; and this inequality may be from certain or uncertain excesses. The certain excesses may be either in multiple proportion, or as number to number, which is the epimorion.

EPIMULIS, ἐπι, upon, and μύλη, *whirl* done on the top of the knee, a name given, by some anatomists, to the patella, or knee-pan.

EPIMYLIA, in the *Ancient Music*. We are told, in Athenæus, that the epimylia, and the song called "Hymæus," were the same (see ΗΥΜÆΥΣ): Athenæus adds, that it is probable that the word epimylia comes from ἐμύλη, which in Dorian signifies sometimes the return, and sometimes the augmentation and surplus of nourishment given to those who labour at the mill. But perhaps after all, this word comes from μύλα, a mill.

EPIMYTHION, Ἐπιμυθιον, in *Rhetoric*. See TABLE.

EPINA, or HARPINA, in *Ancient Geography*, a town of Triphylia, upon the river Parthenia, N. of Phryga.

EPINAC, in *Geography*, a small town of France, in the department of Saône and Loire, chief place of a canton in the district of Autun, with a population of 1128 individuals. The canton contains 11 communes and 5802 inhabitants, on a territorial extent of 155 kilometres.

EPINAL, or ESPINAL, a town of France, in the department of the Vosges, chief place of the district of the same name, with a population of 7321 individuals. It is situated on the river Moselle, 12 miles N.W. of Remiremont, and 480 miles of Paris, and 42 miles S.E. of Nancy. N. lat. 48° 22'. The canton has a territorial extent of 297½ kilometres, 19 communes, and 14,709 inhabitants.

As chief place of a district, Epinal has a sub-prefect, a ranger, a brigadier-general, who commands in the department, a captain of the national gendarmerie, two courts of justice, and a register office. It has several paper-mills. The soil produces wheat, rye, oats, hemp, and flax. Its principal trade is with hemp and flax, hemp and flax seed, oil, and the produce of a few manufactures of linen and cotton stuffs, and writing paper. The whole district comprises five cantons, 116 communes, and 62,592 inhabitants, on a territorial extent of 1285 kilometres.

EPINAY, a small town of France, in the department of l'Ille and Vilaine; three miles W. of Vitré, which, before the revolution of 1789, conferred the title of marquis on the lord of the manor.

EPINENEUCOS, from νευω, *I nod*, in the old writers of *Medicine*, a word used to denote a sort of unequal pulse, beating differently in the different parts of the same artery; as when it rises strongly against the two middle fingers of the physician who feels it, and weaker at the extremes; this sort of pulse is described by Galen as common to hectic patients, and is called also perineneucos.

EPINEPHELOS, of ἐπι and νεφελον, *clouds*, in the *Writings of the Ancient Physicians*, a term used to express the cloudy matter seen floating in the urine in fevers, &c. See ENOPREMA.

EPINETTE, *Fr.* in *Music*. See SPINET.

EPINEU le Chevreuil, in *Geography*, a town of France, in the department of the Sarthe and district of Sillé; 12 miles W. of Le Mans.

EPINEUL, a town of France, in the department of the Yonne, and district of Tonnerre; 1½ mile N. of Tonnerre.

EPINEUX des Lombes, in *Anatomy*, a name given by Winslow, and some other of the French authors, to certain small muscles of the loins, not mentioned by the old anatomists; but called by Albinus interspinales lumborum.

EPINICINION, Ἐπινοικιον, in the *Ancient Music*, a song of victory, by which the Greeks celebrated the triumph of conquerors.

EPINICION, Ἐπινοικιον, from ἐπι, on, νικη, *victory*, in

the *Greek and Latin Poetry*, denotes, 1. A feast, ceremony, or rejoicing, on occasion of a victory obtained. 2. A poem or composition, on the same subject. Scaliger treats expressly of the epinicion in the *Poetics*, lib. i. cap. 44.

EPINOI, in *Geography*, a small town of France, in the department of the North; 9 miles S. of Lille, and 9 miles N. of Douai.

EPINYCTIS, (from *επι*, and *νύξ*, night,) in *Surgery*, a kind of pustule, of the nature of the furunculus, originating in the night-time; or, according to *Ætius* and *Paulus*, attended at this period with the most pain.

EPIODIUM, in the *Ancient Music*, a funeral song or dirge with the Greeks; called *Mænia* by the Romans.

EPIPACTIS, in *Botany*; according to *Hederic*, from *επιπυκνωσις*, or *επιπυκνωσ*, to congeal, or to grow together at the summit. In this sense the name may very well apply to the *Helleborine* of some authors, for which *Haller* and *Swartz* retain it, and which has always been taken for the *επιπυκνωσις* of *Dioscorides*, whose account of the matter is too short and vague to afford much light. The petals of this plant do indeed approach each other, towards the upper part, more than in many of the *Orchideæ*, and such an explanation is more correct than that of *Ambroini*, who derives the word from *παγος*, ice, or *πυκνωσις*, frozen, "because the herb grows in very cold places, as it were upon or above the ice," which circumstance by no means applies to it. *Haller* in *Aët. Helvet.* v. 4. 100. *Hist. Stirp. Helvet.* v. 2. 147. *Swartz. Aët. Holm.* 1800. p. 231. t. 3. f. N. *Traacts on Botany*, 159. *Schrad. Neues Journ.* v. 1. 62. *Willd. Sp. Pl.* v. 4. 83. (*Helleborine*; *Tourn.* t. 249. *Serapias*; *Linn. Gen.* 462. *Schreb.* 503. *Juss.* 65. *Gærtn.* t. 14.) *Class and order, Gynandria Monandria. Nat. Ord. Orchideæ.*

Gen. Ch. reformed. *Cal.* three-leaved; leaflets direct, a little spreading, concave, acute. *Cor.* Petals two, rather smaller than the calyx, slightly spreading. *Nectary* a lip proceeding from the lower part of the style, tapering, or concave, or keeled, at the base, usually longer than the calyx, deflexed, entire or cloven, concave or flattish, often furrowed above. *Stam.* Anther an hemispherical, moveable, permanent, terminal lid, of two cells, attached by its posterior edge to the top of the style; masses of pollen oblong, powdery, granulated, sometimes lobed. *Pist.* *Germen* inferior, obovate, erect, furrowed, sometimes twisted; style erect, roundish, notched at the top; stigma in front, oblique, under the anther. *Peric.* Capsule inferior, oval, with six ribs and one cell, opening by clefts between the ribs. *Seeds* numerous, minute, tunicate.

Ess. Ch. reformed. *Calyx-leaves* direct, slightly spreading. *Lip* without a spur. *Anther* a terminal permanent lid. *Pollen* powdery, granulated.

*Swartz* and *Willdenow* enumerate fourteen species of this genus, eight or nine of which are British. They are divided into two sections, eight of them having an undivided lip, and six a cloven one. The former are,

1. *E. latifolia.* (*Serapias latifolia*; *Linn. Syst. Veg.* ed. 14. 814. *Sm. Fl. Brit.* 942. *Engl. Bot.* t. 269.) A native of cool, shady, rather mountainous woods, throughout Europe. The roots are perennial and creeping. *Stems* simple, about two feet high, leafy, roughish. *Leaves* ovate, or broad-lanceolate, ribbed and plaited, clasping the stem alternately. *Flowers* in a long terminal spike, with bractees at least as long as the germen, the lower ones longer than the whole flower. *Calyx* and *petals* of a brownish green. *Nectary* shorter than either, heart-shaped in front, purplish, acute,

2. *E. palustris.* (*Serapias palustris*; *Scop. Carn.* v. 2. 204. *Lightf.* 527. *Sm. Fl. Brit.* 943. *Engl. Bot.* t. 270.) An elegant native of watery, boggy meadows, in England and other parts of Europe, flowering in July and August. The flowers are fewer, but larger and more specious than the last, being variegated with white, purple and yellow, and the lip is crenate. *Linnaeus* has called this *S. longifolia*, but very incorrectly, and from mistake.

3. *E. microphylla.* *Sw.* (*Serapias parvifolia*; *Ehrh. Herb.* 120.) A native of Germany and Switzerland; possibly also of England, as we have some suspicion of its being the *Helleborine altera*, *atrorubente flore*, of *Ray's Synopsis*, 383. It most resembles the first species, but has much smaller leaves.

4. *E. grandiflora.* (*E. pallens*; *Sw. Serapias grandiflora*; *Sm. Fl. Brit.* 944. *Engl. Bot.* t. 271.) Frequent in the beech woods of Berkshire and other midland counties of England, flowering in June. The flowers are few, closed, large and elegant, white with yellow lines upon the lip. *Leaves* elliptical.

5. *E. ensifolia.* *Willd.* (*Serapias ensifolia*; *Sm. Fl. Brit.* 945. *Engl. Bot.* t. 494. *S. xiphophyllum*; *Linn. Suppl.* 404.) Confounded by *Haller*, *Hudson* and others with the last, from which it differs in its minute bractees, narrower and longer leaves, shorter lip, and more slender germen. It grows in Switzerland, and very rarely in the mountainous parts of Yorkshire and Worcestershire.

6. *E. rubra.* (*Serapias rubra*; *Linn. Syst. Veg.* ed. 14. 816. *Sm. Fl. Brit.* 946. *Engl. Bot.* t. 437.) Native of shady mountainous woods in several parts of Europe, rare in England. It is distinguished by its elegant rose-coloured flowers, whose lip is marked with yellow wavy ridges, and auricled at its base.

7, 8. *E. erecta* and *falcata*, natives of Japan, are the only remaining species of this section; and these, as *Willdenow* observes, appearing to have a spur to the flower, are perhaps species of *Limodorum*.

The species in *Swartz* and *Willdenow* with a cloven lip are,

9. *E. Nidus avis.* (*Ophrys Nidus avis*; *Linn. Sp. Pl.* 1339. *Sm. Fl. Brit.* 931. *Engl. Bot.* t. 48.) A parasitical plant, growing in shady beech woods, chiefly on a chalky soil, and singular for its uniform pale brown hue. The root consists of numerous clustered juicy fibres. *Leaves* none, except small scales on the stem. *Flowers* numerous, forming a dense spike, inodorous, with a cloven divaricated lip.

10. *E. ovata.* (*Ophrys ovata*; *Linn. Sp. Pl.* 1340. *Sm. Fl. Brit.* 932. *Engl. Bot.* t. 1548. *Curt. Lond. fasc.* 3. t. 60.) Frequent in woods, flowering in June like most of its genus. The stem, a foot high, bears only two opposite, broad, oval leaves, and a spike of numerous small green flowers, whose long pendulous lip produces a small drop of honey in front, thus proving its right to the title of nectary. See *Sm. Intro. to Botany*, 461.

11. *E. cordata.* (*Ophrys cordata*; *Linn. Sp. Pl.* 1340. *Sm. Fl. Brit.* 933. *Engl. Bot.* t. 358.) Grows on boggy mountainous heaths in Scotland and the north of England, as well as in Switzerland, &c. It is scarcely a quarter so large as the last, and has heart-shaped leaves, and a four-lobed lip.

12. *E. convallarioides.* *Sw.* in *Web. and Mohr. Beitr.* v. 1. t. 1. (*Ophrys cordata*; *Michaux Fl. Boreali-Amer.* v. 2. 158.) Native of the West Coast of North America, and of Newfoundland. A slender delicate species, with a pair of roundish heart-shaped leaves, capillary racemose flower-stalks, narrow calyx and petals, and a dilated lip.

13. *E. camtschatea*. Sw. and Willd. (*Ophrys camtschatea*; Linn. Sp. Pl. 1343. Neottia; Amæn. Acad. v. 2. 361. t. 4. f. 24.) Native of Siberia. Destitute of leaves, except a few sheathing scales. The flowers are much like the last, but have a more linear nectary.

14. *E. unifolia*. (*E. porrifolia*; Sw. and Willd. *Ophrys unifolia*; Forst. Prod. 59.) Found by Forster in New Zealand. The leaf is solitary and sheathing, rising above the stalk, which it embraces, and which bears a short dense spike of small flowers. We see no advantage in changing the original specific name.

EPIPEDOMETRY, of *επι*, *παις*, *foot*, and *μετρος*, *I measure*, in *Mathematics*, signifies the measuring of figures that stand on the same base.

EPIPETRON, in *Botany*, a name given, by Theophrastus and Aristotle, to a plant, supposed by many to be the same with the empetrum of Dioscorides. But there is great reason to doubt whether the epipetron of the two older authors be the same plant; and whether, if they mean two different plants by this name, either of them agree with the empetrum of Dioscorides. Theophrastus says, that his epipetron never flowers: and Aristotle says, that his epipetron grows on rocky places, and continues to grow after it is taken up, as the orpin and some other plants will do.

EPIPHÆNOMENA, of *επι* and *φανομενον*, *symptom*, in the *Writings of the Ancient Physicians*, a term used to express such of the symptoms, in certain diseases, as did not usually appear till the time that the disease was actually formed, called also epiginomena.

EPIPHALLUS, in the *Ancient Music*. It appears by a passage in Eustathius, often quoted by Meursius, that this was also the name of a dance, performed to flutes.

EPIPHAN, in *Geography*, a town and district of Russia, in the government of Tula, situated on the Don.

EPIPHANES. See EPIPHANIUS. This term in Greek, *Επιφανης*, denoted eminent or illustrious, and thus it was applied to Antiochus, which see.

EPIPHANES, of *επι* and *φανομαι*, an epithet given to Jupiter, because he manifested his presence by lightning and thunder, &c.

EPIPHANIA, a word used, by some of the ancient physicians, to express the external habit of the body.

EPIPHANIA, in *Ancient Geography*, a town of Asia Minor, in Cilicia, near the Mediterranean, between the branches of mount Amanus, on the river Carus; probably denominated Epiphania in honour of Antiochus Epiphanes, king of Syria, who possessed Cilicia. We learn from Tacitus, that the part in Cilicia, in which this town was situated, became subject to the dominion of Rome under Lucullus, about the year of the city 683. It was afterwards episcopal under the metropolis of Anazarba.

EPIPHANIA on the *Euphrates*, a town of Asia, situated on that river.

EPIPHANIA, a town of Syria, on the Orontes; which was subjected to the Romans about the year 690, during Pompey's expedition into the territory of Apamæa and into Coele Syria. This town was situated between Larissa and Arethusa; and it was reckoned by the Orientals one of the most ancient towns in the world, founded, as they imagined, by Hamath, one of the sons of Canaan; and that its name was changed by the Macedonians in honour of Antiochus Epiphanes. (See HAMATH.) It was episcopal under the metropolis of Apamæa.

EPIPHANIA, a town of Asia Minor, in Bithynia. Steph. Byz.—Also, a town of Asia, on the banks of the Tigris, called by Steph. Byz. *Arseicerta*.

EPIPHANIUS, or EPIPHANES, in *Biography*, the son of Carpocras, or Carpocrates, an heresiarch in the second century, was instructed by his father in the whole circle of the sciences, and particularly in the Platonic philosophy; but his death, when he was 18 years of age, disappointed the hopes which the Carpocratians entertained concerning him. After his death he was honoured by them as a god, particularly in the island of Cephalonia, where a temple was erected to him, with altars, a grove, and a museum, and where the day of his nativity was celebrated with hymns, libations, sacrifices, and feasting. These are the reports of Clement of Alexandria and of Epiphanius; unconfirmed by the testimony of other writers. Epiphanius is now classed with the Valentinians. Lardner Hist. Heret. c. iii. § 1.

EPIPHANIUS, bishop of Salamis in the island of Cyprus in the fourth century, and dignified by the Catholics with the title of Saint, was born in the vicinity of Eleutheropolis, in Palestine, about the year 320. In his youth he went into Egypt, where he inclined to the sect of the Gnostics, but separating from them, he joined himself to the Egyptian Ascetics, imbibing their principles and conforming to their manners. In his 20th year he returned to his own country, and became a disciple of Hilarion, the father of Palestine monkery. After some time he founded a monastery at Bezanduce, the village in which he was born, over which he presided for the greatest part of his life. In 367 or 368, he was appointed bishop of Salamis, afterwards called Constantia, where his piety and sanctity were held in high estimation, and where he was assiduously employed in writing defences of the orthodox doctrines against the attacks of heretics. His zeal, however, involved him in many troubles, which embittered a considerable portion of his life. One of the principal circumstances which contributed to embarrass and embroil him, and to entail disgrace on his memory, was his inveterate opposition to the opinions of Origen. This produced a contest with John bishop of Jerusalem, who favoured these opinions, which, after many mutual invectives and recriminations, terminated in a breach between the two bishops, that convulsed the eastern churches by the hatred and persecuting spirit manifested in the conduct of their respective partisans. Theophilus, bishop of Alexandria, was an active adherent to the cause of Epiphanius, and held a council in 399, which condemned the writings of Origen, and prohibited all persons from reading them, or having them in their possession. This example was followed by a council of the bishops of Cyprus, summoned by Epiphanius himself in the year 401. Failing of success by the decrees of these councils and by the persecution against Origen, which they were the means of instigating, the determined and zealous prelate took a voyage to Constantinople, in order to induce the bishops in that city to adopt and sanction the decrees of Alexandria and Cyprus. On his arrival, he declined holding any intercourse with Chrysofom, bishop of that city, unless he joined in the condemnation of Origen, and in withdrawing his protection from the exiled Egyptian monks. Exasperated by the disappointment of his views, he resolved to present himself to the people in the church of the Apostles, and openly to condemn the books of Origen, and all his advocates. But before he could execute his purpose, he was warned of the irregularity of his proceedings, and of the sedition which they might occasion; and he, therefore, thought it most prudent to abandon his design. His next attempt was that of interesting the court in his favour; and so violent and implacable was his zeal against those who favoured Origen, that

that when the empress Eudoxia besought his prayers in behalf of the younger Theodosius, who was dangerously ill, he assured her that he should not die, if she would consent to discard the heretics, who were sheltered under the imperial patronage. The princess very properly reproved this arrogant and impious message; and his impetuosity was also checked by the Egyptian monks, who convicted him of being unacquainted with the principles of the persons, against whom he had been indeliberately exciting universal indignation. Thus foiled and abashed, he set out on his return to Cyprus, and died either on his voyage, or soon after his return, in the year 402 or 403, at a very advanced age. The piety of Epiphanius was unquestionable; but it was blended with a gloomy superstition, which led him to promote the austere discipline of the cloister, and to employ his episcopal influence in multiplying monastic institutions. In offices of charity for the relief of the indigent, he expended not only his own private fortune, but the greatest part of the revenues of his church, and large sums entrusted to his disposal. His learning was considerable, for, according to St. Jerome, who mentions him in terms of high commendation, and calls him *πενταγλωσσος*, a man of five languages, he understood Greek, Syriac, Hebrew, Egyptian, and partly Latin. It is allowed, however, that he was deficient in judgment, and unskilful in wielding the weapons of controversy. Careless in his transcripts from ancient authors, and credulous in admitting unauthenticated reports, he has been betrayed into various contradictions and absurdities, so that his works, with respect to authority and reference, are depreciated in value. His style is mean, harsh, and unpolished, without perspicuity, and without connection. In his remaining works he has given several catalogues of the books of the Old and New Testament. His canon of the Old Testament was much the same with that of the Jews. (See CANON.) The books of the New Testament received by him are the same with those generally received by us. For both these classes of sacred books he professes the highest regard; nor does he ever make use of Christian apocryphal books, written in the name of apostles and falsely ascribed to them. With respect to the books of the New Testament, he says, that Matthew preached, and wrote his gospel in Hebrew, and that he was the only writer of the New Testament who used this language. He had heard, however, that the gospel of St. John, and the Acts of the Apostles, had been translated from Greek into Hebrew, and were in the library of the Jews at Tiberias. Matthew wrote first, and soon after Mark, who was Peter's companion at Rome. The third gospel, in his enumeration, was that of Luke. John wrote his gospel at the age of 90 years, and Epiphanius says, that it was occasioned by the errors of the Ebionites, the Cerinthians, the Merinthians, and Nazarenes. He ascribes the book of the Acts to Luke. He frequently quotes the epistle to the Hebrews as Paul's; he also cites the epistle of James, the two epistles of Peter, John's first and second epistles, and the Catholic epistle of Jude. He also received the book of Revelation. Of the baptism of Christ, he says, that it took place when he was 29 years and 10 months, thus understanding St. Luke's words, iii. 23. He says, there are two passovers in our Lord's ministry, according to St. John's gospel, and that he suffered at the third passover, in the 33d year of his life on earth; and therefore he did not think the "feast of the Jews," mentioned John, v. 1. to be a passover. He says, that the apostles did not preach themselves, but Jesus Christ, Lord. Therefore there was no sect, or church, called after the apostles; for we never heard of Petrians, or Paulians, or

Bartholomeans, or Thaddeans, but of Christians only; as they were called at Antioch. The works of Epiphanius were first printed in Greek at Basil by Oporinus in 1544; and the subsequent impressions have been numerous, of which the most valuable is that published at Paris in 1622, in two volumes folio, by the learned Petavius, who gave a new Latin version, with critical notes and observations. This edition was afterwards printed at Cologne in 1682, in two volumes folio. Cave's H. L. vol. i. sub sæc. Arian. Lardner's Works, vol. iv.

EPIPHANIUS, surnamed "The Scholastic;" a native of Italy, and an eminent Greek and Latin scholar, was born about the year 310. At the request of Cassiodorus he translated into the Latin language the ecclesiastical histories of Socrates, Sozomen, and Theodoret, a version more entitled to commendation for its fidelity than its elegance. Cassiodorus was also indebted to Epiphanius for the improved version of the "Codex encyclicus," or collection of synodal letters of the year 458, addressed to the emperor Leo, in defence of the council of Chalcedon. Cave H. L. vol. i. sub sæc. Eutych.

EPIPHANIUS, patriarch of Constantinople in the 6th century, strenuously vindicated the orthodox doctrines against the Eutychians, and after elevation to his dignity in the year 520, procured the condemnation of the latter in a synod of bishops held at Constantinople. Whilst he was patriarch, the decrees of the council of Chalcedon were confirmed, and a reconciliation was completed between the churches of Constantinople and Rome, after a schism which lasted 35 years. Five letters of this patriarch to pope Hormisdas on the subject of the union are extant in the 4th volume of the collection of the Latin councils. Cave H. L. vol. i. sub sæc. Eutych.

EPIPHANY, in *Ecclesiastical Antiquity*, the feast of kings; a double festival, of the first rank, solemnized on the sixth of January, commonly called "Twelfth day," in honour of the appearance of Jesus Christ to the three kings, or magi, who came to adore, and bring him presents.

The feast of Epiphany, now held in honour of the adoration of the magi, had its first institution among the Greeks, from a different object, viz. our Saviour's birth; and was called theophany, and epiphany, that is, appearance, and manifestation, of God.

Pope Julius, who reigned from the year 337 to 352, was the first who taught the church to distinguish the feasts of the nativity and epiphany. Papebroch. Paral. ad Conat. p. 23. Act. SS. Maii, tom. vii.

The word in the original Greek, *επιφανια*, signifies *appearance*, or *apparition*; and was applied, as some critics will have it, to this feast, on account of the star which appeared to the Magi. St. Jerom and St. Chrysostom, take the Epiphany for the day of our Saviour's baptism, when he was declared to men by the voice, "Hic est Filius meus dilectus, in quo mihi complacui: This is my beloved Son, in whom I am well pleased." And accordingly it is still observed by the Coptæ and Ethiopians in that view. (See Ludolph. Hist. Æthiop. lib. xxi. cap. 2.) Others contend, that the feast of Christmas, or the nativity of our Saviour, was held in diverse churches on this day; which had the denomination Epiphany, or appearance, because of our Saviour's first appearance on earth, as at that time. And it must be allowed, that the word is used among the ancient Greek fathers, not for the appearance of the star to the magi, but for that of our Saviour to the world. In which sense, St. Paul used the word *επιφανια*, *epiphania*, in his second epistle to Timothy, chap. i. ver. 10. Ammianus Marcellinus makes mention of this feast, lib. xxi. cap. 2.

and observes, that it was held in January. Upon which passage Valeſius, in his notes, endeavours to ſhew, that the hiſtorian meant by Epiphany the feaſt of the nativity.

The heathen writers uſed the word epiphania in the like ſenſe, *viz.* to expreſs the appearance of their gods on earth. And the Chriſtians, after their example, applied it, in the general, to expreſs any appearance, or manifeſtation of the Deity.

EPIPHEOS, in *Botany*, the name given by the ancients to the dodder, or *cuscuta*, which grew upon the ſhrub they called *phæos*. This was the ſtæbe of the modern Greeks, deſcribed by Honorius Bellus. It was a cuſtom, among the old writers, to name the *cuscuta*, or dodder, from the plant it was found growing upon, as they ſuppoſed that it in ſome degree partook of the virtues of that plant. Thus that which grew upon thyme was called *epithymum*, and that upon the nettle, *epiurteca*, and that upon flax, *epilinum*; ſo of many others.

The ſhrub *phæos* was alſo called *ſtæbe* by Dioſcorides and Theophrastus; and hence this dodder was ſometimes called *epiſtæbe*.

EPIPHLEBOS, of *επι* and *φλεβ*, a vein, in the *Writings of the Old Phyſicians*, a term uſed to denote ſuch perſons as were lean, and of a hot temperament, and whoſe veins, for that reaſon, appeared uſually very turgid and prominent in the hands, &c.

EPIPHLOGISMA, (from *επι*, and *φλογίζω*, to inflame,) in *Surgery*, a violent inflammation, accompanied with pain, ſwelling, and redneſs. Alſo, a great internal heat: likewiſe, the affection uſually called *eryſipelas*.

EPIPHONEMA, *Επιφωνημα*, *Acclamation*, in *Rhetoric*, a ſententious ſort of exclamation, which is frequently added after a narrative, or rehearsal of any thing remarkable; containing uſually a lively, cloſe reflexion on the ſubject there ſpoken of and intended to give it greater force, and render it more affecting to the hearers.

Such is that of St. Paul, when, after diſcourſing of the rejection of the Jews, and the vocation of the Gentiles, cries out,

“ O the depth of the wiſdom and knowledge of God !”

Such alſo is that of Lucretius, after relating the ſtory of Agamemnon's ſacrificing his daughter Iphigenia :

“ *Tantum religio potuit ſuadere malorum.*”

This figure is frequently expreſſed in a way of admiration. Such is that of Cicero, when after having obſerved, that all men are deſirous of living to an advanced age, but uncaſy under it when attained, he makes this juſt reflection upon their conduct: “ So great is their inconſtancy, folly, and perverſeneſs !” (*Cic. de Senect. c. 2.*)

The epiphonema is uſually expreſſive of the milder and more gentle paſſions, and is not ſo vehement and impetuous as exclamation.

EPIPHORA, (from *επιφερω*, to carry with force,) in *Surgery*. The original import of the word “ epiphora” ſeems to have been a violent determination of fluids to any part of the body. At preſent, however, all ſurgeons confine the meaning of the term to an affection, in which the tears, not being able to paſs in a proper manner down into the noſe, accumulate in front of the eye, and trickle over the cheek. The diſorder is alſo not unfrequently denominated the “ watery eye.”

Whoever is in the habit of conſulting ſurgical books, will ſoon perceive, that writers do not make a clear diſtinction between the epiphora, and ſome ſtates of the *ſiftula lachrymalis*. Thus Mr. Ware has particularly conſidered the

ſpecies of epiphora, which, he ſays, “ is produced by an obſtruction to the free paſſage of the tears from the eye into the noſe. This obſtruction (he adds) may take place either in the ducts leading from the *puncta lachrymalia* into the lachrymal ſac, or in the ſac itſelf. When the ducts are obſtructed, a caſe which rarely occurs, the tears fall over the cheek, and the ſac is conſtantly empty. Preſſure on the ſac, therefore, can produce no regurgitation, either of tears, or mucus, into the eye. The method of cure is here evident. A ſmall probe of a ſuitable ſize muſt be introduced through the *puncta* of the obſtructed ducts into the ſac, and this operation be daily repeated until the obſtruction be removed. But, (continues Mr. Ware,) the part in which the obſtruction more commonly lies, is in the ſac itſelf; and in this caſe, the tears, mixed ſometimes with mucus, flow back into the eye through the *puncta*, when preſſure is made on the ſac.” Now, this latter kind of diſeaſe, Pott, Scarpa, and other diſtinguiſhed ſurgical authors, conſider only as one ſtage of the *ſiftula lachrymalis*.

We do not mean, however, by what has been ſtated, to make any attempt to defend the manner in which the expreſſion “ *ſiftula lachrymalis*” is employed; our ſole aim is to ſhew, that, unleſs a line of diſtinction is drawn between what ſhould be called “ epiphora,” and what “ *ſiftula lachrymalis*,” the comprehension of the ſubject is rather embarrassed, than promoted, by having two different terms, which ſo glaringly encroach upon each other in the extent of their ſignification. The epiphora, in the meaning of a mere weeping of the eye, may ariſe from a variety of cauſes, which muſt be removed, ere the complaint can be cured. An encanthis, or any other kind of tumour in the inner angle of the eye, a polypus in the noſe, an ectropium, a trichiaſis, &c. may obſtruct the due flowing of the tears into the noſe, and thus make them fall over the ſubjacent cheek, ſo as to occaſion an epiphora. This latter diſorder may alſo be the conſequence of a part of the *caruncula lachrymalis* having been loſt, either by diſeaſe, or an unſkilful employment of the knife in ſome previous operation. An epiphora is always attendant on obſtructions in the *ductus naſalis*. Mr. Ware obſerves, with regard to another ſpecies of epiphora, originating from a too copious ſecretion of tears, that, if it does not depend on an affection of the mind, its more remote cauſe is uſually an inflammation of the eye. In this inſtance, a cure is to be effected by ſubduing the ophthalmia, and afterwards ſtrengthening the eye by mild aſtringent applications, ſuch as cold water, either alone, or containing a ſmall quantity of the *zincum vitriolatum*.

When the membrane, which lines the lachrymal ſac, is in a morbid ſtate, the mucus which it ſecretes is often ſo thickened, that it becomes incapable of paſſing through the ſac, and lodging in this ſituation, prevents the natural and regular deſcent of the tears from the eye into the cavity of the noſe.

This ſpecies of epiphora has occaſionally been benefited by the unguentum *hydrargyri nitrati*, applied to the edges of the eye-lids, and rubbed into the ſkin over the lachrymal ſac. Relief is alſo alleged to have been derived from the uſe of ſtimulating applications to the inſide of the noſe, which applications are ſuppoſed to have acted by increaſing the ſecretion from the pituitary membrane.

However, we muſt confeſs, that no men of experience, at the preſent day, place ſufficient reliance on the preceding methods, to recommend them to be tried by their patients. At the ſame time it ſhould be underſtood, that theſe plans are ſometimes exceedingly proper to be adopted in conjunction with other more efficacious meaſures.

## EPIPHORA.

In the year 1712, M. Anel recommended the introduction of a probe, and then the injection of a fluid, through the puncta lachrymalia, with a view of clearing away whatever matter might prevent the tears from readily finding their way through the lachrymal sac and nasal duct into the nose. M. Anel relates, that he accomplished many striking cures in this manner; and Heister confirms the efficacy of the plan, by appealing to his own practice, in which he had often produced a complete recovery in the short space of three days.

In the year 1780, sir William Blizard considered, that when water was injected through the punctum lachrymale, it not only had but very little specific weight, but was driven through the lachrymal sac in an unfavourable direction. These reflections led him to make the proposal of introducing quicksilver through a small pipe, which communicated with a long tube full of this metal. Sir William Blizard was of opinion, that the quicksilver, in consequence of its great weight, would have more power when the sac was filled with it, of removing the obstruction, than the mere injection of water. This gentleman also, in a paper read to the Royal Society, states, that he had produced a cure by the introduction of quicksilver in an example which had lasted seven months; and that the mercury passed readily through the ductus nasalis, at the third and fourth times of repeating the operation.

When the celebrated Mr. Ware was in Paris, in the year 1791, he learnt from Messieurs Grandjean and Monsieur Arrachart, eminent oculists in that city, that the plan of injecting water through the puncta lachrymalia, in incipient cases of fistula lachrymalis, was not given up in France. Mr. Ware even saw some troublesome cases cured on the continent in this way. Hence he was determined, on his return to London, to give Anel's operation a fuller trial than he had previously done. For this purpose he got Mr. Pepys, in the Poultry, to construct a small silver syringe, with pipes of different sizes adapted to it.

The following case, which afforded Mr. Ware the first opportunity of ascertaining more carefully the efficacy of Anel's treatment, is related in his own words, and will serve to inform the reader of several useful practical circumstances.

"A lady in Great Russell-street came under my care, who for many months had been subject to an epiphora of the left eye, which prevented her both from reading and working with her needle, without undergoing great inconvenience. Whenever she employed herself in any way that required close attention, her eye became overspread with tears, and the sight was so much confused, that it obliged her to leave off almost as soon as she began. A great variety of remedies had been applied, under the direction of different medical men, but none of them produced any essential amendment. On examining the eye, I observed that the tunica conjunctiva, near the inner angle of the eye-lids, was slightly inflamed; and on pressing the lachrymal sac with my finger, I perceived that a tear regurgitated through the lower punctum. This appearing to be a proper case for the use of the syringe, I immediately determined to employ it. But I found, that though a tear came through the lower punctum on my pressing the sac, yet this punctum was so small that it would not admit the point of the smallest syringe I then had. I introduced into it, however, a small probe, and by means of this I so far dilated the orifice, that it admitted the point of the syringe on the next day without any difficulty. Upon my first using the injection, the water escaped through the upper punctum almost as fast as it was introduced through the lower; but, notwithstanding

this, I persevered in urging the liquor on, until the whole contents of the syringe were exhausted. I repeated the injection three times the same day in immediate succession. The lady, however, was not sensible that any part of the water passed through the duct into the nose during either of these operations; and indeed it soon became evident that none had passed; for, having cleared her nose before I began, on her blowing it again immediately afterwards, she could produce no moisture on her handkerchief. I repeated the operation three times, both on the second and on the third day; and each day, during the time that the water was passing, I not only endeavoured to prevent it from coming through the upper punctum, by covering it with the point of my finger, but I occasionally pressed the lachrymal sac in order to give the water an inclination downward. On the fourth day I very plainly perceived, on the patient's clearing her nose after the operation, that a part of the water had passed through the duct; and, the next morning, I had the satisfaction to hear, that the eye, on the preceding day, had watered much less frequently than it had done for a considerable time previous to it. I repeated the process above-mentioned about ten times, in as many days, and I observed that the quantity of water which passed through the duct was augmented every time I used it. The tears, after this, resuming their natural course, the lady recovered the power to read and work without any inconvenience." (See Ware on the Epiphora.)

Mr. Ware, in his practice, uses common water for the injection, sometimes in a cold state, but more frequently warmed. The pipes which this gentleman employs, are also much shorter than the one represented by Mr. Benjamin Bell in his System of Surgery, (vol. iii. pl. 37). They are also a little arched towards their point. Mr. Ware thinks, that when they are made in this manner, they can be more conveniently introduced into the punctum lachrymale, than when long and straight. He recommends always having ready several pipes of different sizes, and using the largest one which can be introduced without pain. He finds it also advantageous to stand either behind the patient or on the side opposite to that of the diseased eye; and high enough to have a full command of the patient's head. Thus the operator will gain a complete view of the lower punctum, which will also be in a convenient position to receive the pipe of the syringe. Mr. Ware, moreover, advises us to remove the finger from the lower eye-lid as soon as the pipe is introduced, and to place it over the upper punctum, so as to prevent the fluid from escaping through this aperture. The same finger is likewise to be occasionally used in making pressure on the lachrymal sac, in order to aid in forcing the injection down into the nose.

Mr. Ware has published some additional remarks on the epiphora, and makes some very valuable observations on the treatment of another species of the disorder; we allude to that kind which proceeds from a thickening of the membrane which lines the lachrymal sac and duct, and a spasmodic constriction in any part of this passage, conjoined, perhaps, with a morbid secretion of thickened mucus. Mr. Ware imputes a few occasional failures, in the above simple mode of treatment, to the causes of the disease being sometimes of this nature. The following extract will explain the different methods to which this celebrated oculist has recourse in different cases.

"I in general begin the treatment by injecting some warm water through the inferior punctum lachrymale, and I repeat the operation four or five days in succession. If, in this space of time, none of the water pass through the duct

duct into the nose, and if the watering of the eye continue as troublesome as it was before the injection was employed, I usually open the angular vein, or direct a leech to be applied near the lachrymal sac; adding here a caution, that the leech be not suffered to fix on either of the eye-lids, lest it produce an extravasation of blood in the adjacent cells. About the same time that blood is taken away in the neighbourhood of the eye, I usually vary the injection, and try the effects either of a weak vitriolic, or anodyne, lotion. In some instances also, when I have found it impossible, after several attempts, to inject any part of the liquid through the duct, I have introduced a golden probe, about the size of a bristle, through the superior punctum lachrymale, and, attending to the direction of the duct, have insinuated its extremity through the obstruction, and conveyed it fully into the nose; immediately after which I have found, that a liquid, injected through the inferior punctum, has passed without any difficulty; and, by repeating these operations, for a few successive days, I have at length established the freedom of the passage, and completed the cure. In other instances, I have recommended a strongly stimulative sternutatory to be snuffed up the nose, about an hour before the time of the patient's going to rest, which, by exciting a large discharge from the schneiderian membrane, has sometimes also greatly contributed to open the obstruction in the nasal duct.

"Cases occur very rarely which may not be relieved by some of the means above related." (Ware's Additional Remarks on the Epiphora.)

When the discharge has been fetid, Mr. Ware has sometimes found, that a vitriolic lotion, injected into the sac, has quickly corrected the quality of the matter.

Scarpa, in his "Osservazioni sulle principali Malattie degli Occhi," maintains, that the chief part of the yellow viscid matter, which accumulates in the lachrymal sac, is secreted by the lining of the eye-lids, and by the little glands of Meibomius; and that the altered quality of this secretion has a principal share in the cause of the disease. He states, that the truth of this fact may at once be ascertained by everting the eye-lids; and especially the lower one of the affected side; and by comparing them with those of the opposite eye. The former will always exhibit an unnatural redness of the internal membrane, which has a villous appearance, all along the extent of the tarsus, while their edges are swollen; and numerous varicose vessels are distinguishable on its surface. The follicles of Meibomius are also turgid and prominent.

Hence, Scarpa advises making such applications to the inside of the eye-lids, as have a tendency to improve the quality of the secretion from them, at the same time, that attempts are made to remove the obstruction in the ductus nasalis. Mr. Ware, indeed, had previously noticed, that such treatment may occasionally be proper.

"When an epiphora is occasioned by an acrimonious discharge from the sebaceous glands on the edges of the eye-lids, it must be evident, that injections into the sac will be very insufficient to accomplish a cure, because the sac is not the seat of the disorder. The remedies that are employed must be directed, on the contrary, to the ciliary glands themselves, in order to correct the morbid secretion that is made by them; and for this purpose, I do not know any application that is so likely to prove effectual as the unguentum hydrargyri nitrati of the new London Dispensatory, which should be used here in the same manner in which it is applied in common cases of the psorophthalmia. It will be proper to cleanse the eye-lids every morning, from the gum that collects on the edge during the night, with

some soft unctuous application; and I usually advise to apply to them two or three times in the course of the day a lotion composed of three grains of white vitriol, in two ounces of rose, or elder-flower, water."

Mr. Ware very judiciously censures the plan of applying collyria to the eye by means of linen, wet in them; and he recommends eye-glasses for the purpose, or insinuating the fluid, between the eye and eye lids, with a camel-hair pencil, thoroughly wet in the application. (Additional Remarks on the Epiphora.)

Scarpa also extols washing the eye, three or four times a day, with a vitriolic collyrium; and, besides praising the ointment recommended by Mr. Ware, he recommends Janin's ophthalmic ointment, to be smeared over the margins and lining of the eye-lids every morning and evening.

R. Adipis. Suille. Tutia præp. Bol. Armen. ſing. ʒij. Calcis Hydrarg. alb. ʒj. Miscce. To be used at first lowered with a larger proportion of lard, than is above ordered. See FISTULA Lachrymalis.

EPIPHYLLOSPERMOUS PLANTS, of *επι, φυλλον, leaf*, and *σπέρμα, seed*, are the same with the capillaries, herbs which bear their seed on the back part of their leaves. See CAPILLARY.

EPIPHYLLUM, in *Botany*, *επι, υρον*, and *φυλλον, a leaf*, from the mode in which the flowers grow upon a flat stem resembling a leaf, see CACTUS *Phyllanthus*, sp. 40.

EPIPHYSIS, in *Anatomy*, is a name given to certain parts of bones at a particular period of their formation. See BONE.

EPIPLA'SMA, from *επι*, and *πλάσσω, to spread*, in *Surgery*, the name of an application to wounds: it consisted of wheat meal boiled in hydreæum.

EPIPLOCE, *Επιπλοκη*, in *Rhetoric*, the same with *climax*, which see.

EPIPLOCE'LE, from *επιπλον, the omentum*, and *κηλη, a tumour*, in *Surgery*, an omental hernia, or a rupture formed by a protrusion of a piece of omentum from the cavity of the abdomen.

Le Dran informs us, that in an epiplocele there is nothing to be felt, except a deughy softness, which neither absolutely yields to the touch, nor very sensibly resists it. The tumour has a flabby unequal feel; and, when there is no stricture, is perfectly indolent. It is more compressible than that arising from protruded intestine, and, when the quantity of omentum is large, the epiplocele may, in some measure, be distinguished by its weight.

As the subject of omental ruptures will be particularly considered under the head HERNIA, we shall, for the present, content ourselves with referring to the latter article.

EPIPLOIC, in *Anatomy*, a term applied to parts which belong to the epiploon, or omentum; thus we have epiploic arteries, &c.

EPIPLOOMPHALON, from *επιπλον, the omentum*, and *ομφαλος, the navel*, in *Surgery*, an omental hernia protruding at the navel.

EPIPLOON, in *Anatomy*, called also omentum or cawl, is a membranous expansion contained in the cavity of the abdomen: and continued from the peritoneal covering of some of the viscera. There are two very distinct productions, of the nature just described, distinguished by the appellations of minus and majus, from their difference in size; and by those of hepatico-gastricum, and colico-gastricum from their situation. But when the epiploon, or omentum, is spoken of generally, the greater or colico-gastric portion is understood. To the peritoneal surface of the large intestine are attached numerous small processes,

## EPIPLOON.

which resemble the epiploa in their apparent structure, and are called *appendices epiploicae*.

Although the omenta are usually represented by anatomists as processes of the peritoneum, their organization differs essentially from the structure of that membrane. Their groundwork or basis consists of the most delicate and transparent membrane of the body; which is lacerated on the application of very slight force. This membrane is composed obviously of two layers, connected by cellular tissue, and containing numerous venous and arterial ramifications. A greater or smaller quantity of fat is deposited between these layers, and in the course of the vessels. When this deposition is very considerable, as in very corpulent individuals, or in animals who have been fattened for the slaughter, the peculiarly transparent delicate appearance of the omental membrane is entirely destroyed, and the part is converted into a layer of fat. Ordinarily, however, the adipous substance is confined to the neighbourhood of the blood-vessels, accompanying them in their subdivisions, but leaving intervals in which the membrane exhibits its distinguishing diaphanous appearance. In emaciated subjects, during the period of infancy, and particularly in the foetal state, the quantity of fat is very trifling. Under such circumstances we can observe most distinctly that the deposition of fat is confined to the course of the vessels. As the omenta are entirely unconnected to the parts on which they lie, as well as to those by which they are covered, both their surfaces are smooth and glistening, and moistened like those of other serous membranes, by a serous exhalation, which facilitates their motions over the neighbouring organs. Analogy warrants us in ascribing this secretion to the arteries of the omenta; and we consequently consider these organs as an extension of the general serous surface of the abdominal cavity.

Experiments on living animals, and surgical operations, clearly prove that the membrane of the omenta possesses little, if any, sensibility in its healthy state.

The *lesser epiploon, mesogaster, omentum minus, or hepaticogastricum*, is the portion extended from the small arch of the stomach to the concave or under surface of the liver. It arises, behind, from the posterior half of the transverse fissure of the liver; on the right it is continuous with the peritoneum covering the neck of the gall-bladder and the beginning of the duodenum; towards the left it is reflected immediately from the diaphragm. Advancing from these points, in two closely united layers, towards the stomach, it is attached to the end of the oesophagus, to the whole lesser arch of the stomach, to the pylorus, and commencement of the duodenum. At this line its layers divide, and expand over the stomach, one of them forming the superior, and the other the inferior peritoneal covering of this viscus. Between the layers of the lesser omentum are contained the hepatic vessels and biliary ducts, the coronary vessels of the stomach, some branches of the coeliac plexus of nerves, and of the par vagum, and a few absorbent glands. Fat is rarely deposited here in so large a quantity as in the large epiploon, so that we can usually see through it that portion of the liver called lobulus spigelii, which is in contact with its inferior surface.

The biliary ducts, the hepatic vessels with numerous accompanying branches of nerves from the coeliac ganglia, and a considerable portion of the hepatic and cystic absorbents, connected and surrounded by adipous and cellular substance, are inclosed in the right edge of the lesser omentum. This part is called *capsula Glissoni*, from an English anatomist, who described it minutely in a work entitled "De Hepate." The very margin of the omentum is occupied by the biliary

ducts, and the neck of the gall-bladder. At this border the two surfaces of the little omentum are continuous. Behind the unconnected edge, round which the peritoneum turns, is found the foramen of Winslow, or *foramen epiploicum*, large enough to admit one or two fingers, which can thus be placed in immediate contact with the back part of the liver, and the inferior surface of the little omentum. This opening is situated between the neck of the gall-bladder, and the beginning of the duodenum, with the hepatic vessels in front, and the vena cava behind. It is not unusual to find its edges adhering together. We shall have occasion to mention it again after describing the large omentum.

The great omentum, *epiploon majus, vel gastro-colicum*, is the loose membrane, more or less loaded with fat, lying in front of the bowels, and generally meeting our eye in laying open the abdomen. It differs extremely in length and situation; in some cases reaching as low as the pelvis, and often descending in ruptures to the very bottom of the scrotum; while in others it extends but a short way below the umbilicus. It is always shorter in children than in adults. We often find it folded, or rolled on itself, and drawn to some one part of the abdomen, or tucked up over the stomach, so as to leave the small intestines exposed to our immediate view. Its natural situation between the bowels, and the parietes of the abdomen, explains the frequency of its protrusion, together with the intestines, in hernia. Some anatomists assert that it hangs lower on the left than on the right side of the abdomen.

The great omentum is a continuation of the peritoneal covering of the stomach. We have already described this as being formed by the separation of the two layers which constitute the little omentum. At the great curvature of the stomach these layers again coalesce into one sheet of membrane, are produced till they meet with the transverse arch of the colon, to inclose which they again separate. Meeting at the opposite line they once more unite, and are continued under the name of the transverse mesocolon to the root of the mesentery. The origin of the great epiploon, when minutely examined, commences in the left from the end of the oesophagus, and from the notch of the spleen (where it forms a membranous connection between this organ and the stomach) and includes the whole of the great arch of the stomach nearly as far as the pylorus. The portion of membrane thus formed descends loosely before the transverse arch of the colon, and reaches to different lengths beyond it, constituting the anterior layer, or *lamina gastrica* of the great epiploon. At the lower or floating border this membranous expansion is doubled on itself, and turning upwards again to meet the transverse arch of the colon, forms the posterior layer, or *lamina colica* of Haller. On the right side the great omentum is not only attached to the transverse portion of this intestine, but is continued along its hepatic flexure, and for some way down the ascending colon. In some instances it reaches as low as the caecum. It is this lateral extension of the great omentum which constitutes the *omentum colicum* of Haller. Each of the layers is composed of a duplicature of peritoneum, as we have before stated, containing its proper vessels, and fat, and united closely by cellular tissue. It will be evident, from our description, that the great omentum is formed by the anterior layer alone in the space between the stomach and transverse arch of the colon; below the latter it is composed of the two layers, the lamina gastrica, and the lamina colica lying in contact with each other, but having no further connection in a healthy state of the opposing surfaces.

From this disposition of the great and little epiploa,

there results, in conjunction with the inferior surface of the stomach, and the superior surface of the transverse mesocolon a membranous bag, called usually the bag of the omentum. It offers every where on the inside a continuous serous surface, where the sides of the cavity are in close contact, but not adherent. The communication between this pouch, and the general cavity of the peritoneum, is formed by the foramen of Winslow. In order to demonstrate this fact, as well as to display the bag formed by the omenta, we introduce into this opening a pipe, surrounded by some soft substance, to prevent the escape of the air. By blowing gently we are enabled to separate the layers of the great omentum, which were in contact, and give to the whole the form of a large membranous bag, intersected by vessels and bands of fat, between which the membrane rises in pouches of various sizes. The lines formed by the stomach, and transverse arch of the colon, are but faintly seen, owing to the distention of the epiploon, which appears, as it were, suspended between them. To insure the success of this experiment some conditions are necessary, which we are not always happy enough to bring together. There must be no adhesion of surfaces, no large accumulation of fat, the subject young, and the whole conducted with the greatest delicacy, as the slightest rent in the membrane is sufficient to prevent success. In the fœtus, and in young children, the laminae of the great omentum are easily separable throughout their whole extent. In adults, and more so in old persons, they are generally more or less united, so that the cavity of the omenta is confined to the space contained between the little omentum, the under surface of the stomach, and the transverse mesocolon.

The arteries of the great omentum are derived from the right and left gastro-epiploic vessels. They are in general small, and descend between the layers of the lamina gastrica, giving off branches on either side, which anastomose freely in every direction. At the lower border of the omentum the trunks turn up again to meet the transverse arch of the colon, with the arteries of which intestine they form communications. The veins accompany the arteries in their course, and join the large venous trunks which end in the vena portarum. The few nerves it possesses are derived from the hepatic, and splenic plexuses.

The *appendices epiploicæ*, or *omentula*, are principally observed on the first parts of the great intestine, being in less number on the sigmoid flexure of the colon and the rectum. They are irregularly disposed, hanging in fringes, generally unconnected with each other, sometimes united by intermediate membranous productions. They are usually dependent from the pouches of the intestine, and not from the longitudinal bands. They are obviously formed by the peritoneal covering of the intestines, united by cellular membrane, and containing a deposit of fat in almost every instance.

The use of the omenta is entirely unknown: The lesser epiploon offers a covering, and connecting medium to some nerves belonging to the stomach, and to the hepatic vessels and ducts. To the great epiploon many offices have been ascribed, none of which are satisfactorily ascertained. It varies somewhat in size according to the state of the stomach; since, when the latter is distended, it appears to enter between the layers of peritoneum forming the anterior fold, which lose in this case their form of omentum, and become the temporary covering of this organ. What may be the probable advantages of this construction it is not easy to decide. It has been supposed again to secrete a lubricating fluid from its surface, which preserves the free motion of all the chylipoietic viscera between each other. That it increases the serous surface of the abdominal cavity is evident; but in what manner this becomes an advantageous disposition is more

than we have the means of determining. The omentum colicum, and appendices epiploicæ are subject to the same observations, being similar in structure, and consequently in uses. It is certain that a considerable portion of the great omentum may be cut away, without any subsequent inconvenience to the patient, as has been frequently observed in cases of omental hernia.

An epiploon is found in all the mammalia, where it is seen under every variety of form and size: so that no inferences can be drawn from its disposition in these particulars. In all it contains more or less of fat between its membranes, the accumulation of which would appear to bear some proportion to the active, or sluggish habits of the animal. In the hibernating species during the winter, it is loaded with fat, which exists but in minute quantities during the summer. The epiploon is not found in the other classes of animals, at least there is nothing analogous to it, but a membranous production between the liver and stomach, answering to the little omentum.

**EPIPLO'SCHEOCE'LE**, from *επιπλοου*, the omentum, *σσχειον*, the scrotum, and *κκλη*, a tumour, in *Surgery*, an omental rupture, situated in the scrotum.

**EPIPOGUM**, in *Botany*, *επι*, upon and *πογον*, a beard, because the beard, or rather lip, is turned upwards. Gmel. Sib. v. 1. 11. t. 2. f. 2. is *Satyrion Epipogium* of Linnæus; *Limodorum Epipogium* of Swartz and Willdenow. See **LIMODORUM**.

**EPIPOLÆ**, in *Ancient Geography*, was originally a piece of high ground without the city of Syracuse, and afterwards so little inhabited that it is not mentioned by Cicero in his description of this city. As it was the most elevated situation, and commanded Tyche and Neapolis, it was judiciously inclosed by Dionysius I., who encompassed it with a wall nearly 4 miles in extent. Its additional defence was the fortress of Labdalon, at its bottom, on the east; and that of Euryalus, at its top, on the north. See **SYRACUSE**.

**EPIPOMPEUTICA**, in the *Ancient Music*. Vossius, in his poetical institutes, informs us, that this was a title given to songs composed and sung on occasions of great magnificence.

**EPIPOROMA**, from *επιπρωρον*, to harden, in *Surgery*, a hard tumour on a joint: a tophus.

**EPIPROSLAMBANOMINOS**, *Gr.* in the *Ancient Music*, a name given to the string or sound below proslambanominos, which word corresponds with gamut in the Guido scale.

**EPIRE**, in *Geography*, an ancient kingdom of Greece, now united with Albania, and included in that country, of which it forms the southern part, extending from Valona to Arta.

**EPIROTS**, in *Ancient Geography*. See the next article.

**EPIRUS**, a country of Greece, bounded on the east by Ætolia, on the west by the Adriatic, on the north by Thessaly and Macedon, and on the south by the Ionian sea. This was the ancient kingdom of the Æacidae, and was first called "Epirus Dodonæa," *i. e.* the continent of the Dodonæans, and afterwards Epirus, or "the continent," that being the import of the Greek word *Επειρος*. It was anciently divided into three districts or provinces; *viz.* Chaonia, Thesprotia, and Molossis; to which some authors add Cassopia, Cassiope, or Cæstrine, and Pindus. This country is said to have been first peopled by Dodanim, the son of Javan, and grandson of Japhet, or at least by some of his posterity. We find among the nations which occupied Epirus, before they were united into one people under the common name of Epirots, the Selli, who are thought to have been the

first inhabitants of Epirus, and to have ministered in the temple of Dodona, the Chaones, the Molossi, the Dolopes, the Dryopes, the Ænians, the Pelasgi, &c. The form of government which prevailed in Epirus was unquestionably monarchical, the whole country being divided into many small independent kingdoms. Homer, and other ancient writers, mention several kings who reigned here at the time of the Trojan war. But while the other Epirotic nations continued to be governed by princes of their own blood, the Molossi became subject, at an early period, to the power of Pyrrhus, a foreign prince, whose descendants were denominated Æacidæ, from Æacus, the founder of his family. Some of these petty kingdoms, in process of time, exchanged the monarchical into a republican form of government; for Thucydides informs us, that in his time the Theprotæ and Chaones were governed, not by kings, but by annual magistrates. However, the kingdom of the Molossi soon eclipsed all others; the Molossian princes having subjected the whole country, and united the several small kingdoms of which it consisted into one, known to the ancients under the name of Epirus.

Pyrrhus, the first of the Æacidæ, was the sovereign of this country at the period when regular and authentic history commences; and he is said to have distinguished himself at the siege of Troy, when his father was killed. His reign soon terminated by a premature death; for he was murdered by Orestes in the temple of Delphi, on account of his having married Hermione, the daughter of Menelaus, who had been betrothed to Orestes. He was succeeded by his son Molossus, and several other princes, whose names it is needless to record. At length Admetus was the sovereign of Epirus, when Xerxes invaded Greece. This prince, upon the defeat of the Persians, wished to enter into an alliance with the Athenians, about the year 478 or 479 B. C. The successors of Admetus were Tharymbas, who is said to have introduced the sciences into this country, and to have formed an excellent code of laws; and Alcetes, at whose death the kingdom was divided between his two sons, Neoptolemus and Arybas, the latter of whom, when his brother died, became sole sovereign of the country, and conducted the government with great prudence, equity, and moderation. He also encouraged literature by extending his patronage to those who excelled in it. His niece Olympias, of whose education he had taken great care, was married to Philip, king of Macedon, who had by her Alexander the Great. At his death, he was succeeded by Alexander, one of his nephews; who is said to have been little inferior, in courage and conduct, to his nephew Alexander the Great; but he had the misfortune to engage, on his first setting out, with nations inured to the toils of war, and no less brave than his own Epirots; whence he used to say, that the country, which he proposed to conquer, was inhabited by men, whereas the provinces his nephew Alexander went to subdue, were peopled by women only. (Aul. Gell. l. xvii. c. 21.) The immediate successors of Alexander were Æacides and Alcetes II.; and the latter was succeeded by Pyrrhus, descended by the father from Achilles, and from Hercules by the mother. (See PYRRHUS.) After two or three short reigns, Deidamia, great grand-daughter to Pyrrhus, succeeded her father Pyrrhus III. and having no issue, she gave the Epirots their liberty, who formed themselves into a republic, which was governed by magistrates annually elected in a general assembly of the whole nation. The Macedonians on one side, and the Illyrians on the other, taking advantage of the intestine divisions, which generally attend a popular government, seized on several provinces belonging to the Epirots, and annexed them to their respect-

ive crowns. The Romans, after having conquered Philip of Macedon, restored them to their ancient liberty; but they ungratefully took up arms against their benefactors, and joined Perseus; which induced the Romans to send orders to Paulus Æmilius, after the reduction of Macedon, to plunder their cities and level them with the ground. This order was punctually, though reluctantly, executed throughout the whole country in one day. One hundred and fifty thousand of the inhabitants were made slaves, and sold to the best bidder for the benefit of the republic. All the cities of Epirus, to the number of 70, were dismantled, and the chief men of the country carried to Rome, where they were tried, and most of them condemned to perpetual imprisonment. After this catastrophe, Epirus never recovered its ancient splendour. Upon the dissolution of the Achæan league, it was made part of the province of Macedon; but when Macedon became a diocese, Epirus was made a province of itself, called the province of Old Epirus, to distinguish it from New Epirus, another province lying to the east of it. On the division of the empire, it fell to the emperors of the east, and continued under them till the capture of Constantinople by the Latins, when Michael Angelus, a prince nearly related to the Greek emperor, seized on Ætolia and Epirus. He was succeeded by his brother Theodorus, who so far enlarged his dominions, that, disdaining the title of despot, he assumed that of emperor, and was crowned by Demetrius archbishop of Bulgaria. Charles, the last prince of this family, dying without lawful issue, bequeathed Epirus and Acarnania to his natural sons, who were expelled by Amurath II. Great part of Epirus was afterwards held by the noble family of the Castriots, who, though they were masters of all Albania, yet styled themselves princes of Epirus. Upon the death of the famous George Castriot, Epirus fell to the Venetians, who were soon dispossessed of it by the Turks, in whose hands it still continues; being now known by the name of Albania, which comprehends the Albania of the ancients, all Epirus, and that part of Dalmatia which is subject to the Turks. Plutarch tells us, that the Epirots enjoyed the best sort of liberty under their kings; for, as he says, a general assembly of the people was annually convened at Passaron, a city in the province of Molossis, where the king bound himself by a solemn oath to govern agreeably to the laws, and the people to obey and support him as long as he should make the laws the rule of his government.

EPISARCIDIUM, from ἐπι and σαρξ, *flesh*, a name given by many of the old authors to an anasarca.

EPISCAPHIA, from ἐπι and σκαφη, *boat*, feasts celebrated by the Rhodians.

EPISCENIA, from ἐπι and σκηνη, *tent*, feasts celebrated by the Lacedæmonians.

EPISCENIUM, Ἐπισκηνιον, in *Antiquity*, a place upon the top of the theatre, where all the machines for moving the scenes were kept. Potter. Archæol. Græc. lib. i. cap. 8. p. 42.

EPISCEPSIS, Ἐπισκεψις, an action brought to prove the diamartyria, or protestation, that the person deceased had left an heir, to be false and groundless. Potter. Archæol. Græc. lib. i. cap. 24. i. p. 128.

EPISCIRA, Ἐπισκίρα, or EPISCIROISIS, a festival celebrated at Scira in Attica, in honour of Ceres and Proserpine. Potter. Archæol. Græc. lib. ii. cap. 20. tom. i. p. 395.

EPISCHESES, from ἐπιχω, or ἐπισχω, *I restrain*, in *Medicine*, a term used by Dr. Cullen to denote the fifth order of his fourth class of diseases, which includes the retention

tention of accustomed evacuations, *viz.* constipation of the bowels, suppression of urine, of the catamenia, &c.

EPISCHION, from *επι* and *ισχιον*, *ischium*, a name given by the old Greek writers to the pubes.

EPISCOPACY, the quality of episcopal government, or that form of church discipline, wherein diocesan bishops are established, distinct from, and superior to, priests or presbyters. See BISHOP, EPISCOPAL, EPISCOPALIANS, and HIERARCHY.

Episcopacy, and presbytery, have been alternately established and abolished in Scotland.

EPISCOPACIDE, from *επισκοπος*, *bishop*, and *caedo*, *I kill*, the crime of murdering a bishop by one of his own clergy. By the ancient laws of England, the same obedience is due from a clergyman to his bishop as from a servant to his master; and therefore the offences of murdering either are made equal, that is, they are both petty treason.

EPISCOPAL, something that belongs to a bishop.

The word is formed of the Greek *επισκοπος*, *overseer*, derived from *επισκοπειν*, *inspicio*, *I inspect*, or *overlook*.

Episcopal government, is the government of a diocese, wherein one single person, legally consecrated, presides over the clergy of a whole district, in quality of head, or superintendent thereof; conferring orders, and exercising a sort of jurisdiction.

The presbyterians reject the episcopal establishment, and condemn the episcopal orders as a human institution, the mere result of secular policy, or of pride and ambition.

Among the episcopal functions, the principal part is that of holding frequent visitations of the diocese.

EPISCOPALES VALVULÆ, called also, by some, *valvulæ mitrales*, two valves in the pulmonary vein, which prevent the reflux of the blood to the heart.

EPISCOPALIA, is sometimes used in the same sense with pontificalia.

EPISCOPALIA, is also used to denote synodals, or customary payments, due to the bishops from the clergy of their diocese.

These customary payments have been otherwise called *onus episcopale*; and were remitted, by special privilege, to free churches and chapels of the king's foundation which were exempt from episcopal jurisdiction.

EPISCOPALIANS, or EPISCOPISTS, a name given to those who adhere to the church of England, and particularly to the ecclesiastical hierarchy, such as it was in the Romish church before the Reformation; who affect the discipline of bishops, priests, canons, the office, or liturgy, &c. and retain the greatest part of the canon law, with the decretals of the popes, more closely than the Catholics themselves of several countries; though, as to matters of doctrine, or faith, they agree in most points with the Calvinists, or Reformed.

In Scotland, the principal dissenters are the Episcopals; lay Episcopals enjoy all the same civil privileges with those of the established church. They are under no restrictions; tied to no tests, but are employed in all places of trust, upon taking the oaths to the government. But the episcopal ministers are liable to several penal laws; many of them having been nonjurors.

EPISCOPI MULTA. See MULTA.

EPISCOPISSA, a word used by writers of the middle ages, to denote a bishop's wife.

EPISCOPIUS, SIMON, in *Biography*, a Dutch divine of the Arminian persuasion, was born at Amsterdam in the year 1583. Having entered on his academical studies in the university of Leyden in 1600, and graduated M. A. in

1606, he pursued his theological studies with great assiduity; but on account of the disputes that subsisted between the Gomarists and Arminians, he found obstacles in the way of his admission to the ministerial office, which the burgomasters of Amsterdam wished him to assume. Disgusted by this illiberal treatment, he left Leyden in 1609, and removed to the university of Franeker, where he had to contend with similar difficulties, on account of his attachment to the Arminian doctrines. In the year 1710, however, he was admitted to the profession of the ministry, and appointed to a church at Bleswyck, in the neighbourhood of Rotterdam. In the following year he appeared as one of the deputies at the conference held at the Hague, before the states of the province, between six anti-remonstrant and six remonstrant ministers, where he distinguished himself by his defence of the opinions of his party. In 1712 he was chosen professor of divinity at Leyden, in the room of Gomarus, who surrendered that office. In this situation he conducted himself with singular prudence, as well as ability, so that he lived on terms of amity with Polyander, his colleague, who belonged to the party of Gomarists. The controversy concerning predestination was at this time the occasion of great animosity; and Episcopius, and his friends, were objects of enmity and persecution to the deluded populace. Their condition was rendered more perilous by the partisans of Maurice, prince of Orange, by whom they were calumniated, not only as heretics in their theological sentiments, but as enemies to the protestant religion, and to the United Provinces. At length Maurice and the Gomarists, of whom he was the head, succeeded in obtaining a decree of the States for convening a national synod; but the Arminians remonstrated against the meeting of such a synod, because they well know that it would be composed of their inveterate enemies, who on this occasion would appear both as their accusers and their judges. However, it met at Dort in the year 1618, (See *Synod of Dort*.) and the business of the sessions was conducted as Episcopius and his party apprehended. The ruling members were invincible, and required implicit submission to their decisions. It was in vain that Episcopius and his brethren demurred and remonstrated against their proceedings. They were expelled from the synod, and their cause was tried during their absence. The result was a sentence, which charged them with pestilential errors, and with being corrupters of the true religion. This sentence was followed by their excommunication, a deprivation of their offices, ecclesiastical and civil, a prohibition to exercise their ministry, and besides fines and imprisonment, banishment from the territories of the republic. Accordingly Episcopius, as well as several of his adherents, retired to Antwerp, where he drew up various publications in defence of his oppressed party, some of which are, "A Confession of Faith," expressed for the most part in words and phrases of scripture; a treatise, entitled "Antidotum adversus Synodi Dordracenæ Canones," and two letters, addressed to Wadingus, a Jesuit, who wished to seduce him into his church, one on the rule of faith, and the other upon the worship of images. In 1609, Episcopius withdrew into France, and endeavoured to confirm and comfort his brethren, as well as to diffuse the opinions for which he suffered, both by his correspondence and publications. In 1626, after the death of prince Maurice, and the accession of prince Frederick Henry, he returned to his native country, and enjoyed the benefits of toleration and tranquillity. The place of his settlement was Rotterdam, where he exercised his ministry for about 8 years, and composed several pieces of a theo-

logical

logical and controversial nature, which were published during his life and after his death. The Arminians, having remained for some years unmolested, established a college at Amsterdam, of which Episcopius was the first theological professor, and this appointment occasioned his removal to Amsterdam in the year 1634. In the honourable and diligent discharge of the duties of this office, he continued till his death, which happened in 1643. Episcopius was a man of solid and extensive learning; a cool and accurate judgment, a lively genius, and commanding powers of eloquence. His controversial pieces, though occasionally intermixed with unbecoming ardour and bitterness, are generally distinguished by a spirit of candour and moderation. His character was highly exemplary. His sentiments coincided with those of Arminius, which he reduced into a systematic form, and recommended by the graces of composition. His works, consisting of commentaries, theological institutions, controversial treatises, &c. form two volumes in folio; which were edited by Peter Curcellæus, who has prefixed an account of the author. A larger life of him was published by Philip à Limborch, the son of his brother's daughter, written in the Dutch language, of which a Latin version appeared at Amsterdam in 1701. 8vo. Bayle. Mosheim. Moreri. Gen. Biog.

**EPISCOPUS PUERORUM**, *bishop of the boys*, a ludicrous kind of office, formerly exercised in churches, in that called the feast of fools, or the feast of the kalends. See *Boy BISHOP*.

**EPISEMASIA**, from *επισημασιω*, *I signify*, in *Medicine*, is the very time that a disease first seizes a person, and is properly called *significatio*. Blancard.

**EPISODE**, *Επισοδιον*, from *επι*, *upon*, and *εισοδος*, *entry*, is commonly conceived to be a separate incident, story, or action, which an historian, or poet, inserts, and connects with his principal action; to furnish out the work with a greater diversity of events; though, in strictness, all the particular incidents whereof the action or narration is composed, are called episodes.

**EPISODE**, in *Dramatic Poetry*, was the second part of the ancient tragedy.

The origin and use of episodes is described by M. Hederlin, and F. Bossu. Tragedy, in its original, being only a hymn sung in honour of Bacchus, by several persons, who made a kind of chorus, or concert of music, with dancing, and the like; to diversify the representation a little, and divert the audience, they determined at length to divide the singing of the chorus into several parts, and to have something rehearsed in the intervals.

At first, a single person, or actor, was introduced, then two, then more; and what the actors thus rehearsed, or entertained the audience with, being something foreign, or additional to, or beside, the song of the chorus, and no necessary part thereof, was called *επισοδιον*, *episode*.

And hence tragedy came to consist of four parts, the prologue, episode, exode, and chorus. The prologue was all that preceded the first entrance of the chorus, and concluded with the first interlude, or choral ode, between the acts. The episode, all that was interposed between the singings of the chorus, and extended in general from the first to the last of the interludes. The exode, all that was rehearsed after the chorus had done singing, or comprehended all that was said after the last interlude. And the chorus, was the *grex*, or company, that sung the hymn. See each of these articles.

And as this recitation of the actors was in several parts, and inserted in several places, it might either be considered

together as a single episode, consisting of several parts; or each part might be called a distinct episode.

These several episodes in the same tragedy might either be taken from so many different subjects, or from the same subject divided into a proper number of recitations, or incidents.

To consider only the first occasion, and institution of these foreign or additional pieces, it appears no ways necessary, that they should be taken from one and the same subject; three or four recitations of different actions, no wise related, or connected to each other, would ease the actors, and amuse the people, in the intervals of the chorus, as well as if they were all so many parts of the same action. By degrees, what was at first only an addition to the tragedy, became the principal part thereof. Then the several pieces, or episodes, began to be considered as one single body which was not to have parts, or members of different nature, and independent of each other.

The best poets took the thing in this light, and drew all their episodes from the same action; which practice was so fully established in Aristotle's time, that he lays it down as a rule. Those tragedies wherein this unity and connexion were not observed, he called *episodic pieces*. See *TRAGEDY*.

**EPISODE**, in *Epic Poetry*. The term episode, by being transplanted from the stage to the *epopœia*, did not change its nature. All the difference Aristotle makes between the tragic and epic episodes, is, that the latter are more ample than the former.

Aristotle uses the word in three different senses: the first taken from the enumeration already made of the parts of the tragedy, *viz.* prologue, chorus, episode, and exode; whence it follows, that in tragedy, every thing is episode that is none of the other parts; so that as, among us, there are tragedies without either prologue, chorus, or epilogue, the tragic episode includes the whole tragedy; consequently the epic episode must be the whole poem, in like manner; all there is to retrench from it being the proposition and invocation, which stand in lieu of the prologue. In this sense, the *epopœia* and tragedy have each only one episode; and if the parts or accidents be ill connected together, the poem will be episodic and defective.

But farther, as all that was sung in the tragedy was called the chorus, in the singular number, yet this singularity did by no means prevent every part or division of the same from being called a chorus, without making several chorusses; so it was with the episode; each incident, and part of the fable and action, is not only a part of the episode, but it is an episode itself.

The term episode, therefore, in this sense, signifies every part of the action expressed in the plan, or first draught of the fable; as the absence and wanderings of Ulysses, the disorders in his family, and his presence, which retrieved and set all to rights again.

Aristotle furnishes us with a third kind of episode; in shewing that what is contained and expressed in the first plan of the fable is proper, and that all the rest is episode.

By *proper* he means what is absolutely necessary; and by episode, what in one sense is necessary, and in another not; so that the poet is at liberty to use, or let it alone.

Thus, Homer, having made the first draught of the fable of his *Odyssæy*, was not at liberty either to make Ulysses absent from his country, or not. His absence was essential; and therefore Aristotle ranks it among the things he calls *proper*. But he does not bestow that appellation on the adventures of Antiphates, Cice, the Sirens, Scylla, Charybdis,

Charybdis, &c. The poet was at liberty to have left these alone, and to have chosen others in their room; so that they are episodes distinct from the first action, to which they are not immediately necessary.

The third sense of the word episode comes to the second: all the difference between them is, that what we call episode in the second sense, is the ground or plan of the episode in the third; and that the third adds to the second certain circumstances which are only probable, and not necessary, as the places, princes, and people, among whom Ulysses was cast by Neptune.

It must be added, that in an episode in the third sense, the incident, or episode in the first sense, whereon it is grounded, is to be extended and amplified; otherwise, an essential part of the action and fable does not become an episode.

Lastly, it is in this third sense that we are to understand that precept of Aristotle, not to make the episodes till after the names of the persons have been chosen. Homer would not have spoken of the fleets and ships as he has done, if, in lieu of the names of Achilles, Agamemnon, and Iliad, he had chosen those of Adrastus, Capaneus, and Thebaid.

Upon the whole, the term episode, in the epic poem, as used by the father of the critics, Aristotle, does not signify any foreign or accidental adventure; but the whole narration of the poet, or a necessary and essential part of the action and subject, amplified with probable circumstances.

Thus Aristotle enjoins that the episode be not added to the action, or fetched from elsewhere; but that it be a part of the action; and never uses the word *adding*, in speaking of episodes, though it occurred so naturally to his interpreters, that they have generally used it in their translations and comments. He does not say, that after laying the plan and choosing the names, the poet is to add the episodes; but uses the derivative of the word episode, *επισοδον*, as if in English we should say epifodify his action.

From what has been said, we may venture to define episodes to be necessary parts of the action, extended and filled up with probable circumstances. Now an episode is only a part of an action, and not a whole action; and this part of the action, which is the base or ground of the episode, must not, when epifodified, retain any thing of the simplicity which it had when first expressed in general, in the plan of the fable.

The subject of a poem may be lengthened two ways; either by the poet's making use of a great many of his episodes; or by his amplifying and giving a greater extent to every one. By this latter method, chiefly, it is, that the epic poets lengthen their poems much beyond the dramatic. It must be added, that there are certain parts of an action, which of themselves do not naturally present or afford more than one episode; such as the death of Hector, of Turnus, or the like: whereas there are other parts of the fable more copious and fertile, and which oblige the poet to make diverse episodes on each, though laid down in the first plan with as much simplicity as the rest: such are the battles of the Trojans and Grecians, the absence of Ulysses; the wanderings of Æneas, &c. For Ulysses's absence so many years from his own country, required his presence elsewhere; and the design of the fable was to throw him into several dangers, and different countries. Now each peril, and each new country, furnished an episode, which the poet might use if he pleased.

The result of the whole is, that episodes are not actions, but parts of actions; that they are not added to the action and matter of the poem, but make the action and matter

themselves; that of course they are not to be fetched from elsewhere, but raised from the ground or basis of the action; that they are not united and connected with the action, but with one another; that all the parts of an action are not so many episodes, but only such as are amplified, and attended with particular circumstances; and lastly, that their union with each other is necessary in the ground of the episode, and probable in the circumstances.

Episodes, says Dr. Blair, (Lectures. vol. iii.), as the term is now understood, are certain actions, or incidents, introduced into the narration, connected with the principal action, yet not of such importance as to destroy, if they had been omitted, the main subject of the poem. Of this nature are the interview of Hector with Andromache, in the Iliad; the story of Cacus, and that of Nisus and Euryalus in the Æneid; the Adventures of Tancred with Erminia and Clorinda, in the Jerusalem; and the prospect of his descendants exhibited to Adam, in the last books of Paradise Lost. Such episodes as these, are not only permitted to the epic poet; but, provided that they be properly executed, are great ornaments to his work. The rules that serve to regulate them are such as follow: they must be naturally introduced, and have a sufficient connection with the subject of the poem; they must seem to be inferior parts belonging to it, and not mere appendages annexed to it. In the next place, episodes ought to present to us objects of a different kind, from those which go before, and those which follow, in the course of the poem. For episodes are introduced into an epic composition, principally for the sake of variety. Lastly, as an episode is a professed embellishment, it ought to be particularly elegant and well-finished; and, accordingly, it is, for the most part, in pieces of this kind, that poets put forth their strength. The episodes of Taribezus and Ariana, in Glover's Leonidas; and of the death of Hercules, in the Epigoniad, are the two greatest beauties in these poems. With regard to episodes in didactic poetry; see DIDACTIC Poetry.

EPISODIC, in Poetry. A fable is said to be epifodic, when it is swelled with unnecessary incidents; and its episodes are not necessarily, nor properly, connected with each other.

Aristotle lays it down, that those tragedies are most defective, whose episodes have no connection, or dependence on each other, which he calls epifodic, *q. d.* superabundant in episodes; because so many little episodes can never compose one whole one, but necessarily remain in a vicious plurality.

If an episode be used, the names and circumstances whereof are unnecessary, and whose ground and subject make no part of the action, that is, of the matter of the poem, such an episode renders the fable epifodic. This irregularity is discovered, when one may take away a whole episode, without substituting any thing in its room; and yet leave no chasm, or defect, in the poem. The history of Hyppisule, in Statius's Thebaid, affords an instance of these faulty episodes. If the whole story of that illustrious nurse were retrenched, the sequel of the principal action would be the better for it. Nor would any body imagine he had forgot any thing, or that there was any member of his action wanting. Bossu, and Arist. Poet. cap. 9.

EPISPASTIC, from *επι* and *σπάω*, *I draw*, in Medicine, a term denoting the quality of those substances, which, when applied to the skin, draw the humours to the part, or excite inflammation and vesication in it. The word, therefore, is nearly synonymous with vesicatory, or blistering. See BLISTER.

**EPISPHERIA**, from *σφαῖρα* and *σφαιρα*, a sphere, in *Anatomy*, are windings and turnings in the outer substance of the brain, that the sanguiferous vessels may pass more securely.

**EPISTÆBE**, in *Botany*, a name given to the cuscuta or dodder, found growing on the plant stæbe of the ancient Greeks. See **ΕΠΙΦΥΕΙΟΣ**.

**EPISTAPHYLINUS**, in *Anatomy*, a name under which the azygos uvulæ muscle has been described. It will be found, in different writers, under the names of staphylinus, columellæ musculus teres, musculus uvulæ, or muscle de la luette. It is described in the article **DECLUTITION**.

**EPISTATES**, *Επιστάτης*, derived from *επι*, over, and *στημι*, I stand, in *Antiquity*, a person who has the command and direction of an affair, or of a people.

The term is of considerable use, in speaking of the government of Athens, where the epistates was the senator in command for that day, or whose turn it was to preside that day. The constitution was this: the ten tribes of Athens formed by Clithenes, elected every year by lot, each of them, fifty senators, which made a senate of five hundred. Every tribe had the precedence in its turn, and surrendered it again successively to another. The fifty senators in office were called prytanes; the particular place where they assembled, prytaneum, and the term, or duration of their office, viz. thirty-five days, prytanea. During these thirty-five days, ten of the fifty prytanes presided weekly, under the name of proedri; and of these proedri there was one to preside each day of the week, under the title of epistates.

No person was allowed to hold his office more than once in his whole life, lest he should acquire too much the taste of dominion: the senators of all the other tribes still voted, according to the order the lot had given them; but the prytanes laid the business before them, and the epistates took their votes and opinions.

It must be added, that of the ten proedri, of each week, there were but seven that would preside each his day in the quality of epistates; the ten proedri elected the seven prytanes.

**EPISTA'XIS**, from *επιστάζω*, *insillio*, in *Surgery*, hemorrhage from the nose.

When bleeding from the nose takes place in such a degree as to be dangerous, or likely to bring on excessive debility, the further effusion of blood may be stopped in the following manner. Roll a considerable piece of lint round the end of a probe; wet it completely through with a strong solution of the zincum vitriolatum; introduce it into the nostril, and press it as strongly as possible against the part whence the blood issues. As soon as the blood ceases to flow, we may conclude that the pressure acts on the bleeding point. This plan generally succeeds.

When the blood, however, flows from some point which lies very deeply in the nostril, it might be found impracticable to make pressure exactly on the bleeding vessels. At all events, we may then pass a piece of catgut through the nostril, and bring it out of the mouth, from the fauces, by means of a pair of common forceps. A tent of lint may next be fastened to the ligature, and drawn backward through the mouth into the nose, so as completely to stop up the posterior opening of the nostril. The front aperture may be easily filled with a proper dossil of lint. In this manner, it is clear that no further hemorrhage can happen, as the blood cannot possibly find its way outward.

**EPISTEMONARCH**, derived from *επιστημοναρχος*, *know-ledge*, and *αρχη*, command, a dignitary, in the *Ancient Greek Church*, appointed to watch over the actions of the church,

and to inspect or superintend every thing relating to the faith, in quality of a censor. His office answered pretty much to that of magister sacri palatii at Rome.

**EPISTHOTONOS**, from *επισθω*, forwards, and *τυνα*, to extend, in *Surgery*, a species of tetanus, in which the body is bent forwards. See **TETANUS**.

**EPISTITES**, from *επιστημι*, I keep off, in *Natural History*, the name of a stone, described by the writers of the middle ages, as being of a beautiful red, and shining very elegantly. It was renowned for its many magical virtues, according to the idle tradition of these times; they said it drove away all noxious animals, and kept off storms from the place where any one was who had it about him.

**EPISTLE**, a letter missive.

The word is formed of *επιστηλλω*, I send.

The term epistle is now scarcely used, but for letters wrote in verse, and letters dedicatory.

In speaking of letters written by moderns, or rather in the modern languages, we never use the word epistle. Thus, we say, the letters, not epistles of the cardinal D'Osiat, of Voiture, of Balzac, of Howel, of Pope, &c.: but those wrote by the ancients, or rather in the ancient language, we call epistles; as the epistles, not letters in Cicero, Pliny, Seneca. The epistles of St. Paul, St. Peter, St. John, &c. to the Romans, Corinthians, &c.

A Table of St. Paul's Epistles, in the order of time, with the places where, and the times when they were written.

Epistles.	Places.	A. D.
1 Thessalonians	Corinth	52
2 Thessalonians		
Galatians	Corinth, or Ephesus	Near the end of 52 or the beginning of 53
1 Corinthians	Ephesus	
1 Timothy	Macedonia	The beginning of 56
Titus	Macedonia, or near it	Before the end of 56
2 Corinthians	Macedonia	About October 57
Romans	Corinth	About February 58
Ephesians	Rome	About April 61
2 Timothy	Rome	About May 61
Philippians	Rome	Before the end of 62
Colossians	Rome	Before the end of 62
Philemon	Rome	Before the end of 62
Hebrews	Rome, or Italy	In the spring of 63

A Table of the Seven Catholic Epistles, so called because they were written to Christians in general, and the Revelation, with the places where, and the times when they were written.

Epistles.	Places.	A. D.
The Epistle of St. James	Judea	61 or beginning of 62
The 2 Epistles of St. Peter	Rome	64
St. John's 1st Epistle	Ephesus	About 80
His 2d and 3d Epistles	Ephesus	Between 80 and 90
The Epistle of St. Jude	Unknown	60 or 65
The Revelation of St. John	Patmos, or Ephesus	95 or 96

See Lardner's Credibility of the Gospel History, vol. xvi. and vol. xvii.

Learned writers are not absolutely agreed as to the dates of these several epistles, nor the places whence they were written. It would lead us too far to examine and produce the various authorities and arguments that have been used for settling these particulars: we shall only mention that Dr. Doddridge dates the 1st Epistle to the Corinthians

about the year 57; and the 2d Epistle in 58; those to the Ephesians, Philippians, Colossians, and Philemon, in 63; the 1st to Timothy, in 58 or 65; the 2d to Timothy, in 66 or 67; the Epistle to Titus, between St. Paul's first and second imprisonment at Rome; the Epistle of St. James, in 60 or 61; the 1st of Peter in 61; the 2d, in 67; that of St. Jude, some time after the 2d of Peter, according to Dr. Mills, in the year 90. As to the general design of these several epistles, it is observed by Dr. Doddridge, who is deservedly esteemed an excellent and useful expositor, that the Epistle to the Romans is intended to fix in the minds of the Christians, to whom it is addressed, a just sense of the excellency of the gospel, and to engage them to act in a manner agreeable to their profession of it: the Epistles to the Corinthians are designed to resolve some important queries proposed by them, and to correct the various criminal irregularities and disorders, of which they were guilty: the principal design of the Epistle to the Galatians was to assert and vindicate the apostle's authority and doctrine, and to confirm the churches of Galatia in the faith of Christ, especially with respect to the important point of justification; to expose the errors that were introduced among them, and to revive those principles of Christianity which he had already taught them. In the Epistle to the Ephesians, that apostle endeavours to establish them in the faith; and to this end to give them more exalted views of the divine love and the excellence of Christ; to shew them that they were now, though Gentiles, made partakers of equal privileges with the Jews; to encourage them, by his own example and concern for their welfare; and to engage them to the practice of duties becoming their Christian character. The Epistle to the Philippians is designed to comfort them under the concern they felt on his account; to check a party-spirit that had broke out among them, and to promote union and affection; to guard them against the seduction of judaizing teachers; to support them under their trials, and to inspire them with an ambition of excelling in ornamental and distinguished attainments. The Epistle to the Colossians is designed to excite them to a temper and conduct worthy of their sacred character, and to secure them from the influence of those Pagan sophists or Jewish bigots, who endeavoured to seduce them from the purity of the Christian faith. The two Epistles to the Thessalonians are intended to confirm them in their adherence to the Christian faith, and to engage them, from the sufferings they had already endured, and the extraordinary character they had hitherto maintained, to make great advances, and to excel still more in religion and virtue; and also to rectify some erroneous apprehensions they entertained about the coming of Christ, and to direct them in the proper exercise of Christian discipline. The first Epistle of Timothy was partly intended to direct him in managing the affairs of the church, and choosing proper persons for the various offices it required; and partly to caution him against the influence of judaizing teachers, to urge him to pay a constant regard to the interests of practical religion, and to animate him to diligence, fidelity, and zeal. The second epistle prepares Timothy for the sufferings that awaited him, forewarns him of the apostacy that was beginning to appear in the church, and animates him to the persevering discharge of every part of the ministerial office. The Epistle to Titus contains a variety of prudent instructions and cautions. The design of the Epistle to the Hebrews was to confirm the Jewish Christians in the faith and practice of the gospel, which they might be in danger of deserting through the insinuation or ill-treatment of their persecutors. St. James, in his epistle, aims to correct these errors both in doctrine and

practice into which the Jewish Christians had fallen, which might otherwise have produced fatal consequences; and then to establish the faith, and animate the hope of sincere believers under their present and approaching sufferings. The Epistles of St. Peter are designed to induce the Christian converts in various parts of the world to maintain a conduct inoffensive and amiable; to support them under their trials, and to encourage their constancy, notwithstanding the artifices of false teachers, and the persecution of their most inveterate enemies. The leading design of St. John in his first epistle, is to evince the vanity of faith separate from morality; to inspire the minds of Christians with mutual charity, and to guard them against the snares and efforts of Antichrist, and of all who were endued with his spirit. The Epistle of Jude describes the characters of the false teachers, represents the divine judgments which such persons had reason to expect, and thus cautions Christians against being perverted by them. See Doddridge's Fam. Expositor, vol. iv. v. and vi. in the general introduction prefixed to each epistle. See also an account of the writers of these epistles, and of the churches to which they were addressed.

EPISTLE, *Poetical*, a species of didactic poetry, the subjects of which are the manners and characters that occur in ordinary life, and that require to be treated with somewhat of the ease and freedom of conversation. When these epistles are employed on moral and critical subjects, they seldom rise into a higher strain of poetry than *satires*, which see. Many other subjects may be discussed in the form of an epistle; such as love poetry, or elegiac; specimens of which occur in Ovid's "*Epistolæ Heroidum*," and his "*Epistolæ de Ponto*." As these works are designed to be merely sentimental, and their merit consists in being proper expressions of the passion or sentiment which forms the subject, they may assume any tone of poetry that is suited to it. But didactic epistles seldom admit of much elevation. The poet, commonly restricting himself to observations on authors, or on life and characters, and not intending to compose a formal treatise, or to confine himself strictly to regular method, gives scope to his genius on some particular theme, which, at the time, has prompted him to write. Much of the grace of this kind of writing consists in a spirited conciseness, which gives to such composition an edge and liveliness, that strike the fancy and keep attention awake. Much of their merit depends also on just and happy representations of characters. Unsupported by those high beauties of descriptive and poetical language, which adorn other compositions, the reader expects them to entertain him with lively paintings of men and manners; and therefore in these a certain sprightliness and turn of wit find their proper place, and contribute to the beauty and effect. Of this kind of poetry Mr. Pope's ethical epistles furnish an almost perfect model. In these his wit discovers itself to such a degree as to give a proper seasoning to grave reflections. His paintings of characters are natural and lively; and, never was any writer so happy in that concise spirited style, which gives animation to satires and epistles. His rhyme likewise adds to the style an elevation which otherwise it could not have possessed, while at the same time he manages it so artfully, that it never appears in the least to incumber him, but, on the contrary, serves to increase the liveliness of his manner. In this species of writing, ease and elegance are the distinguishing characters; nothing, therefore, should be forced or unnatural, laboured or affected, but every part of the composition should manifest an easy, polite, and unconstrained freedom.

EPISTOLARES, among the Romans, under-secretaries.

ries to the "magister scrinii epistolarum," or secretary who wrote the emperor's letters. They were thirty-four in number. See **MAGISTER**.

**EPISTOLARY**, a term used in the phrase epistolary style. As the matter of an epistle is the same with that of conversation, it should not differ in the manner of expression; and, therefore, all pomp and study of language are not only needless but very improper: the most plain and easy way of conveying our thoughts must certainly be best, as being most natural. Purity in the choice of words, and justness of construction, joined with perspicuity, are the chief properties of this style: to which purpose Cicero observes, "that in writing letters we make use of common words and expressions." (Ad Fam. lib. ix. cap. 21.) And Seneca says, "I would have my letters be like my discourses, when we either sit or walk together, unstudied and easy." (Ep. 75. ad Lucill.)

The first and fundamental requisite in epistolary writing is to be natural and simple, for a stiff and laboured manner is as bad in a letter as in conversation. This does not banish sprightliness and wit. These are graceful in letters as well as in conversation; when they flow easily, and without being studied; when employed so as to season, and not to clog. A person, who either in conversation or in letters affects to shine and sparkle always, will not please long. The style of letters should be neat and correct, but not too highly polished. Nicety about words betrays study; and on this account musical periods, and appearances of number and harmony in arrangement, should be carefully avoided in letters. Those that are written with the greatest facility are commonly the best. Nevertheless, it should be remembered, that the ease and simplicity of epistolary writing are not to be understood as importing entire carelessness. In writing to the most intimate friend, a certain degree of attention, both to the subject and the style, is requisite and becoming. The first requisite both in conversation and correspondence, is to regard all the proper decorums, which our own character, and that of others demand. An imprudent expression in conversation may be forgotten and pass away; but with the pen in hand, we should remember the well-known adage, "Litera scripta manet."

As the subjects of epistles are various, they will necessarily acquire some variety in the manner of expression. If the subject be weighty and momentous, the language should be strong and solemn; in things of a lower nature, more free and easy; and upon lighter matters, jocose and pleasant. In exhortations, it ought to be lively and vigorous; in consolations, kind and compassionate; and in advising, grave and serious. In narratives, it should be clear and distinct; in requests, modest; in commendations, friendly, without adulation; in prosperity, cheerful; and mournful, in adversity. In a word, the style ought to be accommodated to the particular nature of the subject about which it is conversant. Although there should be nothing very considerable in the subject; yet if the spirit and turn of the correspondence be agreeable, if the letters be written in a sprightly manner, and with native grace and ease, they may still be entertaining, more especially if there be any thing to interest us in the characters of those who write them. As letters from one friend to another make the nearest approach to conversation, we may expect to see more of character displayed in these than in other productions, which are studied for public view. We are pleased with beholding a writer so situated as to allow him to be at his ease, and to give occasional vent to the overflowings of his heart. Besides, the different character of the person, to whom the letter is written, requires a like difference in the modes of expres-

sion. Superiors should be addressed with respect; inferiors, with courtesy; and equals, with civility. Old men and young, the grave and facetious, courtiers and philosophers, friends and strangers, require some variety in the mode of address. The epistles of Cicero, the style of which is plain and simple, and yet pleasant and engaging, furnish a proper model in this respect. They are the most valuable collection of letters in any language, as they are letters of real business, written to the greatest men of the age, composed with purity and elegance, but without the least affectation; and, what adds greatly to their merit, written without any intention of being published to the world. Pliny's letters are elegant and polite; and exhibit a very pleasing and amiable view of the author; but, according to the vulgar phrase, they smell too much of the lamp. They are too elegant and fine: and the author seems to be casting an eye towards the public, when he is appearing to write only to his friends. His style abounds so much with turns and quibbles upon the sound of words, as to render it more stiff and affected than agrees with conversation, or than a man of sense would choose to use in discourse, if it were in his power. This, indeed, was owing to the age in which he lived, at which time the Roman eloquence was sunk into puns, and an affectation of wit; for Pliny was otherwise a man of fine sense and great learning. We need not here recommend Melmoth's translation of the letters of Cicero and Pliny. The most distinguished collection of letters in the English language is that of Mr. Pope, Dean Swift, and their friends; published partly in Mr. Pope's works, and partly in those of Dean Swift. Many letters in this collection are written with ease and a beautiful simplicity. Those of Dr. Arbuthnot deserve this commendation. Dean Swift's are unaffected. Several of lord Bolingbroke's and of bishop Atterbury's letters are masterly. Mr. Pope's are too artificial. Among the French in the last age, Balzac and Voiture were the two most celebrated epistolary writers. Balzac's periods are swelling, and his style pompous; so that his reputation soon declined. Voiture continued for a long time a favourite author. His composition is extremely sparkling; he manifests much wit, and trifles agreeably. His only fault is, that he is too open and professed a wit, to be thoroughly agreeable as a letter-writer. The letters of Madam de Sevigné are now esteemed the most accomplished model of a familiar correspondence. Trifling as are their subjects, and overloaded as they are with compliments, they shew such perpetual sprightliness, they contain such easy and varied narration, and so many strokes of the most lively and beautiful painting, perfectly free from any affectation, that they are justly entitled to high praise. The letters of lady Mary Wortley Montague possess much of the French ease and vivacity, and retain more the character of agreeable epistolary style, than perhaps any letters which have appeared in the English language. Ward's Orat. vol. ii. p. 213, &c. Blair's Lect. vol. iii. Lect. 37. See **STYLE**.

**EPISTOLARY** is sometimes also applied to authors who have wrote epistles or letters. The principal epistolary authors are Sidonius Apollinaris, Tully, the younger Pliny, Seneca the philosopher, Petrarch, Politian, Busbequius, Erasmus, Lipsius, Muretus, Ascham, Milton, Petau, Launci, Sarau, Balzac, Voiture, sir W. Temple, Lyttelton, &c. &c. See the preceding Article.

**EPISTOMIA**, in *Anatomy*, are the utmost gapings and meetings of vessels.

**EPISTOMIUM**, *Επιστομιον*, from *επι*, upon, and *στομα*, mouth, in *Hydraulics*, a plug or instrument, by the application whereof

whereof the orifice of a vessel may be opened and shut again at pleasure.

EPISTROPHE, *Ἐπιστροφή*, in *Rhetoric*, a figure wherein that which is supposed of one thing is strongly affirmed of another, and the repetition of the same word occurs at the end of each member or sentence:

"Since concord was lost, friendship was lost, fidelity was lost, liberty was lost, all was lost." *Auct. ad Herenn. lib. iv. cap. 13.* See also 2 *Cor. xi. 22.*

EPISTROPHEUS, in *Anatomy*, from *ἔπι*, upon, and *στρέφω*, I turn, a name given to the second vertebra of the neck, round a particular process of which the first vertebra turns. See *SPINE*.

EPISTYLE, *Ἐπιστύλιον*, from *ἔπι*, upon, and *στυλοῦς*, column, in the *Ancient Architecture*, a term used by the Greeks for what we call architrave, viz. a massive stone, or a piece of wood, laid immediately over the capital of a column.

The epistyle is the first or lowest member of the entablature.

EPITAPH, *Ἐπιτάφιος*, from *ἔπι*, upon, and *τάφος*, sepulchre; a monumental inscription, in honour or memory of a person defunct; or an inscription engraven or cut on a tomb, to mark the time of a person's decease, his name, family, and usually some eulogy of his virtues or good qualities.

At Sparta, epitaphs were only allowed to people who died in battle. Boxhornius has made a collection of epitaphs, not very ample, but exceedingly well chosen. F. Labbe has likewise given a collection of the like kind in French, intitled, "Tresor des Epitaphes." Camden, Weaver, and Toldervy, have done something in the same way with our English epitaphs.

In epitaphs, the dead person is sometimes introduced by way of prosopopœia, speaking to the living; of which we have a fine instance, worthy the Augustan age, wherein the dead wife thus bespeaks her surviving husband,

"Immatura peri: sed tu, felicior, annos  
Vive tuos, conjux optime, vive meos."

The French have a proverb, "Menteur comme une epitaphe: He lies like an epitaph;" an allusion to the eulogies ordinarily contained therein, which are not always over-just.

EPITAPH, is also applied to certain eulogies, either in prose or in verse, composed without any intent to be engraven on tombs.

The elegance of an epitaph consists in a nervous and expressive brevity, and it is sometimes closed with an epigrammatic point. It is observed by Dr. Johnson, in his life of Pope, that the difficulty of writing an epitaph consists, in giving a particular and appropriate praise. This, he says, is not always to be performed, whatever be the diligence or ability of the writer; for the greater part of mankind have no character at all, or little that distinguishes them from others equally good or bad; and, therefore, nothing can be said of them, which may not with equal propriety be applied to a thousand more.

In the *Anthologies*, or collections of epigrams, we have abundance of epitaphs, some of them ludicrous and satirical, others grave. For a specimen, we shall here add a very beautiful one, composed by Mr. Cowley, on himself, to be put in a little country-house, whither he retreated from the court and town to spend his last days.

"Hic, O viator, sub lare parvulo,  
Conleius hic est conditus, hic jacet  
Defunctus humani laboris  
Sorte, supervacuaque vita;

Non indecora pauperie nitens,  
Et non inertis nobilis otio,  
Vanoque dilectis popello,  
Divitiis, animosus hostis.  
Possis ut illum dicere mortuum,  
En terra jam nunc quantula sufficit  
Exempta sit curis, viator,  
Terra sit illa levis, precare.  
Hinc sparge flores, sparge breves rosas;  
Nam vita gaudet mortua floribus;  
Herbilque odoratis corona  
Vatis adhuc cinerem calentem."

The following epitaphs, besides many others, are worth recording. That of Alexander:

"Sufficit huic tumulus, cui non sufficeret orbis."

That of Newton:

"Isaacum Newton  
Quem immortalem  
Testantur Tempus, Natura, Cælum,  
Mortalem hoc marmor  
Fatetur."

That of Dryden:

"Dryden."

Similar to which is that which the Italians have annexed to the tomb of Tasso:

"Les os du Tasse."

The following epitaph on the sister of sir Philip Sidney, the countess of Pembroke, and said to be written by the famous Ben Jonson, is distinguished by its admirable conclusion:

"Underneath this noble marble hearse  
Lies the subject of all verse,  
Sidney's sister, Pembroke's mother;  
Death, ere thou hast kill'd another  
Fair, and learn'd, and good as she,  
Time shall throw a dart at thee."

The following also by the same author is well known, and has been much admired:

"Underneath this stone doth lie  
As much virtue as could die;  
Which, when alive, did vigour give  
To as much beauty as could live."

Another epitaph, by Dr. Samuel Johnson, on a celebrated musician, deserves to be recorded, as it is equalled by few, and surpassed by none.

"Philips! whose touch harmonious could remove  
The pangs of guilty pow'r and hapless love,  
Rest here, distressed by poverty no more;  
Find here that calm thou gav'st so oft before;  
Sleep undisturb'd within this peaceful shrine,  
'Till angels wake thee with a note like thine."

The following epitaphs are specimens of the satirical or ludicrous kind:

Prior on himself, ridiculing the folly of those who value themselves on their pedigree.

"Nobles and heralds, by your leave,  
Here lie the bones of Matthew Prior,  
The son of Adam and of Eve;  
Let Bourbon or Nassau go higher."

On a Miser.

"Reader, beware of immod'rate love of self;  
Here lies the worst of thieves, who robb'd himself."

A similar epitaph by Dr. Swift.

"Beneath this verdant hillock lies  
Damer, the wealthy and the wise.  
His heirs, that he might safely rest,  
Have put his carcase in a chest;  
The very chest, in which, they say,  
His other self, his money, lay.  
And if his heirs continue kind  
To that dear self he left behind,  
I dare believe that four in five  
Will think his better half alive."

We shall here subjoin the epitaph of the ingenious and laborious author of the Cyclopædia, from his tomb in the cloisters of Westminster Abbey, on the north side, written by himself:

"Multis pervulgatus,  
Paucis notus;  
Qui vitam inter lucem et umbram,  
Nec eruditus, nec idiota,  
Literis deditus transegit; set ut homo  
Qui humana nihil a se alienum putat,  
Vita simul et laboribus functus,  
Hic requiescere voluit  
EPHRAIM CHAMBERS,  
R. S. S.  
Obiit 15 Maij, 1740."

In English thus:

"Heard of by many,  
Known to few;  
Who led a life between fame and obscurity;  
Neither abounding, nor deficient in learning;  
Devoted to study; but as a man  
Who thinks himself bound to all offices of humanity;  
Having finished his life and labour together,  
Here desires to rest.  
EPHRAIM CHAMBERS."

We shall close this article with some pertinent remarks on epitaphs, by an anonymous writer in the "Olla Podrida." The perusal of epitaphs is not to be considered as a light and frivolous amusement. If such only be the object of attention, as have been noticed with our applause, it is unquestionably an introduction to pleasing knowledge, and an incentive to moral improvement. What biography is to history, an epitaph is to biography. It is a sketch which marks the great outlines of character, and excites curiosity to view the portraits as painted in the pages of history. It is likewise an epitome of a sermon, which teaches the most useful truths in the most comprehensive form. Monumental inscriptions remind us, that time is on the wing, that every rank and age must fall a prey to his depredations; that the moments of life are too precious to be squandered away on trifles; that religion is the only support against the horrors of death, and the only guide to the joys of eternity.

EPITASIS, formed of *επιτενω*, *intendo*, I heighten, in the *Ancient Poetry*, denoted the second part or division of a dramatic poem, wherein the plot or action proposed and entered upon in the first part or protasis was carried on, heightened, warmed, and worked up, till it arrives at its state or height called the catastasis.

This division is laid aside in the modern drama; in lieu whereof our plays are divided into acts. See ACT.

The epitasis might ordinarily take up about our second or third act.

EPITASIS, in *Medicine*, denotes the increase or growth and heightening of a disease; or the beginning of a paroxysm, particularly in a fever.

EPITHALAMIUM, *Επιθαλαμιος*, formed of *επι*, and *θαλαμος*, *bride-chamber*, in *Poetry*, a nuptial-song, or a composition, usually in verse, on occasion of a marriage between two persons of eminence.

The topics it chiefly insists on are the praises of matrimony, and of the married couple, with the pomp and order of the marriage solemnity; it concludes with prayers to the gods for their prosperity, their happy offspring, &c. This kind of poetry is very ancient: the 44th Psalm, and the book of Canticles have been considered as specimens of the epithalamium. Stefichorus, who flourished in the forty-second Olympiad, has been usually esteemed the inventor of the epithalamium among the Greeks, though it is known that Hesiod composed the epithalamium of Thetis and Peleus, a work now lost; but a fragment of which is preserved by an ancient scholiast. Catullus exceeded all antiquity in his epithalamium, and the cavalier Marino all the moderns.

Among the Greeks, the epithalamium was sung by young men and maids at the door of the bed-chamber of the married pair in the evening and morning. The former sort were called *επιθαλαμια κομητικα*, and the latter *εγερτικα*.

EPITHEM, EPITHEMA, from *επι*, upon, and *τιθημι*, *pono*, I put, in *Pharmacy*, a kind of fomentation or remedy of a spirituous or aromatic kind, applied externally to the regions of the heart, liver, &c. to strengthen and comfort the same, or to correct some intemperature thereof.

There are principally three kinds of these external applications, the liquid, the solid, and the soft or poultice kind. See CATAPLASM and FOMENTATION.

EPITHEM, *Volatile, epithema volatile*, a form of medicine prescribed in the late London Pharmacopœia, and ordered to be made of equal weights of common turpentine and spirit of sal armoniac. The turpentine is to be kept continually stirring in a mortar, and the spirit gradually dropt in till the whole is reduced to a white mass.

The spirit of sal armoniac used in this mixture must not be that made in the common way, with the addition of quick-lime, but with the alkali salt. Pemberton's Lond. Disp. p. 377.

EPITHE'SIS, from *επι* and *τιθημι*, *to lay upon*, an old-term in *Surgery*, the meaning of which was the straightening of deformed limbs by mechanical contrivances.

EPITHET, *Επιθετος*, a noun adjective, expressing some quality of a substantive to which it is joined.

The word is formed of *επι*, upon, and *θετω*, *posito*, putting. As a fruitful vine, a stately pile, an echoing vault, &c.

Epithets are of great use and conveniency among poets and orators, who supply in epithets what they want in other requisites. Card. Perron even blames Homer on the head of epithets, observing, that he frequently hooks in epithets without any sense or significancy at all, to help out his measures; and that he equips every hero with an epithet, not according to the exigence of the case, but the measure of the verse.

EPITHEM, is also used for a surname, or a person's second appellation.

Epithets were anciently bestowed very frankly, either on account of excellencies or defects of the body or mind; kings themselves were not exempted from them. Hence these

those epithets so frequent in history, as Edward Long-shanks, Richard Cœur de Leon, Edmund Iron-side, Richard Crook-back, John Lack-land, &c.

Nor have the French used their kings any better; witness their Charles the Simple, Louis the Lazy, faintant (Ludovicus nihil faciens) Pepin the Short, Louis the Stammerer, le begue.

EPITHRICADIA, in *Antiquity*, a festival in honour of Apollo.

EPITHYME. See DODDER, and EPITHEOS.

EPITOME, an abridgment, or a reduction of the principal matters of a larger book into a little compass. See ABRIDGMENT.

The word is Greek, ἐπιτομή, formed of ἐπιτέμνω, *rescere*, to retrench, abridge, or cut off.

The epitome of Baronius's Annals is done by De Sponde (Spondanus). Bernier has given an epitome of the philosophy of Gassendus.

It is a popular objection against the epitomizing of authors, that it frequently occasions the loss of the originals. Thus the loss of the historian Trogus Pompeius is attributed to his epitomizer Justin, and the loss of a great part of Livy to Luc. Florus. See LIVY.

"Epitomes," says the learned Bacon, "are the moths and corruptions of history, that have fretted and corroded the sound bodies of many excellent histories, and wrought them into base and unprofitable dregs."

EPITRITES, from ἐπι, and τρις; *third*, in *Prosody*, a foot consisting of four syllables, three long, and one short.

Grammarians reckon four species of epitrites; the first, consisting of an iambus and spondee, as *salūtāntēs*; the second, of a trochee and spondee, as *cōncitātī*; the third, of a spondee and an iambus, as *cōmmūnicāns*; and the fourth, of a spondee and trochee, as *incāntārē*.

EPITRITES, among the *Greek Musicians*, denoted a ratio, called also the sesquiquartal ratio, the same with that of three to four. See FOURTH.

EPITROCHASMUS, in *Rhetoric*, a figure wherein we slightly pass over several things of great moment, by only mentioning them in general. Such is the saying of Cæsar, *Veni, vidi, vici*.

EPITROPE. See CONCESSION. This is one of the figures of sentences, which grants one thing to obtain another more advantageous. It is either real or feigned; and either the whole of a thing, or only a part is granted. Nothing more confounds an adversary, than to grant him his whole argument, and at the same time either to shew that it is nothing to the purpose, or to offer something else, which may invalidate it. Of the use of this figure we have examples in Cicero's defence of Ligarius, who was accused by Tubero for having joined with Pompey in the civil war between him and Cæsar, (cap. 1.); and in the affair of Roscius, where the proof depended upon circumstances; and when Cicero, who defended him, inquires what reason could be alledged for his committing so black a crime, as to kill his father, (cap. 27.) Cicero has also given us an example of a feigned or ironical concession in his defence of Flaccus (cap. 38.); when interceding for him on account of his former good services, in the time of Catiline's conspiracy, he says in the way of irony, if such things are to be overlooked, "let us appease the ghosts of Lentulus and Cethegus; let us recall those who are in exile, and let us be punished for our too great affection and love for our country." To these feigned concessions we may refer such modes of reasoning, by which the orator both justifies a charge brought against him, upon the supposition of its being true; and also proves that the charge itself is

false. Thus Cicero, in his defence of Milo, represents the taking off of Clodius, with which Milo was accused, as a glorious action; after he has shewn that Milo's servants did it without the knowledge of their master. (Cap. 10. and 27.)

EPITROPUS, a kind of judge, or rather an arbitrator, which the Greek Christians under the dominion of the Turks elect in the several cities, to terminate the differences that arise among them, and avoid carrying them before the Turkish magistrates. See ARBITRATOR.

There are several epitropi in each city. M. Spon, in his Travels, observes, that at Athens there are eight taken out of the several parishes, and called *vecchiardi*, *i. e.* old men. But Athens is not the only place where there are epitropi; they are in all the islands of the Archipelago.

Some Latin authors of the sixth century call epitropi those who more anciently were called *villici*, and since *vidames*.

In times still earlier, the Greeks used the term ἐπίτροπος, in the same sense as the Latins did *procurator*, *viz.* for a commissioner or intendant.

Thus the commissioners of provisions in the Persian army are called by Herodotus and Xenophon epitropi. In the New Testament, ἐπίτροπος denotes the steward of a household, rendered in the vulgate procurator.

EPIZEUXIS, in *Rhetoric*, a figure where the same word is repeated with vehemence in the same sense, without any others intervening, and suited to express anger, surprise, sorrow, and several other passions: thus *age, age; adeste, adeste*; and that of Virgil, *nunc, nunc, insurgite remis*, are instances of it. Thus also, when Cicero would express his indignation against Antony for having been the chief instrument in bringing on the civil war, he says to him: "You, you, Antony, pushed Cæsar upon the civil war." (Philip. ii. c. 22.) Thus he tells Catiline in his first invective against him; "You live, and live, not to lay aside, but to pursue your wicked design." (Ibid. cap. 2.) See Matthew xxiii. 37. The use of this figure shews the earnestness of the speaker and the great concern of his mind about what he says, and has a natural tendency to excite the attention of the audience.

EPIZOOTIC STRATA, or *Mountains*, in *Geology*, are such as contain remains of animals, which a very large portion of all those upon the surface of the earth seem to do, although their reliquæ are by no means equally numerous in all strata, probably owing to their not being preserved in every instance, so that their remains or impressions can be now traced.

EPIZOOTY, a denomination given to an epidemical or contagious distemper among horned cattle. M. de Saive, apothecary to the prince bishop of Liege, has given the following instructions for the prevention and cure of this disorder. As soon as any symptoms of the distemper are perceived, about 1½ pint of blood should be taken from the beast, unless he has been ill a day or two, in which case he should not be bled; but in both cases the following draught should be given, *viz.* N<sup>o</sup> 1. an ounce of the best Venice treacle dissolved in a pint of vinegar, after which the back-bone and the whole hide must be well rubbed with a dry hair cloth, to heat the hide and promote perspiration. No drink should be given him; but a white drink composed of (N<sup>o</sup> 2.) a handful or two of rye-meal in a pailful of clean water; and if the beast should want food, mix up some crumbs of rye bread with some of this white drink, and give it him. The animal's mouth must be washed twice a day with a cloth dipped in a mixture of (N<sup>o</sup> 3.) equal quantity of vinegar and water, with a spoon-

ful of honey to a pint of it. If on the second day the beast has not dunged, a clyster composed of (N<sup>o</sup>. 4.) a pint of water in which bran has been boiled, two spoonfuls of salt, and a small glass of vinegar must be given and repeated every day till the evacuations are natural and regular. Besides the above remedies, the following cordial mixture (N<sup>o</sup>. 5.) viz. a pint of clear water, the same quantity of vinegar, four spoonfuls of honey or syrup, and two glasses of brandy, must be given four times a day to facilitate and keep up perspiration; taking particular care to repeat the friction as above directed. If the beast should still continue low and heavy, the draught (N<sup>o</sup>. 1.) must be repeated, unless he should be found to be hot and thirsty, in which case only the drink (N<sup>o</sup>. 2.) should be used. On the fourth day, if he seems more lively and free from heat, purge him with (N<sup>o</sup>. 6.); two ounces of salts and one ounce of common salt, dissolved in a pint of lukewarm water, with two spoonfuls of honey. If this does not procure four or five evacuations, repeat the clyster the same day.

This mode of treatment must be continued without intermission till the beast begins to eat; then he must have only the white drink (N<sup>o</sup>. 2) and a little good fodder, or some rye-bread dipped in stale-beer, moderately sweetened with honey or syrup. The exterior treatment consists in the application of setons in the beginning of the distemper, at the bottom of the dewlap, and of cauteries towards the horns, between which some weight, *e. g.* a stone of a pound weight or more, wrapped up in a cloth, must be fixed in order to keep it steady. This is necessary to keep the head warm. But above all, the friction must be carefully attended to, for determining the critical efforts of nature. It would be proper also to evaporate vinegar in the cow-house, &c. and if it could be done without risk, blowing of a few grains of gunpowder in them twice a day would be a very useful fumigation. If, notwithstanding these aids, the beast be not perfectly cured in ten or twelve days, they must be continued without bleeding, unless the inflammation be very considerable; but if, after all, the distemper does not give way, the beast must be killed, buried very deep, and well covered with earth and turf, for the purpose of preventing the exhalation of the putrid vapours and the spread of the infection. The principal preservatives from infection consist in washing the racks, troughs, &c. and the hide of the beast every day, with plenty of water; and instead of expensive aromatic fumigations sometimes recommended, the use of fires made with the branches of green wood, with pitch thrown on it to quicken the flames and perfume the air. Common salt given in small quantities every day to horned cattle, is reckoned an excellent preservative, particularly in a learned dissertation on the contagious distempers among horned cattle, by M. de Limborg, M.D. F.R.S. Letters, &c. on Agriculture of the Bath, &c. Society, vol. i.

EPLOYE', in *Heraldry*. An eagle employé is what in English we more usually call an eagle displayed, or a spread eagle. See DISPLAYED.

EPNEUMATOSIS, from *πνευματος*, *I breathe*, in *Medicine*, the same with expiration.

EPOBOLIA, in *Antiquity*, a fine laid upon those that could not prove the indictment they had brought against their adversaries.

It was so called, because they were obliged to pay the sixth part of the value of the thing they contended for, viz. an obolus out of every drachm. Some of these sums were deposited in all law-suits, a very few excepted, before the trial could proceed. Potter. *Archæol. Græc. lib. i. cap. 21. tom. i. p. 117.*

EPOCH, in *Astronomy*, is the mean longitude of a planet for the commencement of a given year. It is one of the principal elements of the elliptic motion. (See ELEMENT and ELLIPTIC Motion.) When two observations of a planet are made in the mean distances, that is, at three and nine signs of mean anomaly, it is then practicable to correct, by two such observations, both the epoch and equation of the centre. If the latter is exact, there will be no other difference between the calculation and observation than the epoch of the mean motion, since the place of the aphelion does not influence the longitudes taken at the mean distances; the error will, therefore, be equal in the two observations, for we suppose the mean motion known exactly. Thus, if the errors of the tables are found equal at three and nine signs of anomaly, it is a proof that the equation of the centre is exact, and that the error lies wholly in the epoch being improperly assumed.

EPOCHÆA, in *Chronology*, a term or fixed point of time, whence the succeeding years are numbered or accounted.

The word is *εποχη*, *q. d. inhibitiō, repressiō*, formed of *επιχειν*, *to sustain, stop*, because the epocha defines or limits a certain space of time. For the difference between epocha and era; see ÆRA.

Different epochas obtain in different nations; and no wonder; for there being no astronomical consideration to render one preferable to another, their constitution is purely arbitrary. That principally regarded among Christians is, the epocha of the Nativity or Incarnation of Jesus Christ; that of the Mahometans, the Hegira; that of the Jews, &c. the Creation of the World; that of the ancient Greeks, the Olympiads: that of the Romans, the Building of the City; that of the ancient Persians and Assyrians, the epocha of Nabonassar, &c.

The doctrine and use of epochas are of very great extent in chronology.

To reduce the years of one epocha to those of another, *i. e.* to find what year of one corresponds to a given year of another; a period of years has been invented, which, commencing before all the known epochas, is, as it were, a common receptacle of them all, called the Julian period. To this period all the epochas are reduced, *i. e.* the year of this period whereon each epocha commences is determined. All that remains, therefore, is, to add the given year of one epocha to the year of the period corresponding with its rise; and from the same to subtract the year of the same period corresponding to the other epocha; the remainder is the year of that other epocha.

EPOCHÆA of *Christ*, or of our Lord, is the vulgar epocha throughout Europe, commencing from the supposed time of our Saviour's nativity, December 25, or rather according to the usual account, from his circumcision, that is, from the first of January.

Now, the year of the Julian period, wherein Christ was born and circumcised, is usually computed to be the 4713th; consequently, the first year of the era of Christ corresponds to the year 4714 of the Julian period.

Hence, 1. If to any given year of Christ you add 4713; the sum will be the year of the Julian period corresponding thereto, *E. gr.* If to the year 1809 be added 4713, the sum 6522 is that year of the Julian period.

2. On the contrary, subtracting 4713 from any given year of the Julian period, the remainder is the current year of Christ. *E. gr.* from the year of the Julian period 6522; subtracting 4713, the remainder is the year of Christ 1809.

In effect, the epocha of our Lord serves not only for the computation

## E P O C H A.

computation of the years elapsed since the epocha commenced, but even of those before it.

Now, to find the year of the Julian period corresponding to a given year before Christ, subtract the given year from 4713, the remainder is the correspondent year required. Thus, *e. gr.* the year before Christ 752, is the year 3961 of the Julian period. On the contrary, subtracting the year of the Julian period from 4713, the remainder is the year before Christ.

The author of the vulgar epocha, or way of computing from Christ, is an abbot of Rome, one DIONYSIUS *Exiguus*, (which see,) by nation a Scythian, who flourished under Justinian about the year 507, or, according to others, 527, though this Dionysius borrowed the hint from Panodorus, an Egyptian monk. Till his time, the generality of Christians computed their years either from the building of Rome, or according to the order of the emperors and consuls, and by other ways in use with the people among whom they lived.

This diversity occasioning a great distraction between the churches of the East and West; Dionysius, to compose the same, first proposed a new form of the year, with a new general era, which in a few years time was generally admitted.

Dionysius began his account from the conception or incarnation, by us popularly called Lady-day, or the Annunciation; which method obtained in the dominions of Great Britain till the year 1752, before which time the Dionysian and English epocha was the same; but in that year the Gregorian calendar having been admitted by act of parliament, they now reckon from the first of January, as they do in the other countries of Europe, except in the court of Rome, where the epocha of the incarnation still obtains for the date of their bulls.

It must be added, that this epocha of Dionysius is charged with a mistake: the common opinion is, that it places our Saviour's nativity a year too late; or that he was born the winter preceding the time prescribed by Dionysius for his conception.

But the truth is, the fault lies on Bede, who misinterpreted Dionysius, and whose interpretation we follow, as has been shewn by Petavius from Dionysius's own epistles; for Dionysius began his cycle from the year 4712, but his epocha from the year 4713, wherein the vulgar era supposes Christ to have been incarnate.

The year, therefore, which, according to the vulgar epocha, is the first year of Christ, according to Dionysius's era is the second; so that the year which we call 1809, should, in justice, be 1810, though some chronologers, instead of one year, will have the error two.

Others suppose that the Dionysian era is four years too late; which supposition is confirmed by considering that our Saviour was born before the death of Herod the Great; and during the reign of Augustus (Matth. ii. 1. 22. Luke, ii. 1.) and according to the testimony of Josephus, (lib. xvii. cap. 18.) there was an eclipse of the moon in the time of Herod's last illness; which eclipse appears to have happened in the year of the Julian period 4710, March 13, at Jerusalem. Now, as our Saviour must have been born some months before Herod's death, since in the interval he was carried into Egypt, the latest time in which we can fix the true era of his birth is about the end of the 4709th year of the Julian period.

In order to ascertain the true year of our Saviour's birth, it is necessary to fix the precise time of Herod's death. The chief opinions concerning the time of this event are three. Some think he died a little before the passover of

A. U. 750, Julian year 42; others on Nov. 25 in that year: and others, a short time before the passover A. U. 751. We learn from Josephus, (De Bell. lib. ii. c. 1. Antiq. l. xvii. c. 9.) whose authority we cannot reject in deciding this question, that Herod died but a short time before one of the Jewish passovers. That Herod died a short time before the passover A. U. 750, Julian year 42, is argued in this manner. His distemper had made great progress before the pulling down of the golden eagle at the temple. The Jewish rabbies excited their scholars to this action. News being brought that Herod was *dying* (Jof. de Bell. l. i. c. 33. § 1.) or *dead* (Jof. Ant. l. xvii. c. 6. § 3.) these rabbies were taken up and carried to Jericho, where Herod was, in a very infirm state, and where they were tried and burnt to death. On that very night there was an eclipse of the moon, which, as we have already mentioned, happened March 13th A. U. 750. From this time Herod grew worse and worse; so that he could not live long. The passover of this year happened on the 11th of April; and the interval between the 13th of March and 11th of April would have been sufficient for every thing that Josephus has related concerning Herod's illness; the settling of his affairs, the execution of Antipater, Herod's death and funeral, which are the occurrences between the eclipse and Archelaus's coming to Jerusalem at the passover.

Besides, from circumstances related by Josephus concerning Archelaus, one would be apt to conclude, that he reigned nine years complete, and that the 10th year was current when he was banished. Dio (l. lv. p. 567.) places Archelaus's banishment in the 759th year of Rome. If Herod did not die, as some imagine, till the beginning of A. U. 751, the 9th year of Archelaus's reign could not be completed in the 759th year of Rome. But if Herod be supposed to have died in the beginning of A. U. 760, Josephus and Dio agree. Moreover, Josephus says, that Cyrenius seized Archelaus's estate, and finished the assentment in Judea in the 37th year after the defeat of Antony at Actium by Cæsar Augustus. The victory at Actium was obtained Sept. 2, A. U. 723; therefore the 37th year from it begins Sept. 2, A. U. 759, and ends Sept. 2, 760. Supposing then that Herod died in the beginning of A. U. 750, there is in this particular also a very good harmony between Josephus and Dio. Besides, Josephus informs us (Ant. l. xiv. c. 29.) that Herod was appointed king by the Roman senate A. U. 714. *i. e.* 40 years before the vulgar era. The same historian observes, that he died in the 37th year of this reign, and 34th after the death of Antigonus, *viz.* in the 42d Julian year (Antiq. l. xvii. 10.) If to 713 we add 37, the sum will be 750, the year of Rome in which this prince died.

The opinion, adopted by other learned men, that Herod died a short time before the passover A. U. 751, labours under several great difficulties, which are pointed out by Dr. Lardner (*ubi infra*). Upon the whole it appears, that Herod did not die before the year 750, nor survive the year 751, and that he died a short time before the Jewish passover of one of these years. It follows, that if Herod died in 750, he died three years and nine months before the vulgar Christian era, which commences January 1, A. U. 754; if at the time above-mentioned, in the year 751, then he died about two years and nine months before the said era. "Which is the truth," says Dr. Lardner, with his usual diffidence and modesty, "I am not able to determine." Accordingly he says, that "if Herod died in March A. U. 750, I should be inclined to place the nativity of Jesus in September or October, A. U. 748; if Herod died in March 751, then the nativity of Jesus might  
very

very well be placed in September or October 749." The birth of Jesus must be dated about a year and five or six months before the death of Herod, *i. e.* before the latter end of the year of Rome 748 or 749, *i. e.* 4708 or 4709 of the Julian period; but for reasons already assigned, the latter date is the most probable.

We shall here add, that an objection has been urged against the 15th year of the reign of Tiberius, compared with the age of Jesus at his baptism. (Luke, iii. 1, 2. 23.) If Jesus, it is said, was born above a year, much more, if above two years before Herod's death, then the age of 30 years, here ascribed to him at his baptism, is absolutely inconsistent with the notes of time mentioned at the commencement of John the Baptist's ministry; even allowing, that *the word of God came to John* in the very beginning of the 15th year of Tiberius, and that Jesus was baptized a few months after. Dr. Lardner observes, that the true meaning of these words, *Jesus himself began to be about 30 years of age*, is not that he then entered the 30th year of his age, but that Jesus was about 30 years of age when he began his ministry. This, he says, is now the general opinion of learned men; so the Greek word of this text is used by St. Luke in other places. The objection is thus stated: Augustus died, and Tiberius succeeded him the 19th of August, A. U. 767, Julian year 59, A. D. 14. Therefore the 15th of Tiberius began the 19th Aug. A. U. 781, A. D. 28. Herod died before the passover, in A. U. 751, Jul. year 43. If then John the Baptist began to preach in the beginning of the 15th of Tiberius, in the latter end of A. U. 781, and Jesus be supposed to have been baptized by John a few months after, on the 6th of January of the year following, *viz.* A. U. 782, Jesus must have been in the 32d year of his life, if Herod died in the spring, *viz.* A. U. 751, and if Jesus was born the 25th of December preceding, *viz.* A. U. 750. But if Herod died A. U. 750, and Jesus was born the 25th December before, *viz.* A. U. 749, then he would be at his baptism in the 33d year of his age. But it may be made to appear in several ways, that Jesus was born above a year, probably above two years before Herod died. Dr. Lardner has stated this objection in its full force; and detailed several circumstances that tend to obviate it. From some of them he infers, that there is no necessity of placing the birth of Jesus above a year and six months before the death of Herod, as we have already stated. As it is most probable that Herod died A. U. 750, we may be disposed, from other circumstances alleged by this accurate and impartial writer, to place the nativity of Jesus in September or October A. U. 748. The latter part of the summer, or the autumn season, seems to be the most likely time of the year for the birth of Jesus; nor is there any particular reason that should determine us to the 25th of December. The very depth of winter was not a very proper season for a survey and assessment, when people are to enter themselves according to their tribes or families; the autumn, when harvest and vintage are over, would be a time of general leisure. When Jesus was born in Bethlehem, *there were in the same country shepherds abiding in the field, keeping watch over their flocks by night*, (Luke, ii. 8.) This circumstance is not very favourable to the supposition, that Jesus was born the 25th of December; and we are at liberty to place it in autumn, a more likely season. (See CHRISTMAS.) It is not improbable then, that Jesus might be born some time between the middle of August and the middle of November. Cyrenius, we may suppose, came into Judea at the time, or soon after the time, that Varus became governor of Syria (before Sept. A. U. 748), and published the decree of Augustus, requiring all peo-

ple to enter themselves, their dependents, and estates. This assessment could well be made in a country of such small extent as Judea in two or three months; and the short time appointed for this work may be inferred from the peculiar circumstances of Cyrenius, who wished to hasten back to Rome, and also from St. Luke's history of it. Upon the whole, we may conclude, that about a year and six or seven months before the death of Herod, soon after the arrival of Varus in the province of Syria, in August or September A. U. 748 or 749, Julian year 40 or 41, Cyrenius (or some other person of eminence) came into Judea, an assessment was made there, and in the time of it, Jesus was born at Bethlehem, in the month of September or October. In order, however, to settle satisfactorily the 15th year of the reign of Tiberius, we should consider that the commencement of his reign may be computed from a different period than that of his sole empire, after the death of Augustus. In fact, it appears, that there were two different dates of the beginning of Tiberius's reign; one from the time of his being made colleague with Augustus, and the other from his sole empire, after the death of Augustus. Many learned writers are of opinion, that St. Luke intends the former of these two computations, referring to a period two years before the death of Augustus, *viz.* in A. U. 765, when Piso was præfect of Rome, Tiberius being prince. Archbishop Usher and Prideaux place the beginning of this government of Tiberius in this year. This epoch of Tiberius's empire was followed for some time by some persons, in the provinces at least; but it is not so certain, when this pro-consular empire began, whether about two years, or about three years before Augustus died. If Tiberius's proconsular empire began about three years before Augustus died, on the 28th of August A. U. 764, A. D. 11, then this 15th of Tiberius's reign (according to this computation of it) began August 28th, A. U. 778, A. D. 25. Supposing that John the Baptist began his ministry November following, in the same year, and that Jesus was baptized by him the 6th of Jan. following, in A. U. 779, A. D. 26; then upon the supposition that Jesus was born in Sept. A. U. 748, he would be at his baptism 30 years of age, and some months more. If Tiberius's proconsular empire commenced about two years before the death of Augustus, in A. U. 765, A. D. 12, then the 15th year of the reign of Tiberius began in A. U. 779, A. D. 26. And supposing that John the Baptist began his ministry in November of that year, and that Jesus was baptized by him the 6th of January following, A. U. 780, A. D. 27, then, upon the supposition that Jesus was born in September, A. U. 749, he would be at the time of his baptism 30 years of age, and some months more; or, if born A. U. 748, he would be somewhat more than 31 years of age. Again, if John the Baptist began his ministry in the 15th of Tiberius, A. U. 778, A. D. 25, according to the first statement, but did not baptize Jesus till the 6th of January, A. U. 780, A. D. 27, after he had preached somewhat above a year, then Jesus would be at his baptism 30 years of age and odd months, if he was born A. U. 749; 31 years of age and some odd months, if born the latter end of the year 748. Such will be the result, if we take those dates of these events, which appear most favourable to St. Luke; since it is not absolutely certain when Herod died, or when Tiberius's proconsular empire began. But if we allow on each hand the dates least favourable to St. Luke's numbers, *viz.* that Jesus was born A. U. 748, and that he was not baptized till January A. U. 780, A. D. 27; yet even then Jesus would be little more than 31 years of age; at which time a person

person may be said very properly to be ABOUT *thirty years of age*.

The question of our Lord's nativity and age at his baptism is amply discussed, and the difficulties which it involves accurately and impartially examined, by Dr. Lardner in his "Credibility, &c." See his Works, vol. i. See also Playfair's System of Chronology, p. 49, &c.

Learned men have differed in opinion concerning the precise time of the death of Christ. Some have referred this event to the 29th year of the vulgar era; others to the 31st; and not a few to the 33d. Playfair (with whom Blair agrees) inclines to adopt the last of these dates, for the following reasons. 1. There is no other year besides the 33d of the vulgar era, 78th Julian year, 4746th of the Julian period, A. U. 786, to which this event can be properly referred; for Jesus Christ went to eat the passover with his disciples on the evening of the 14th of the first month, and was crucified on the day following, *viz.* on Friday, April 3d, the 16th day of the paschal moon, according to the true, and the 15th, according to the Jewish computation. 2. The 70 weeks of Daniel, which began in the 20th year of Artaxerxes Longimanus, and ended in J. P. 4746, when Messiah was cut off. 3. Phlegon, the freedman of Adrian, and esteemed as an exact computer of the Olympiads, observed "that in the 4th year of the 202d Olympiad, there was a miraculous darkness; for at the sixth hour of the day came on night, insomuch that the stars of heaven were seen. At the same time, there was also a great earthquake in Bithynia, which threw down part of the city of Nice." (Compare this account with Matth. xxvii. 45. and Luke, xxiii. 45.) The 4th year of the 202d Olympiad answers to the first six months of the 33d year of our vulgar era, and to the 19th of the reign of Tiberius. Concerning the testimony of Phlegon; see PHLEGON. 4. When Christ suffered, Pontius Pilate was governor of Palestine (Tacit. l. xv. Joseph. Antiq. l. xviii. c. 5.); Herod Antipas was tetrarch of Galilee (Luke, xxiii. 6. Joseph. Antiq. l. xix. c. 7.); and Caiaphas was high-priest among the Jews (John, xi. 49. Luke, iii. 2. and Acts, iv. 6.) (See CAIAPHAS.) From these and other characters it appears, says Playfair, that Jesus Christ lived about 36 years, 3 months, 9 days, and 15 hours, if we reckon (according to the generally received opinion concerning the month and day of his nativity) from midnight of December 25th, of the 42d Julian year commencing, to April 3d and 3 in the afternoon, of the 78th Julian year. His resurrection took place on Sunday April 5th, and his ascension on Thursday May 14th.

To the vulgar era of our Lord's nativity, as a sure fixed point, chronologers have been accustomed to reduce all the other epochs, though there is not one of them but what is controverted; so much uncertainty there is in the doctrine of time. We shall exhibit them as reduced to the Julian period.

ΕΠΟΧΑ of the Creation, *Orbis Conditi*, according to the computation of the Jews, called also the Jewish epocha, is the year of the Julian period 953, answering to the year before Christ 3761, and commencing on the seventh day of October. Hence subtracting 952 years from any given year of the Julian period, the remainder is the year of the Jewish epocha corresponding to it. Thus, *e. gr.* the year 1809 being the 6522d year of the Julian period, it is the 5570th year of the Jewish epocha, or since the creation of the world.

This epocha is still in use among the Jews.

The ΕΠΟΧΑ of the Creation, used by the Greek historians, is the year before the Julian period, 787, answering to the year before Christ 5500.

VOL. XIII.

Hence, to any given year of the Julian period, adding 787, the sum gives the year of this epocha. *E. gr.* 1809 being the 6522d year of the Julian period, 7309 is that year of this epocha, or the year of the world, according to this computation.

The author of this epocha is Julius Africanus, who collected it from the historians: but when it came to be admitted into civil use, 8 years were added to it, that so every year thereof divided by 15 might exhibit the indication, which the eastern emperors used in their charters and diplomas.

The epocha of the creation used by the latter Greeks and Russians is the year 795 before the Julian period, or the year 5508 before Christ, commencing from the first day of September. Though the Russians, having lately admitted the Julian calendar, begin their year from the first of January.

Hence, adding 795 to the year of the Julian period, the sum gives the year of this epocha. Thus, *e. gr.* the Julian period of the year 1809 being 6522, that year of this epocha, *i. e.* the years from the creation on this footing are 7317. Again, from that year 7317 subtracting 5508, the remainder is the year of the common era 1809. This era was used by the emperors of the East in their diplomata, &c. and thence also called the "civil era of the Greeks." In reality, it is the same with the epocha of the Constantinopolitan period; whence some call it the "epocha of the period of Constantinople."

The Alexandrian ΕΠΟΧΑ of the Creation is the year 780 before the Julian period, answering to the year before Christ 5493, and commencing on the 29th day of August.

Hence, adding 5493 to the year of Christ 1809, the sum 7302 gives that year of this epocha, or years elapsed since the creation, according to this computation.

This epocha was first concerted by Panodorus, a monk of Egypt, to facilitate the computation of Easter; whence some call it the "Greek ecclesiastical epocha."

The Eusebian ΕΠΟΧΑ of the Creation, is the year of the Julian period 486, answering to the year before Christ 4228, and commencing in autumn.

Hence, subtracting 486 from the year 6522 of the Julian period, or adding 4228 to the year of Christ 1809, the result 6036 will be that year of this epocha.

This epocha is used in Eusebius's Chronicon, and the Roman Martyrology.

The ΕΠΟΧΑ of the Creation, according to Mr. Bedford and Mr. Kennedy, is the year of the Julian period 706, answering to the year before Christ 4007.

The ΕΠΟΧΑ of the Creation, according to archbishop Usher, adopted in Blair's tables, is the year of the Julian period 710, corresponding to the year before Christ 4004; but it must be allowed, that all the epochs of the creation are uncertain. See Strauchius's Brev. Chron. by Sault. p. 152, &c. See chronological table under the article CHRONOLOGY.

ΕΠΟΧΑ of the Universal Deluge, in the year of the creation 1656, and according to the different methods of computation; see the table under CHRONOLOGY, and ANTE-DILUVIAN.

ΕΠΟΧΑ of the Olympiads, is the year of the Julian period 3938, answering to the year 776 before Christ, commencing at the full moon next the summer solstice, and each Olympiad containing four years.

This epocha is very famous in ancient history; it was used principally by the Greeks, and had its origin from the Olympic games, which were celebrated at the beginning of

every fifth year. See the table above cited, and OLYMPIC Games.

EPOCHÆ of the Building of Rome, or *Urbis Condita*, U. C. is the year of the Julian period 3961, according to Varro; or 3962, according to the *Facti Capitolini*, answering to the year before Christ 753 or 752, and beginning on the 20th of April. Hence, if the years of this epocha be fewer than 754, subtracting them from 754 or 753, you have the year before Christ; and, on the contrary, if they be more than 754, you must subtract 754 to have the year of Christ, and add the year of Christ to 754 to have the year of this epocha, or the time since the building of Rome. Thus, *e. gr.* the year 1809, according to Varro, is the year of Rome 2563.

The sentiments of the earliest Roman writers, with respect to this epoch, are various; Polybius refers it to the year B. C. 751. Cato, whose opinion is adopted by Solinus, Eusebius, Dionysius Halic. &c. places it one year earlier. Fabius Pictor, who flourished in the time of the first Punic war, and who is styled by Dion. Hal. an accurate writer, brings it down to the 29th year of the olympiads, *i. e.* 747 B. C. Diodorus Siculus adopts this opinion. Sir Isaac Newton, on the testimony of some later Roman writers, observes that Rome was built in the 15th age after the destruction of Troy, that is, after the 14 kings who reigned in Alba. Allowing 21 years to the reign of every king, and computing from the year B. C. 904, when he supposes Troy to have been taken, he brings forward this epoch to the 38th olympiad, *i. e.* 627 B. C. The date of Varro has been adopted by the Roman emperors in their proclamations, by Plutarch, Tacitus, Dion, Gellius, Censorinus, Onuphrius, Baronius, and by most modern chronologers.

EPOCHÆ of *Nabonassar*, is the year of the Julian period 3967, answering to the year before Christ 747, commencing the 26th day of February of the Julian year at mid-day. The solar cycle was 19, the lunar 15, and the cycle of indiction 7.

This era takes its denomination from its institutor Nabonassar king of Babylon, and is that used by Hipparchus, by Ptolemy in his *Astronomical Observations*, by Censorinus, and others.

This epoch is of singular service in chronology, as it serves to connect and adjust all other epochas. The form of this era, which included a period of 424 Egyptian years from the commencement of Nabonassar's reign to the death of Alexander the Great, and which was thence carried down to the reign of Antoninus Pius, is singular. Every year consists of 365 days, and is divided into 12 months. Every month contains 30 days; five intercalary days are added to these months, and the sum composes the quantity of the Nabonassarean year. In every four Julian years, the corresponding four years of this era were evidently deficient by one day; therefore the beginning of the Nabonassarean years must have moved retrogradely; and in the space of 1460 Julian years, must have gone through every day of the year. Whence it appears, that 1460 Julian are equal to 1461 Nabonassarean years. If the first year of the era of Nabonassar began on Wednesday, Feb. 26th, the second and third years must have begun on the same day; because these two years contain 365 days each in the Julian, as well as in the Egyptian calendars. The following year, *i. e.* 744 B. C. being a bissextile, one day was added to the Julian year, consequently the Nabonassarean year began on Feb. 25th in this and the three succeeding years. In the year 740 B. C. it began on February the 24th; in 736 B. C. on February

the 23d, &c. The first day of any year of the Nabonassarean era may be found by the following general rule.

Divide the given year by 4 (because in 4 years the Nabonassarean year anticipates the Julian by one day), and the quotient will be the number of days of anticipation, or of the omitted leap-days. If the quotient be less than 57 (the number of days from January 1st to February 26th), let it be subtracted. If the quotient exceeds 57, subtract it from 422, *i. e.* from 57 + the number of days in one Julian year, and the remainder will be the day of the Julian year, reckoned from January 1st, which is the *Thoth*, or first day of the year following the given one; (*Thoth* being the name of the month, which in the first year of this era corresponded to Feb. 26th of the Julian year.) From the day found, subtract 1, and the remainder will be the number of the day required.

E. G. On what day of the Julian year did the *Thoth* of the Nab. era 230 fall? Divide 230 by 4, and the quotient 57, subtracted from 422, leaves a remainder of 365. This shews that the *Thoth* of N. E. 231st falls on December 31st, or on the 365th day of the Julian year: subtract 1, and the remainder 364, or December 30th, will be the day required.

EPOCHÆ, or *Era of Constantinople*, is supposed to have commenced before the creation of the world; for the 5509th year of it answers to the 1st of the vulgar Christian era. It was adopted by the Greek church and empire, all the public acts of which are still dated by it; and the Muscovites computed by it until the reign of Peter the Great. Those who reckon by it make use of civil and ecclesiastical years. The former begin with the month of September, and the latter, sometimes with the 21st of March, and sometimes with the 1st of April.

EPOCHÆ of *New Rome*, or *Constantinople*, is usually computed from the time of the consecration of the city. Accordingly the first year of this era was the 25th of the reign of Constantine, A. M. 5838, as the modern Greeks estimate the era of the creation, Julian period 5043. Thus directed, the consecration of the city is fixed in the 330th year of the vulgar era, on the 11th of May.

EPOCHÆ, *Dioclesian*, or *Epocha of Martyrs*, is the year of the Julian period 4997, answering to the year of Christ 284, called the "era of martyrs," from the great number of Christians who suffered martyrdom under the reign of that emperor.

The Abyssinians, among whom it is still used in all ecclesiastical computations, call it the "year of grace;" though they do not reckon their years in a continued series, from this epocha. But when the Dionysian period of 534 years is expired, they begin their computation afresh from 1, 2, &c.

EPOCHÆ of the *Hezira*, or *Mahometan Epocha*, is the year of the Julian period 5335, answering to the year of Christ 622. It commences on Friday the 16th of July, the day of Mahomet's flight from Mecca to Medina.

This epocha is used by the Turks and Arabs, and even all who profess the Mahometan faith. It was first introduced by Omar, the third emperor of the Turks. The astronomers Alfraganus, Albategnius, Alphonfus, and Ulugh Beigh, refer Mahomet's flight to the 15th of July; but all the people who use the epocha agree to fix it on the 16th. See HEGIRA.

EPOCHÆ of the *Seleucida*, which is used by the Macedonians, is the year of the Julian period 4402, answering to the year before Christ 312. This is reckoned from the time when Seleucus, one of the generals of Alexander's army, took Babylon and ascended the Asiatic throne.

This era is sometimes called the Grecian era, and the era of Principalities, in reference to the division of Alexander's empire. The Arabians style it "Tarik Dhilcarvaim," *i. e.* the era of Contracts, and the Greeks denominate it the Horned era. Those who use it reckon sometimes by Nabonassarean years, and sometimes by Julian, composed of Roman months, to which Syrian names have been affixed. Its commencement has been variously stated, some date it on Tuesday March 13th. The Greeks in Syria reckon from a month corresponding to our September. Albategni, and others, reckon from the 1st of October. In the first book of Maccabees the year is said to have began in Nisan, or the first month of spring; but in the second book, and in other Jewish histories, its beginning is dated in Tizzi, which is the first month of autumn. See SELEUCIDÆ.

EPOCHÀ, *Persian*, or *Yezdegerdic*, is the year of the Julian period 5345, answering to the year of Christ 632, and commencing on the 16th of June.

This epocha is taken from the death of Yezdegerdis, the last king of Persia, slain in battle by the Saracens. See *Persian CALENDAR*.

EPOCHÀ, or *Era of the Persian Monarchy*, is referred by almost all ancient historians to the 1st year of the 55th olympiad, *i. e.* 560 B. C. Of this opinion are Diodorus Siculus, Thallus, Censor, Polybius, Phlegon, and Eusebius. From the beginning of the Nabonassarean era to the first year of the reign of Cyrus over Babylon, Ptolemy reckons 209 years. If this number be subtracted from 747, the remainder 538 will be the Babylonian epoch of Cyrus; and the monarchy stood, according to Agathias, from the first year of Cyrus 228 years. That this was its duration is evident from a passage of Plutarch (in Vit. Alex.) which mentions an eclipse of the moon that happened 11 days before the last battle between Darius and Alexander, in the month Boedromion. This eclipse is found, by calculation, to have coincided with the 446th olympic year, Sept. 20. It, therefore, the difference be computed between the 550th olympiad, *i. e.* the 217th olympian year, when the Persian empire began, and the 446th, when it ended, it will appear to have flourished 228 or 229 years.

EPOCHÀ, *Gelalaan*, called also *Royal Epochà*, and *Epochà of the Sultans*, began in the year of the Julian period 5787, A. D. 1074, on the 14th day of March, at the time of the equinox, and was established for the convenience of finding the vernal equinox, at which time the Persians celebrated their great feast, called *Neuruz*. See *Persian CALENDAR*.

EPOCHÀ of the establishment of the Roman Consular dignity. The republican form of government in Rome owed its origin to the tyranny of Tarquin the seventh king; in consequence of which the sovereign authority was divided, and two magistrates were elected under the denomination of consuls. The consular dignity was conferred on Brutus and Collatinus, 244 years after the building of the city. The names of the consuls were registered in the calendars until A. D. 541; and in the 15th year of Justinian the order was abolished. See CONSUL.

EPOCHÀ, *Julian*, or *Epochà of Julian years*, is the year of the Julian period 4668, answering to the year before Christ 46.

This epocha had its origin from the year of the reformation of the calendar under Julius Cæsar, called the "year of confusion."

EPOCHÀ, *Gregorian*. See GREGORIAN.

EPOCHÀ, *Spanish*, is the year of the Julian period 4676, answering to the year before Christ 38.

This era commenced at the time of the second division of

the Roman provinces among the Triumviri, and is reckoned from the 1st of January in the year 38 B. C. so that the first year of the Christian coincides with the 39th year of the Spanish era. The most famous synods of Spain and Africa have been distinguished and described according to the computation of this era; but by a decree of the council of Taragon, A. D. 1180, the Christian era was substituted in its room, though it continued in use till the year 1383. The Portuguese were the last people who computed by this era, and they gave it up A. D. 1415 or 1422. See ÆRA.

EPOCHÀ, *Adiac*, or *Adian*, is the year of the Julian period 4684, answering to the year before Christ 30, commencing in Egypt on the 29th day of August, and on the 1st of September among the Greeks of Antioch; but among the Romans on the 1st of January in the year of Rome 724.

EPOCHÀ of the Reformation. See REFORMATION.

For other epochas or eras, and the dates of remarkable events, see the table under CHRONOLOGY.

EPOCHETEUSIS, from ἐποχέτω, *I draw through a canal*, of ὄχετος, *canal*, a word used by Hippocrates, and others of the old writers in *Medicine*, to express the derivation of the blood, or juices, from one part to another.

EPODE, ἔπος, in *Lyric Poetry*, the third or last part of the ode; the ancient ode, or song being divided into strophe, antistrophe, and epode.

According to its most common acceptation, it signified a number of Lyric verses of different construction, comprised in a single stanza; and it was sung by the priests, standing still before the altar, after all the turns and returns of the strophe and antistrophe. The invention of epodes is ascribed to Archilochus.

The epode was not confined to any precise number, or kind of verses, as the strophe and antistrophe were; but when the ode contained several epodes, strophes, &c. they were all alike.

As the word epode, then, properly signifies the end of the song; and as in odes, what they called the epode finished the singing, it became customary, as M. Dacier shews, for any little verse which, being put after another, closed the period, and finished the sense which had been suspended in the first verse, to be called epode, ἐποδός.

And hence it is, that the sixth book of Horace's Odes is entitled "Liber Epodan, Book of epodes," because the verses thereof are all alternately long and short; and the short one, generally, though not always, closes the sense of the long one. The name of epode was likewise given to a small Lyric poem, composed of trimeters or iambs, of six feet, and dimeters of four feet alternately. Of this kind were the epodes of Archilochus, mentioned by Plutarch. But the signification of the word is extended still farther; epode being become a general name for all kinds of short verses, that follow one or more long ones; and in this sense, a pentameter is an epode, after an hexameter, which in respect thereof is a pro-ode.

EPODOS, from ἐπι, and ὄδη, *song*, in *Medicine*, a word used to express the curing of diseases by incantation.

EPOICODOMESIS, from ἐπι, and ὄδομαι, *I build upon*, in *Rhetoric*, is sometimes used for what is otherwise called climax.

EPOISSES, in *Geography*, a small town of France, in the department of the Côte d'Or, 9 miles W. of Semur.

EPOMIS, ἔπωμις, in *Anatomy*, the upper part of the shoulder, reaching up to the neck.

The word is Greek, ἐπωμις, which primarily signifies a short cloak or mantle made to cover the shoulders.

Some authors apply the word epomis to the upper part of

the os humeri; but the ancient Greek physicians only use it for the muscular, or fleshy part, placed as above mentioned. See DELTOIDES.

EPOMPHALION, from *επι, upon*, and *ομφαλος, navel*, any medicine which purges, on being applied to the navel.

EPOPOEIA, *Εποποιεα*, in *Poetry*, the history, action, or fable, that makes the subject of an epic poem.

The word is derived from the Greek *επος, carmen, verse*, and *ποιω, facio, I make*.

In the common use of the word, however, epopoeia is the same with epos, or epic poem itself: in which sense it is defined a discourse invented with art, or a fable agreeably imitated from some important action, and related in verse, in a probable and surprising manner; with a view to form the manners, &c. See *EPIC Poem*.

EPOPS, in *Ornithology*, a name by which some of the ancient writers have called the bird we call the upupa, or hoopoe. See *UPUPA*, of which it is a species.

EPORA, in *Ancient Geography*, a town of Spain, 28 miles from Castulon, according to the Itinerary of Antonine. Pliny calls it Ripepora. It is thought to be *Montoro* in the diocese of Cordova. M. D'Anville places it on the river Bætis, in Bætica, N. E. of Corduba.

EPOREDIA, *Ιβρέε* a town of Gallia Transpadana, situated towards the west, on the Doria Major.

EPOTIDES, in the *Ancient Ship-Building*, two large thick pieces of wood on each side of the prow of a galley, which resembled two ears, whence they had their name.

The epotides were chiefly designed to ward off the blows of the rōstra of the enemies' vessels.

EPPHA, or *Ερηα*, in *Ancient Geography*, a country of Arabia, in the vicinity of the Midianites.

EPPING, in *Geography*, a market town in the hundred of Waltham, in the county of Essex, England, is irregularly built, and consists of two parts or assemblages of houses; one round the church, called Epping Upland; the other, nearly a mile and a half south-east from the church, called Epping Street. The latter is by far the largest, and consists of one wide street, nearly a mile in length, situated on the high road from London to Newmarket, on a ridge of hills extending to a considerable distance north and south. Here a market is held on Fridays: the chief commodities exposed for sale, are butter and poultry, which are chiefly purchased for the use of the metropolis. At the west end of the street is a small new chapel: and near the middle are the shambles. The inns and public houses are numerous. Epping is 17 miles from London; contains, in both divisions, 315 houses, inhabited by 1726 persons; it has two annual fairs.

EPPING Forest, is an extensive tract of good woodland, deriving its present name from the town, but was formerly called Waltham Forest, and in very remote ages the Forest of Essex. Since it obtained the latter appellation, it has, however, been greatly curtailed, many thousand acres having been grubbed up, and the land cultivated. This forest is under the jurisdiction of a lord warden and four verderers: the wardenship is hereditary in the family of sir James Tilney Long, bart.: the verderers are elected by the freeholders of the county, and retain their offices during life. The forest rights are as various as the tenures of the different manors that surround it. In this forest, though so near to London, wild stags are yet found; and a stag is annually turned out on Easter Monday, under an establishment patronized by the principal merchants of the city. The hunt is well supported: the kennel for the hounds, and the building belonging to the hunt, have been lately erected at the expence of several thousand pounds.

At a small distance to the south-east is Hainault Forest, famous through many centuries for a venerable tree, called Fairlop Oak, which is remarkable for its size, and also for an annual fair held on the first Friday in July under its branches, which overspread an area nearly 300 feet in circumference: the stem, which is rough and irregular, measures 36 feet in girth. Morant's History of Essex. Beauties of England and Wales, vol. v.

EPPING, a town of Germany, in the archduchy of Austria; 4 miles S. of Aigen.

EPPING, a post town of America, in Rockingham county, New Hampshire, taken from the N. W. part of Exeter, and incorporated, in 1741. It contains 1121 inhabitants, and lies 6 miles N. W. of Exeter and 23 W. of Portsmouth.

EPPINGEN, a small town of the kingdom of Bavaria, in the palatinate on the river Elsatz, 21 miles N. E. of Philipsburg, and 18 miles N. W. of Heilbrun. N. lat. 49° 12'.

EPROUVETTE, is a machine, of which there are several varieties, used for proving the strength of gun-powder. The principle of this invention, in whatever form it may be applied, is to ascertain how far a certain measure or weight of gun-powder is capable of overcoming the resistance either of a certain weight, or of a spring, whose pressure against the explosion is computed. The former is evidently the most regular, and, consequently, the best adapted to military purposes, wherein the strength of the powder is often of the greatest moment, not only on account of the advantages gained by the greatest concentration of force, but because in the mortar and howitzer practice it is necessary to have a very accurate knowledge of the powers of expansion in the powder when ignited; by which means shells may be thrown, with the greatest precision, to any intended distance; whence the explosion takes the greatest possible effect.

In our arsenals, an eight inch mortar is ordinarily employed as an eprouvette: being charged with two ounces of powder, and an iron ball of sixty-four pounds, the latter should be projected at least 150 feet; the elevation of the piece being 45°, and the bed being placed perfectly horizontal. We consider this to be a fair standard; though some powder made from the best materials, and fresh from the mill will sometimes exceed even 180 feet; while, on the other hand, weak powder, that is, such as has not been kept very dry, or that has been re-stored, will rarely make a range equal to 120, and generally not exceeding even 110 feet.

The above mode of proof relates to cannon-powder; that intended for the use of musketry is ascertained by an eprouvette of a different description; namely, a musket barrel, of which the interior is highly polished. This should, with a charge of only four drachms, impel a steel ball through fifteen wet elm boards, each a quarter of an inch in thickness, and placed at  $\frac{1}{4}$  of an inch asunder; the first being 39 feet and 10 inches distant from the muzzle of the barrel. We must confess this exact number of inches in the distance, appears to be more fastidious than necessary, for we are apt to believe, that, in experiments of this nature, the odd two inches, necessary to complete the fortieth foot, would by no means derange the process.

The French eprouvette for cannon powder comes very close to our's, they using a brass ball of 60lb. (French weight) whose diameter is 7 inches and 9 points, or  $\frac{3}{4}$  of a line, (French measure) with one line of windage, (or space between the shot and the sides of the bore.) The chamber holds precisely three ounces; which quantity of their best powder will throw the ball full 180 yards; their re-stored powder throwing it about 160 yards. But Mons. Lombard's

lard's experiments give a result of 250 yards, with the powder now manufactured at the French mills; the eprouvette being always elevated to 45°.

Fine powder is sometimes tried by means of a small machine resembling a pistol, of which the barrel is very substantial, and the bore not more than the eighth of an inch in diameter. Over the barrel is a circular plate, acted upon strongly by a spring, which offers considerable resistance to the revolution caused therein, by the action of the powder on a projection which shuts down close upon the muzzle. The bore being filled with powder, and the wheel, or plate, turned so that its projection closes the muzzle, the explosion will, in proportion to its force, throw up the projection, and cause the wheel to revolve: the power of the powder is supposed to be ascertained by means of figures on the circumference, which indicate how much the wheel has been thrown round.

But such a machine cannot possibly give a correct standard; it being so subject to variation; as is also that contrivance which causes the powder to act underneath the hammer of a pistol lock. The pan being filled, the powder should have force enough to throw the hammer back. We need not comment on the uncertainty of such an estimate.

EPSOM, or EBBESHAM, in *Geography*, a parish and formerly a market town in the hundred of Coptorpe, Surrey, England, is fifteen miles S.E. from London. In the year 1800 it contained 414 houses, and 2404 inhabitants. The houses are disposed chiefly on two sides of a long wide street, or public road, and are situated on the west side of Banstead Downs. These are distinguished for their fine sweet verdure, which is mostly grazed by sheep; and the Banstead mutton is much esteemed for its flavour. On these downs are annual horse-races, which are much frequented by gamblers and sharpers, from the metropolis. The church, above a mile from the centre of the village, was served for many years by the late Rev. Jonathan Boucher, who died here in the year 1804. A large old seat near the church, called *Durdans*, was originally built by George, the first earl of Berkley, with the materials brought from the palace of Nonfuch, when that celebrated royal mansion was taken down. The first house being destroyed by fire, another was erected, and subsequently possessed by the earl of Guildford. Several other spacious seats, and pleasant villas, are found in the vicinity of Epsom, among which are Woodcote Park, the late lord Baltimore's; and Pit's-place, which receives its name from being situated within the excavation of a chalk pit. It is a singular and curious place.

EPSOM, a post town of America, in Rockingham County, New Hampshire, E. of Pembroke, adjoining, 10 miles E. of Concord, and 45 N. W. of Portsmouth. It was incorporated in 1727, and in 1800 contained 1034 inhabitants.

EPSOM Salt and Water. This so much celebrated salt was first extracted from the purgative mineral spring at Epsom in Surrey, which had long been celebrated for its medicinal qualities, by Dr. Nehemiah Grew in 1675, who published a treatise concerning it (*De Natura Salis Cathartici Amari*.) Dr. Grew gave it the appropriate name of sal catharticus amarus, or bitter purging salt; which is still retained, together with the names of Epsom salt, magnesia vitriolata, or sulphat of magnesia of modern chemical nomenclature; which see for the chemical properties of this salt.

The original Epsom salt, or that which was procured by the evaporation of the Epsom water, was sold in London at a very high price. Afterwards it was prepared, very extensively, by chemists of the name of Moulton, about the

year 1708, by evaporating the water of some springs at the foot of Shooter's-hill; which were found to resemble that at Epsom. Soon after it was discovered, as appears by Haukwitz, a celebrated trading chemist in London, that the same salt could be procured from the bitter of sea-water; and in a few years the secret transpired, and the same was prepared from sea-water at Portsmouth, Lymington, and at Newcastle; by which the salt from the Shooter's-hill springs was underfold, and the works were abandoned. Epsom salt was for a long time only prepared in this country, and the continent was supplied from hence; on which account it became known in Europe under the name of Epsom, or English salt; but Bergman afterwards discovered the same in the Sedlitz or Seydschutz waters in Bohemia, whence the name Sedlitz salt was added to its other appellations.

A considerable confusion prevailed for a long time between this salt and Glauber's Sal Mirabile (sulphat of soda,) the acid of both being the same, and the medicinal uses of each, and comparative doses, not materially differing. In fact it appears, that sometimes the true Glauber's salt was made small grained, by stirring it as it began to crystallize; and sometimes the true Epsom salt was made large grained to imitate Glauber's; and each was occasionally passed off for the other as either happened to be in most request. This kind of fraud indeed is still practised pretty extensively on parts of the continent where the Epsom salt is not easily procured. Some chemical difference between the two salts was very soon ascertained. Dr. Grew gives it as characteristic of the Epsom salt, that it coagulates with an alkali; but the nature of the earth that forms this coagulum, was not fully understood till the researches of Black and Bergman proved it to be the earth magnesia.

Epsom salt is a highly and justly esteemed purgative medicine, and is in very constant use. The taste is salt and bitter, attended, however, with a peculiar flavour approaching to sweetness. Notwithstanding its nauseous taste, it is often found to remain on the stomach when rhubarb and most other medicines are rejected, and in general it operates speedily, effectually, and without griping or debilitating. The usual dose for an adult is from half an ounce to an ounce; but it should be pretty largely diluted in gruel, broth, or any mucilaginous liquor.

EPSTEIN, in *Geography*, a small town of Germany, formerly in the Landgraviate of Hesse Darmstadt, but since the peace of Luneville, in the territory of the princes of Nassau Dietz. It is situated at no great distance from the confluence of the Rhine and Mayn, 18 miles N.W. of Francfort on the Mayn; and is chiefly remarkable for some good iron mines in its neighbourhood.

EPTACTIS, in *Natural History*, a name given by Linkius, and some other authors, to a species of star-fish, of the astrophyte kind, whose rays, or branches, at their first going out from the body, are only seven in number; but which very soon spread into more. See *STAR-fish*.

EPTAMERIDES, in *Music*, a name given by M. Sauveur to one of the intervals of his system, inserted in the Mem. de l'Acad. des. Sc. for 1701.

This author begins by dividing the octave into 43 parts or merides, then each of these into 7 eptamerides, so that the octave entire comprehends 301 eptamerides, which he still subdivides. (See *DECAMERIDE*.) The word is formed of  $\epsilon\pi\tau\alpha$ , seven, and of  $\mu\epsilon\rho\iota\varsigma$ , a part. In Sauveur's subdivision the octave is =  $23\frac{1}{10}\Sigma + 3\frac{1}{10}\Gamma + 3\frac{1}{10}m$ : and its common logarithm is = .9989999.0035. or .9990000.0000 according to the assumption of M. Sauveur, wherein the octave = .6990000.0000 and its reciprocal .3010, &c.

EPTE, in *Geography*, a small river of France in the

department of the Eure, which has its source near Bernay, and falls into the Seine below Vernon.

EPULÆ. See ENTERTAINMENTS.

EPULARES, in *Antiquity*, an epithet given to those who were admitted to the sacred epulæ or entertainments; it being unlawful for any to be present at them who were not pure and chaste.

EPULIS, (from *επι*, upon, and *ωλα*, the gums,) in *Surgery*, a tubercle on the gums. There are two kinds; one of a benign nature, and free from pain; the other more malignant, being very troublesome, and occasionally becoming, according to the descriptions of surgical writers, of a cancerous quality. Some of the excrescences are represented as having a narrow pedicle, while others are connected with the gum by means of a broad base.

The best plan of treatment consists in extirpating an epulis, as soon as the nature of the case manifests itself. The object may be accomplished either with caustic, or the knife. The latter mode is that, to which we should generally give the preference, because attended with the greatest degree of certainty, and not more pain.

Some writers advise us to tie the excrescence, when its neck is narrow. However, in such a case, the knife, or a pair of scissars, might also be very conveniently employed.

EPULO, in *Antiquity*, the name of a minister of sacrifice among the Romans.

The pontifices, not being able to attend all the sacrifices performed at Rome, to so many gods as were adored by that people, appointed three ministers, whom they called epulones, because they conferred on them the care and management of the epulæ; feasts in the solemn games and festivals.

To them belonged the ordering and serving the sacred banquet offered on such occasions to Jupiter, &c. They wore a gown bordered with purple, like the pontifices, their number was at length augmented from three to seven, and afterwards by Cæsar to ten.

Their first establishment was in the year of Rome 558, under the consulate of L. Furius Purpureo, and M. Claudius Marcellus.

EPULOTICS, (from *επουλω* to cicatrize), in *Surgery*, topical applications, which dispose wounds and ulcers to heal.

EPULUM, in *Antiquity*, banquet, a holy feast prepared for the gods.

The statues of the gods were commonly laid upon a bed, and served in the epula, as if they had been very hungry; to perform which was the function of the ministers of sacrifice, hence called epulones.

EPWORTH, in *Geography*, a market town in Lindsey division of Lincolnshire, England, is situated 158 miles from London: it is built in a straggling irregular manner; and contains, according to the late population return, 275 houses, and 1434 inhabitants, who are chiefly employed in spinning hemp and flax, of which great quantities are grown here, and in the manufacture of sacking and bagging, which is the chief trade of the town. A weekly market is held on Thursdays, and two fairs annually. Quantities of large oaks, firs, and other trees, some of which appear to have been burnt, and others cut down, are frequently found here three feet beneath the surface of the earth. The rectory of Epworth was held by the Rev.

Samuel Wesley, the father of the distinguished leaders of the Arminian Methodists, John and Charles Wesley.

EQUABLE MOTION, is that whereby the moveable body proceeds with the same continued velocity; neither accelerated nor retarded.

EQUABLE Pulse. See PULSE.

EQUABLE Style. See STYLE.

EQUABONA, in *Ancient Geography*, a town of Spain, in Lusitania, according to the Itinerary of Antonine, situated on the left side, and at the mouth of the Tagus, not far from the sea.

EQUAL, a term of relation between two or more things of the same magnitude, quantity, or quality.

Wolffius defines equals to be those things which may be substituted for each other, without any alteration of their quantity. It is an axiom in geometry, that two things which are equal to the same third, are also equal to each other. And again, if to or from equals you add or subtract equals, the sum or remainder will be equal.

EQUAL Altitudes, in *Practical Astronomy*. One of the most practicable and certain methods of determining the time, and thus ascertaining the error of a clock or chronometer, is by observing equal altitudes of the sun, or of a fixed star. For this purpose all that is necessary is to observe the instant the sun or star is at any altitude towards the east, before the meridian passage; and the instant must likewise be marked when the same object attains exactly the same altitude towards the west, after the meridian passage: the mean between the above quantities will be the instant marked by the clock at the moment the sun or star was on the meridian. The preceding operation, however, supposes, that the declination of the object has not varied during the elapsed interval, but this with the sun seldom happens. The observation, therefore, must be corrected by a table, or by a direct calculation.

Let P (*Plate XII. Astronomy, fig. 106.*) be the elevated pole, Z the zenith, S the sun, S B an arc parallel to the horizon H O, so that the points B and S have the same altitude; P S the polar distance of the sun in the morning, P B its polar distance in the evening (supposed to have become less). When the sun in the afternoon arrives at the point B, whose altitude suppose 20°, the same as the morning, the hour angle Z P B, or the distance of the sun, and its hour angle from the meridian P Z, will be greater than the morning hour angle Z P S. We have, therefore, two triangles, Z P S, Z P B, which have each the side P Z common, and the sides Z S, Z B, each equal to 70°, since they are the complements of the altitudes, 20° in each case. The sides P S, P B, differ by a quantity which is equal to the change of the sun's declination in the interval between the two observations. If the two triangles be resolved separately, the two hour angles will be found different: the half of this difference is the correction, which must be applied to the middle point of time to obtain the exact instant of the sun's passage over the meridian. This correction is given in the annexed table, which is taken from the last edition of La Lande's *Astronomy*. It is calculated from the following differential analogy.

$$\frac{\delta \times (\text{tang. latitude} \pm \text{tang. dec. } \odot)}{30 (\text{sin. hour-angle} \pm \text{tang. hour-angle})}$$

# EQUAL.

## TABLE OF EQUATION OF EQUAL ALTITUDES.

Argument  $\frac{1}{2}$  the elapsed Time.

☞ Multiply the Tangent by the Latitude, and if it is South, change the Signs.

*Equal-Altitude Instrument*, is an instrument used in *Astronomy* for ascertaining the exact time at any place, by means of equal altitudes of any heavenly body, as observed successively at the opposite sides of the meridian. Formerly, the instrument used exclusively for this purpose was a refracting telescope of considerable length, attached to a vertical axis of motion, placed truly perpendicular to the horizon by means of a plumb-line or spirit-level, so that when the telescope had a given elevation, it might be fixed at that elevation, and describe a parallel of altitude as the vertical axis turned round; which method was equally simple and accurate, as it required no graduated circles for reading either horizontal or vertical angles; but then its utility was limited to the single operation of determining the instant when any celestial body on the western side of the meridian had the same altitude that it had at a given instant on the eastern side, and hence the intermediate instant when the said body was on the meridian, provided its declination had not sensibly altered during the interval. But in the present improved state of astronomical and nautical instruments, almost any of them will measure equal altitudes with great precision, and at the same time indicate the quantity of the altitudes observed, so that an instrument to take equal altitudes only is no longer a desideratum, and its origin and construction may now be considered as matter of curiosity, or as a link in the historical chain of astronomical instruments, but yet at the time was a link of great importance. When sir Isaac Newton presented to the observatory at Trinity college, Cambridge, an excellent pendulum clock for the use of the professor, it became a matter of great importance to have the ready means of adjusting the rate of the clock to exact time; professor Cotes, therefore, contrived an equal-altitude instrument, which was made at very little expence, and which yet fully answered its purpose. This instrument is described in Dr. Robert Smith's *Optics*, and also another, which is an improvement on it, as being at that time in the possession of the earl of Ilay. As we presume it will not be unacceptable to our readers to see how an instrument, that does not indicate any measure, will yet determine equal altitudes with accuracy, we shall give in succession brief descriptions of the two instruments we have already named, accompanied by corresponding figures.

*Professor Cotes' Equal-altitude Instrument*.—*Fig. 3. of Plate XVII. of Astronomical Instruments*, is a representation of Mr. Cotes' equal-altitude instrument, as applied in taking an observation. AB is a strong wooden axis in a vertical position about six feet long, and having the extreme ends of well-tempered steel; the superior end A has a cylindrical pivot, and the lower end a conical one, both resting in adjustable pieces of metal, that are not necessary to be described; two strong bars, CD and DE, are firmly attached to the axis, so as to form a right angle where they are united at D; in like manner two other bars are fixed together and to the axis, namely, GF and FE, making a right angle at F; and below these a thick pin Y passes quite through the axis. Near the top at T is a piece of tapped wire screwing into the axis, and supporting a plumb-line TV, which falls at the point of a fine needle inserted a little out of the centre of the thick pin Y; so that by turning this wooden pin round, the needle point may be brought into contact with the line whenever it does not touch it: the bar CD has half a dozen tapering pins or pegs turned round, inserted into holes at equal distances, or nearly so, and the bar EF has one such pin. The pin at F supports the lower end of the telescope PQ, and the upper or object end hangs by one of the six pins on the arm CD, as the elevation in any observation may require; the piece

ILKM, that carries the peg N, by which the telescope hangs, being made fast to its tube. The telescope, not being an achromatic at that time, was five feet long, and therefore required the axis of motion to be at least six feet. When the pivots of the axis were nicely adjusted with respect to east and west, and also to north and south, which was known by the plumb-line hanging in apparent contact with the needle point, during the whole of an entire revolution, then the object-end of the telescope described an exact parallel to the horizon, or parallel of altitude, and whatever bodies appeared in the centre of the eye-glass, which we suppose to have been a single one, had all equal apparent altitudes.

*The Earl of Ilay's Equal-altitude Instrument*.—The instrument said to have been in the possession of the earl of Ilay, is represented by *fig. 4. of Plate XVII.* We know not who was the maker, otherwise we should have given his name in preference. The axis *ab* is of steel squared, thirty inches long; the upper end of it, *a*, bears a sextantal arch *cd*, fixed at *a* immoveably; the telescope N is thirty inches long also, and is moveable together with its graduated semi-circle round the same point *a* as a centre of motion: this semi-circle may be fixed to the sextantal arch at any elevation of the telescope, by the finger-nuts *c* and *d*, passing through the circular aperture of the semi-circle, and screwing into the sextantal arch. Immediately under the semi-circle is a spirit-level *lm*, with screws of adjustment, and at *e* under it, the axis, for a short way down, is cylindrical, about an inch in diameter, and well-polished. The lower end of the axis is conical, and the eye-piece of the telescope has in its focus five vertical wires at equal distances, parallel to each other, and two parallel cross wires, as represented in *fig. 5.* When the instrument here described is used, its axis is let down into a stand of the shape of a long hollow parallelepiped, wanting two sides. Its other sides *f, g*, are a couple of brass plates, equal in length to the part *be* of the axis, and are screwed together edgeways, but the centre of the upper square end piece *b*, four inches square, is a round hole, just large enough to receive without touching it, and over this hole is fixed another plate with a triangular hole, concentric, one of the sides of which triangle is moveable by an adjustment screw, to make the cylinder bear alike on all sides: on the lower square, or base *i*, lies another adjustable piece, with a fine conical hole to bear the point *b* of the axis, and to adjust the axis vertical by means of its screws, as pointed out by the level. The frame, thus furnished with the instrument, is then firmly fastened to a solid pillar K, by means of a niche made in it to receive the brass plates. The axis is known to be truly perpendicular when the bubble of the level will remain in the middle of the tube during every part of an entire revolution of the axis. If the axis of this instrument were to be placed parallel to the earth's axis, and in the true meridian, its construction is equally adapted for an equatorial telescope, in which case the semi-circle would in every situation be a secondary to the equator, or would measure declinations. The cross wires in the telescope are very useful for taking five pairs of observations, from which a mean may be taken with greater accuracy than one pair of observations alone would give, and in cloudy weather will afford five chances of seeing the body at the proper instants of required altitude. For the methods of applying the corrections for equal altitudes, and of ascertaining the exact time as deduced from the observations, the reader is requested to consult our article *CHRONOMETER*, where the requisite problems are exemplified. It is scarcely necessary to add, that a common Hadley's sextant or octant is a good instrument

# EQUAL.

instrument for taking equal altitudes, provided the observer have a good artificial horizon, when his observations are taken on the land; the imperfection of the graduations being of no importance, except when the exact measure is wanted for other purposes.

**EQUAL Angles**, are those whose containing lines are inclined alike to each other; or which are measured by similar arches of their circles.

**EQUAL Arches**. See ARCH.

**EQUAL Arithmetical Ratios**, are those wherein the difference of the two less terms is equal to the difference of the two greater. See RATIO.

**EQUAL Circles**, are those whose diameters are equal. See CIRCLE.

**EQUAL Curvatures**, are such as have the same or equal radii of curvature. See CURVATURE.

**EQUAL Figures**, are those whose areas are equal, whether the figures be similar or not.

The segments of a sphere, or circle, are of an equal concavity, or convexity, when they have the same ratio, or proportion to the diameters of the spheres, or circles, whereof they are parts.

**EQUAL Geometrical Ratios**, are those whose least terms are similar, aliquot, or aliquant parts of the greater.

**EQUAL Hours**. See HOUR.

**EQUAL Hyperbolas**, are those, all whose ordinates to their indeterminate axes, are equal to each other; taken at equal distances from their vertices.

**EQUAL Solids**, are those which comprehend, or contain, each as much as the other; or whose solidities, or capacities, are equal. See SOLID.

**EQUAL Beating**, in *Music*, is said of such tempered concords as beat equally quick, or make the same number of *wa, wa, wa, wa's*, in a given space of time, when sounding. The first who mentions, or makes any use of equal-beating concords, is Dr. Robert Smith, who observes, (*Harmonics*, p. 188.) "if several imperfect consonances of the same name, as Vths, for instance, (by which the whole scale is usually tuned,) beat equally quick, they are not equally harmonious, or tempered; to make them so, the higher in the scale ought to beat as much quicker than the lower, as their bases vibrate quicker (prop. xi. cor. 2.); that is, if a Vth be a minor tone higher than another, it should beat quicker, in the ratio of 10 to 9, or (if a major tone) 9 to 8 nearly; if a IIIId higher, in the ratio of 5 to 4; if a Vth higher, in the ratio of 3 to 2; if an VIIIth higher, of 2 to 1, &c.

In schol. 2. to prop. xx., the doctor gives a table of beats to be made in fifteen seconds of time, by four successive 5ths above C respectively, in order to form a system for the common instruments with twelve notes in an octave, wherein every IIIId shall beat sharp, as fast as the Vth to the same base beats flat: let it be observed, however, that this will not be the case in the IIIIds or Vths affected by the beating notes, or resulting 5th, after this method has been pursued through eleven 5ths.

In the same table we have the number of beats for the above succession of 5ths, so calculated, that the Vths and VIths to the same base may beat equally quick, the former flat, and the latter sharp; which will give the notes of the doctor's system of equal harmony in three octaves, as far as the same can be applied on a defective or douzeave instrument. At page 220, mention is made of another equal-beating system, wherein the IIIIds and VIths to the same base beat equally quick, and which is said to approach so near to the system of equal harmony, as not to need a particular table.

VOL. XIII.

In the directions given by earl Stanhope, pages 13 and 14, of his stereotype "Principles of the Science of Tuning," for adjusting his two successive biequal 3ds, and three successive triequal quint; his lordship directs that these shall be made to beat equally quick respectively; and falls into the mistake of supposing that this would produce the equal temperament of those IIIIds and the Vths respectively, that he had previously calculated for them, by mean proportionals, for his monochord system, contrary to the demonstrations of Dr. Smith above; and in a printed "Letter to the Duke of Cumberland respecting the Stanhope Temperament," this error being persisted in, after it had been pointed out by Mr. Farey in the *Philosophical Magazine*, vol. xxvii. p. 203, it becomes necessary for us to point out (as could not be done under BIEQUAL Third, in our work), that the ratios  $\frac{4}{3}$ ,  $\frac{1}{3}$ , and  $\frac{1}{2}$ , exactly represent the notes F, b A and c respectively, when the two successive 3ds (which his lordship calls biequal) E, b A and b A c, whose ratios are  $\frac{1}{3}$  and  $\frac{1}{2}$ , make an equal number of beats in a second of time; and this number of beats, when C makes 240 complete vibrations in 1", is exactly ten times in a second. Thus we see, that there are three different intervals, called

by his lordship biequal thirds, whose ratios are  $\frac{1}{2}$ ,  $\frac{\sqrt{10}}{4}$ , and  $\frac{1}{3}$ , and their common logarithms are .8985423.5924, .8979400.0867, and .8973376.5811 respectively, or in the new notation  $206.228 \Sigma + 4f + 18 m$ ,  $207.5 \Sigma + 4f + 18 m$ , and  $208.772 \Sigma + 4f + 18 m$  nearly respectively: and there are, indeed, others which arise from the new instructions which his lordship gives in the letter to the duke of Cumberland above referred to, for tuning equally-tempered concords by means of the *absence* of "beating between the two beatings;" which new species of equal beating is considered in the *Philosophical Magazine*, vol. xxxiii. p. 297, and is shewn to produce other intervals than the above, and which yet come under the appellation of biequal thirds, as desired by earl Stanhope.

**EQUAL Harmony**, has been applied by Dr. Robert Smith to the different concords V, VI, and III, (or their complements 4th, 3d, and 6th,) when they are so tempered, as to be equally harmonious or pleasant to the ear, as tempered concords; and the result of his laborious calculations for forming a system, wherein every concord within the compass of three octaves shall be equally and the most harmonious, (*Harmonics*, p. 140.) is, that each V, VI, and III, are to be tempered  $\frac{-5}{18}$ ,  $\frac{+3}{18}$ , and  $\frac{-2}{18}$  parts of a major comma respectively: or, in a system of four octaves of equally harmonious concords, these temperaments are to be  $\frac{-11}{40}$ ,  $\frac{+7}{40}$ , and  $\frac{-4}{40}$  parts of a comma for the V, VI, and III, respectively. But it is to be observed, that these temperaments are applicable only to instruments with 21 strings, or pipes, in each octave, and not to the common piano-fortes, organs, &c. in use, with only 12 strings, or pipes, of different pitches within the compass of an octave.

The term equal harmony has been, as we think, improperly applied by Mr. Emerson, and others, to the *isotonic* or *equal temperament* system of intervals (which see); it being observable that Dr. Smith's design is to effect an equal harmony among the different concords, and the equal temperament makes an equal harmony among the different keys, which are in effect very different systems, and ought not to bear the same name.

Equal harmony also denotes the tuning by perfect 5ths without temperament, making all the keys participate equally

equally of the imperfection of the scale on keyed instruments. By this method of tuning, the thirds will, at first, seem very harsh and crude; but by a little use the ear will accommodate itself to the evil, and indulge the abbé Rousfier, or his makes, with the triple progression, by which Pythagoras formed the scale, and by which the Chinese, in the most remote antiquity, according to Pere Amiot, produced the few sounds with which their imperfect scale is furnished. See TEMPERAMENT and TRIPLE Progression.

EQUAL Temperament, is a system of twelve intervals within an octave, all equal to each other; each of which

has the ratio of  $\sqrt[12]{2} = 512 + f + 412^5 m$ , (see Philosophical Magazine, vol. xxix. p. 347.) the common logarithm of each of such mean semitones being = .9749141.6703. This system is often called the isotonic, and sometimes that of Merlennus, by M. Couperin, M. Marpurg, Mr. Emerson, Mr. Cavallo, Mr. Davis, and others, who have written in its favour. Dr. Robert Smith, who disapproves of this system, states the temperaments of its V and 4th, its VI and 3d, and its III and 6th, to be  $\frac{7}{8}$ ,  $\frac{7}{8}$ , and  $\frac{6}{7}$  parts of a major comma respectively (Harmonics, p. 167.), but these are incorrect, and ought to have been  $\frac{1}{17}$ ,  $\frac{1}{17}$ , and  $\frac{6}{17}$  of a comma, the temperaments of these concords, very nearly, as stated in the first column of Tab. II. page 158, of the same work. Mr. Emerson, in his "Algebra," prob. ccii. calculates the beats which the concords in this system make, in the octave above the G of the bass clef, and states these at - 15, + 11, + 1, - 1, - 18, and + 13 in one second of time, made by the 3d, III, 4th, V, 6th, and VI respectively, the flat temperaments being marked - and the sharp ones +.

The equal temperament of Mr. Farey, (Philosophical Magazine, vol. xxviii. p. 65, and xxx. p. 6.) differs only in an insensible degree from the above, his half note being  $512 + f + 5m$  between the notes C and b D, b E and E, F and b G, G and b A, and b B and B; and  $512 + f + 4m$  between the notes b D and D, D and b E, E and F, b G and G, b A and A, A and b B, and B, &c.; yet this very slight variation enables an organ tuner to tune the twelve notes of this system, by help of certain combinations of perfect Vths, 4ths, and IIIs! In this method of obtaining an equal temperament, the successive 5ths C G, G D, D A, A E, E B, B b G, G b D, and D b A, are to be tuned upwards, each by ascending (on a spare range of pipes or different stop to the one intended to be tuned) five successive perfect 4ths, and from the highest note of these descending two perfect 5ths and one major 3d, which last or lowest note is to be transferred to the G of the stop intended to be tuned. From this same note, G, five 4ths up, and two V + III down, are to be tuned to get D, and so on to b A. The remaining 5ths c F, F b B, and b B b E, are to be tuned downwards, by descending from c five successive 4ths, and thence ascending two Vths and a III to obtain F, from which note, repeating the same process until the note b E is obtained; when, if the operations have been carefully performed, and no beats suffered to remain in any of the perfect 4ths, 5ths, 3ds, or unisons, or in the octave C c, &c. the resulting 5th, or that between the beating notes b A and b E, will be found, but in an almost insensible degree flatter than all the other fifths in the scale; the difference being only m, or less than  $\frac{1}{1300}$ th part of a major comma! between this V and each of the other eleven Vths: this being  $3572 + 7f + 30m$ , and each of the others  $3752 + 7f + 31m$ . The logarithm of the first or largest of the half-notes in this system is = .9749119.1920, and of the smallest .9749157.7262. See TEMPERAMENT.

EQUAL, in Optics. We say, that things seen under equal angles are equal. Equal parts of the same interval, or magnitude, if unequally distant from the eye, appear unequal. Equal objects, and at equal distances, only the one placed directly, and the other obliquely, seem unequal; and that placed directly, the bigger.

Masonry by EQUAL Courses. See MASONRY.

EQUALITY, in Algebra, is a comparison of two quantities, that are equal both really and representatively, i. e. which are so both in effect and letters.

A comparison of two quantities equal in effect, but unequal in letters, to render them equal, is called an equation, which see.

EQUALITY is usually denoted by two parallel lines, as = : thus  $2 + 2 = 4$ , i. e. 2 plus 2 are equal to 4. This character was first introduced by Robert Recorde. Des Cartes, and some after him, in lieu thereof, use  $\propto$ : thus,  $2 + 2 \propto 4$ ; so  $z - y \propto b + c$ ; signifies that z minus y is equal to b plus c.

From an equation we arrive at an equality, by changing an unknown letter into another, whereby the two members of the equation, i. e. the two quantities compared together, and connected by the sign of equality, are rendered equal.

Thus, in the equation  $a x = b c d$ ; supposing  $x = \frac{bcd}{aa}$ , we change x into  $\frac{bcd}{aa}$ , and by this substitution arrive at the equality  $bcd = bcd$ .

In the solution of a numerical problem, which is to be rendered rational, if there be only one power to be equalled to a square, or other higher power, it is called simple equality.

Where there are two powers to be equalled, each to a square, it is called double equality, &c.

Diophantus hath given us a method for double equalities, and F. de Billy, another for triple equalities, in his Diophantus Redivivus.

EQUALITY, in Astronomy. Circle of EQUALITY, or the equant. See CIRCLE and EQUANT.

EQUALITY denotes the exact agreement of two or more things in respect of quantity. Thus, figures are equal which may occupy the same space, by the fluxion or transposition of their parts. See on this subject an elaborate dissertation by Dr. Barrow, in the 11th and 12th of his Mathematical Lectures.

EQUALITY, ratio, or proportion of, in Geometry, is that between two equal numbers, or quantities.

Proportion of EQUALITY evenly ranged, or ex aequo ordinata, is that in which two terms in a rank, or series, are proportional to as many terms in another series, compared to each other in the same order, i. e. the first of one rank to the first of another; the second to the second, &c.

Proportion of EQUALITY evenly disturbed, called also ex aequo perturbata, is that in which more than two terms of one rank are proportional to as many terms of another compared to each other, in a different and interrupted order; viz. the first of one rank to the second of another; the second to the third, &c.

EQUALITY, Union of. See UNION.

EQUALITY, in Law, the law delights in equality; so that when a charge is laid upon one, and divers ought to bear it, he shall have relief against the rest. 2 Rep. 25.

EQUANIMITY, in Ethics, denotes an even, uniform temper of mind, amidst all the varieties and revolutions of time and chance. This virtue, together with prudence, forms the character which Horace gives of Aristippus:

"Omnis

“Omnis Aristippum deceit color & status & res.”

**EQUANT, or ÆQUANT,** in *Astronomy*, a circle, formerly imagined by astronomers, in the plane of the deferent, or eccentric; for regulating and adjusting certain motions of the planets, and reducing them more easily to a calculus. See **APOGEE, CIRCLE, DEFERENT, and EXCENTRIC.**

**EQUATED ANOMALY.** See **ANOMALY** and **ELLIPTIC Motion.**

**EQUATED Bodies.** On Gunter's sector there are sometimes placed two lines, answering to one another, and called the lines of equated bodies: they lie between the lines of solids, and superficies, and are noted with the letters D, I, C, S, O, T, for dodecahedron, icosaedron, cube, sphere, octahedron, and tetrahedron.

The uses of these lines are, 1. When the diameter of the sphere is given, to find the sides of the five regular bodies, severally equal to that sphere. 2. From the side of any of the bodies being given, to find the diameter of the sphere, and the sides of the other bodies, which shall be equal severally to the first body given.

If the sphere be first given, take its diameter, and apply it over in the sector in the points S, S: if any of the bodies be first given, apply the side of it over in its proper points; so the parallels taken from between the points of the other bodies shall be the sides of those bodies, equal severally to the first body given.

**EQUATION,** in *Algebra*, is when two equal quantities, differently expressed, are compared together, by means of the sign = placed between them.

Thus,  $9 - 4 = 5$ , is an equation expressing the equality of  $9 - 4$  and  $5$ ; and  $a + b - c = d$ , is an equation denoting that the difference between the sum of  $a + b$ , and  $c$ , is equal to  $d$ ; the quantities between which the sign = is placed being called the two sides of the equation.

It is sometimes customary, however, to place all the quantities on one side of the equation, and to make them equal to 0, or zero, on the other side; as  $a - b = c$ , or  $a + b - c = 0$ , &c. which is only setting down the difference of two equal quantities and putting it equal to 0.

The terms of an equation, are the several quantities or parts of which it is composed: thus, in the equation  $a + b = c$ , the terms are  $a$ ,  $b$ , and  $c$ ; and the sense or meaning of the expression is, that some quantity represented by  $c$ , is equal to the sum of two others, represented by  $a$  and  $b$ .

When a quantity stands alone, on one side of an equation, the terms on the other side are said to be a value of that quantity. Thus, in the equation  $x = a - b$ , the difference of the two numbers represented by  $a$  and  $b$  is called the value of  $x$ .

Equations are also distinguished by the denominations of *simple* and *compound*, or, as they are frequently called, *simple* and *affected*; which latter term, however, it would be better to discard, as being less natural and appropriate than that of *compound*.

A *simple equation*, is that which contains only one power of the unknown quantity; as  $x + a = b$ , or  $a x^2 + b = c$ , or  $2 x^3 + 3 a^2 = 4 b$ , &c. where  $x$  denotes the unknown quantity, and the other letters or figures such quantities as are known.

A *compound equation*, is that which contains two or more powers of the unknown quantity; as  $x^2 + a x = b$ , or  $x^3 + a x^2 - b x = c$ , &c.

Equations are likewise divided into different orders, according to the highest power of the unknown quantity contained in any one of their terms; as *quadratic*, *cubic*, *biquadratic*, &c. thus,

A *quadratic equation*, is that in which the unknown quantity rises to two dimensions, or that contains both the unknown quantity and its square; as  $x^2 + 10 x = 30$ , or  $a x^2 + b x = c$ .

A *cubic equation*, is that in which the unknown quantity is of three dimensions, or that rises to the cube or third power; as  $x^3 - 3 x = 1$ , or  $x^3 + 2 x^2 = 4$ , or  $a x^3 + b x^2 + c x = d$ .

A *biquadratic equation*, is that in which the unknown quantity is of 4 dimensions, or that rises to the fourth power; as  $x^4 + 2 x = 5$ , or  $x^4 + 3 x^2 = 10$ , or  $x^4 + 4 x^2 + 7 x = 50$ , or  $a x^4 + b x^3 + c x^2 + d x = e$ . And so on, for the 5th, 6th and other higher order of equations; which are all denominated according to the highest power of the unknown quantity contained in any one of their terms.

The *root of an equation*, is that quantity, whether positive, negative, or even imaginary, that when substituted for the unknown quantity, will make both sides of the equation vanish, or become equal to 0.

Thus, in the equation  $x^2 - 6 x = 72$ , either  $+ 12$  or  $- 6$  is a root, or value, of the unknown quantity; for if each of these numbers be separately substituted for  $x$ , they will be found to satisfy the conditions of the equation.

In the resolution of an equation, containing only one unknown quantity, several previous operations are often required to be performed, in order to adapt it to the rule to which it belongs; the greater part of which may be performed by means of a few self-evident and obvious principles; namely, that if equal quantities be added to, or subtracted from, equal quantities, the sums or remainders will be equal; if equal quantities be multiplied or divided by the same quantity the products or quotients will be equal; or if equal quantities be raised to the same power, or have the same root extracted, the results will still be equal.

From these simple considerations are derived the following rules, which will equally apply to equations of all orders, and are alone sufficient for the resolution of simple equations.

**Rule 1.**—Any quantity may be transposed from one side of the equation to the other by changing its sign.

Thus, if  $x - 5 = 8$   
Then  $x = 8 + 5$   
Or  $x = 13$   
And if  $4 x - 8 = 3 x + 7$   
Then  $4 x - 3 x = 7 + 8$   
Or  $x = 15$

From this rule it also follows that if any quantity be found on each side of the equation, with the same sign, it may be left out of both. And that the signs of all the terms of an equation may be changed into the contrary ones, without affecting the truth of the equation.

Thus, if  $x + 2 = 7 + 2$   
Then  $x = 7$   
And if  $a - x = b - c$   
Then  $x + a = c - b$   
Or  $x = a + c - b$

**Rule 2.**—If the unknown quantity, in an equation, be multiplied by any quantity, that quantity may be taken away, by dividing all the rest of the terms by it.

Thus, if  $7 x = 49$   
Then  $x = \frac{49}{7} = 7$   
And if  $a x = b - c$   
Then  $x = \frac{b - c}{a}$

**Rule 3.**—If any term of an equation be a fraction, its denominator

# EQUATION.

nominator may be taken away, by multiplying all the rest of the terms by it.

$$\text{Thus, if } \frac{x}{2} = 3$$

$$\text{Then } x = 6$$

$$\text{And if } \frac{x}{u} - b = c$$

$$\text{Then } x - ab = ac$$

$$\text{Or } x = a(b + c)$$

Or the denominators may be taken away from several terms of an equation, by one operation, if all the terms be multiplied by any number which is a multiple of each of the denominators.

$$\text{Thus, if } \frac{x}{2} + \frac{x}{3} + \frac{x}{4} = 6$$

Then, if all the terms be multiplied by 12, which is a multiple of 2, 3 and 4,

$$\text{We shall have } 6x + 4x + 3x = 72$$

$$\text{And } 13x = 72$$

$$\text{Or } x = \frac{72}{13} = 5 \frac{7}{13}$$

It also appears, from this rule, that if each of the terms of an equation be either multiplied or divided by the same quantity, that quantity may be left out of them all.

$$\text{Thus, if } ax = ab + ac$$

$$\text{Then } x = b + c$$

$$\text{And if } \frac{x}{a} + \frac{b}{a} = \frac{c}{a}$$

$$\text{Then } x + b = c$$

$$\text{Or } x = c - b$$

4. If the unknown quantity, in any equation, be in the form of a surd, let it be made to stand alone on one side of the equation, and the remaining terms on the other; then involve each side to a power denoted by the index of the surd, and the quantity will thus be rendered free from any surd expression.

$$\text{If, for example, } \sqrt{x + 2} = 5$$

$$\text{Then, by transposition, } \sqrt{x} = 5 - 2 = 3$$

$$\text{And, by squaring both sides, } x = 9$$

$$\text{In like manner, if } \sqrt{x^2 + a} - x = b$$

$$\text{Then, by transposition, } \sqrt{x^2 + a} = b + x$$

$$\text{And by squaring } x^2 + a = b^2 + 2bx + x^2$$

$$\text{And by leaving out } x^2 \text{ on each side } a = b^2 + 2bx$$

$$\text{Or } a - b^2 = 2bx$$

$$\text{Or } x = \frac{a - b^2}{2b}$$

5. Any analogy, or proportion, may be converted into an equation, by making the product of the two extremes equal to that of the two means.

$$\text{Thus, if } 3x : 16 :: 5 : 7$$

$$\text{Then } 3x \times 7 = 16 \times 5$$

$$\text{Or } 21x = 80$$

$$\text{Or } x = \frac{80}{21} = 3 \frac{17}{21}$$

Having thus shewn the manner in which a simple equation, containing only one unknown quantity, may be solved, it will be proper, in the next place, to explain the methods by which two or more equations of this kind may be reduced to a single one, and thence resolved by some of the foregoing rules; observing, in this case, that there must always be the same number of equations as there are unknown quantities, otherwise the question will admit of a variety of answers.

The principal methods, made use of for this purpose, as far as regards the resolution of two simple equations, are the three following:

1. Observe which of the unknown quantities is the least involved, and find its value in each of the two equations by the methods already explained.

This being done, let the values, thus found, be put equal to each other; and there will arise a new equation, with only one unknown quantity in it, the value of which may be found as before.

As an example in this case, let it be required to determine  $x$  and  $y$  from the two following equations.

$$2x + 3y = 23$$

$$5x - 2y = 10$$

$$\text{Then, from the 1st equation } x = \frac{23 - 3y}{2}$$

$$\text{And from the 2d, } x = \frac{10 + 2y}{5}$$

Hence, if these two values be put equal to each other,

$$\text{We shall have } \frac{10 + 2y}{5} = \frac{23 - 3y}{2}$$

$$\text{Or } 20 + 4y = 115 - 15y$$

$$\text{Therefore } 15y + 4y = 115 - 20$$

$$\text{Or } 19y = 95$$

$$\text{And consequently } y = \frac{95}{19} = 5$$

$$\text{And } x = \frac{10 + 2y}{5} = \frac{10 + 10}{5} = \frac{20}{5} = 4$$

2. Consider which of the unknown quantities you would first exterminate, and find its value in that equation where it is the least involved.

Then substitute this value for its equal in the other equation, and there will arise a new equation, with only one unknown quantity in it, the value of which may be found as before.

Thus, taking the same example as in the former rule.

$$2x + 3y = 23$$

$$5x - 2y = 10$$

$$\text{Then, from the 1st equation, } x = \frac{23 - 3y}{2}$$

And, if this value be substituted for  $x$  in the 2d equation, we shall have

$$5\left(\frac{23 - 3y}{2}\right) - 2y = 10$$

$$\text{Or } 115 - 15y - 4y = 20$$

$$\text{And consequently } 115 - 20 = 15y + 4y$$

$$\text{Or } y = \frac{95}{19} = 5$$

$$\text{And } x = \frac{23 - 3y}{2} = \frac{23 - 15}{2} = \frac{8}{2} = 4$$

3. Let the given equations be multiplied or divided by such numbers or quantities as will make the term which contains one of the unknown quantities the same in both equations.

Then, by adding or subtracting the two equations, as occasion may require, there will arise a new equation with only one unknown quantity in it, which may be resolved as before.

Thus, taking the same example as in the two former methods.

$$2x + 3y = 23$$

$$5x - 2y = 10$$

Then, to exterminate  $x$ , let the first equation be multiplied by 5, and the 2d by 2, and we shall have

# EQUATION.

$$10x + 15y = 115$$

$$10x - 4y = 20$$

And subtracting the latter of these two equations from the former, the result will be

$$19y = 95$$

And consequently  $y = \frac{95}{19} = 5$

And if this be substituted for  $y$  in the last of the two given equations, we shall have

$$5x - 2 \times 5 = 10$$

$$\text{Or } 5x = 10 + 10 = 20$$

$$\text{Or } x = \frac{20}{5} = 4$$

As another example of this third method, which is commonly more easy and expeditious in practice than either of the other two,

Let there be given  $\begin{cases} ax + by = c \\ dx + fy = g \end{cases}$  to find  $x$  and  $y$

Then, in order to exterminate  $y$ , let the first equation be multiplied by  $f$ , and the second by  $b$ , and we shall have

$$afx + bfy = cf$$

$$bdx + bfy = bg$$

And by taking the difference of these two equations, there will arise

$$afx - bdx = cf - bg$$

$$\text{Or } (af - bd)x = cf - bg$$

$$\text{And consequently } x = \frac{cf - bg}{af - bd}$$

In like manner, if the first of the two given equations be multiplied by  $d$ , and the second by  $a$ , we shall have

$$adx + bdy = cd$$

$$adx + afy = ag$$

And, the difference of these equations being taken as before, will give

$$bdy - afy = cd - ag$$

$$\text{Or } (bd - af)y = cd - ag$$

$$\text{And consequently } y = \frac{cd - ag}{bd - af}$$

In which case,  $x$  and  $y$  are here found in general terms; and consequently the solution will hold true, whatever numbers may be substituted for  $a, b, c, d, e, f$ , and  $g$ .

If it be required to exterminate three unknown quantities, or to reduce the three simple equations containing them to a single one, it may be done as follows:

Find the value of one of the three unknown quantities in each of the three simple equations containing it; then compare the first of these values with the second, and the second with the third, and there will arise two new equations, containing only two unknown quantities, the values of which may be found by either of the former rules.

Let there be given, for example, the three following equations, to find  $x, y$ , and  $z$ .

$$x + y + z = 53$$

$$x + 2y + 3z = 105$$

$$x + 3y + 4z = 134$$

Then, if  $x$  be exterminated in each of these equations, we shall have,

$$x = 53 - y - z$$

$$x = 105 - 2y - 3z$$

$$x = 134 - 3y - 4z$$

And by comparing the first of these with each of the other two, there will arise the two following equations:

$$53 - y - z = 105 - 2y - 3z$$

$$53 - y - z = 134 - 3y - 4z$$

From which, by transposition, and the rules of addition and subtraction, we shall readily find,

$$y = 52 - 2z$$

$$y = \frac{81 - 3z}{2}$$

And consequently, by equating these two values of  $y$ , we shall obtain,

$$\frac{81 - 3z}{2} = 52 - 2z$$

$$\text{Or } 81 - 3z = 104 - 4z$$

$$\text{Or } 4z - 3z = 104 - 81 = 23$$

Hence  $z = 23$

$$y = 52 - 2z = 52 - 46 = 6$$

$$x = 53 - y - z = 53 - 6 - 23 = 24$$

And if the three following equations be proposed, in general terms,

$$ax + by + cz = d$$

$$a'x + b'y + c'z = d'$$

$$a''x + b''y + c''z = d''$$

Then the values of  $x, y$ , and  $z$ , found in a similar manner, will be as below:

$$z = \frac{ab'd'' - ad'b'' + da'b'' - bad'' + bd'a'' - db'a''}{ab'c'' - ac'b'' + ca'b'' - ba'c'' + bc'a'' - cb'a''}$$

$$y = \frac{ad'e'' - ac'd'' + ca'd'' - da'e'' + dc'a'' - cd'a''}{ab'c'' - ac'b'' + ca'b'' - ba'c'' + bc'a'' - cb'a''}$$

$$x = \frac{db'e'' - dc'b'' + cd'b'' - bd'e'' + bc'd'' - cb'd''}{ab'c'' - ac'b'' + ca'b'' - ba'c'' + bc'a'' - cb'a''}$$

Where, if any numbers whatever be substituted in the place of the literal coefficients, the equation will hold: and in a manner analogous to this, we may exterminate four or more unknown quantities in general terms; and thence, by substitution, determine their values in any numeral equations that may be proposed.

Having thus sufficiently shewn the method of solving simple equations, it will next be proper to proceed to the resolution of quadratic equations, or those of the second power, which, omitting the simple case  $x^2 = a$ , and confining ourselves only to such as are compound, may always be reduced to one of the three following forms:

$$1. x^2 + ax = b$$

$$2. x^2 - ax = b$$

$$3. x^2 - ax = -b$$

Where the value of the unknown quantity  $x$ , in each of the equations, taken according to the order in which they stand, may be exhibited as below:

$$1. x = -\frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}$$

$$2. x = +\frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}$$

$$3. x = +\frac{a}{2} \pm \sqrt{\frac{a^2}{4} - b}$$

Or the general equation  $ax^2 \pm bx = \pm c$ , which comprehends all the three cases above-mentioned, may be resolved by means of the following rule:

Transpose all the terms that involve the unknown quantity to one side of the equation, and the known quantities to the other; observing to arrange them so, that the term which contains the square of the unknown quantity may be positive, and stand first in the equation.

Then, if the square of the unknown quantity have any coefficient prefixed to it, let all the rest of the terms be divided by it, so that the coefficient of the square of the unknown quantity may be 1.

This

# EQUATION.

This being done, add the square of half the coefficient of the unknown quantity itself to both sides of the equation, and the side which involves the unknown quantity will now be a complete square.

Lastly, extract the square root of both sides of the equation, by which means it will be reduced to a simple one; and if the unknown quantity be made to stand alone, on one side of the equation, and the known terms on the other, its value will be determined as was required.

*Note.* The square root of the first side of the equation is always equal to the sum or difference of the unknown quantity, and half the coefficient of the second term, according as that term is + or -.

It may also be observed, that all equations, in which there are two terms involving the unknown quantity, and which have the index of the one just double that of the other, are solved like quadratics, by completing the square.

Thus,  $x^4 - ax^2 = b$ , or  $x^{2n} - ax^n = b$ , are the same as quadratics; their roots being as below.

$$x = \sqrt{\frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}}, \quad x = \sqrt[n]{\frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}}$$

As an illustration of the rule for quadratics given above, the following simple examples in numbers will be found sufficient.

1. Given  $x^2 + 4x = 140$ , to find  $x$ .

Here  $x^2 + 4x + 4 = 140 + 4 = 144$ , by completing the square.

And  $\sqrt{x^2 + 4x + 4} = \sqrt{144}$ , by extracting the root. Or, which is the same thing,  $x + 2 = 12$ .

And consequently  $x = 12 - 2 = 10$ .

2. Given  $x^2 - 6x + 8 = 80$ , to find  $x$ .

Here  $x^2 - 6x = 80 - 8 = 72$ , by transposition.

Then  $x^2 - 6x + 9 = 72 + 9 = 81$ , by completing the square.

And  $x - 3 = \sqrt{81} = 9$ , by extracting the root.

Whence  $x = 9 + 3 = 12$ .

3. Given  $2x^2 + 8x - 20 = 70$ , to find  $x$ .

Here  $2x^2 + 8x = 70 + 20 = 90$ , by transposition.

Then  $x^2 + 4x = 45$ , by dividing by 2.

And  $x^2 + 4x + 4 = 45 + 4 = 49$ , by completing the square.

Whence  $x + 2 = \sqrt{49} = 7$ , by extracting the root.

And consequently  $x = 7 - 2 = 5$ .

4. Given  $\frac{x^2}{2} - \frac{x}{3} + 20\frac{1}{2} = 42\frac{1}{2}$ .

Here  $\frac{x^2}{2} - \frac{x}{3} = 42\frac{1}{2} - 20\frac{1}{2} = 22\frac{1}{6}$ , by transposition.

And  $x^2 - \frac{2}{3}x = 44\frac{1}{3}$ , by dividing by  $\frac{1}{2}$ , or multiplying by 2.

Whence  $x^2 - \frac{2}{3}x + \frac{1}{9} = 44\frac{1}{3} + \frac{1}{9} = 44\frac{4}{9} = 49\frac{0}{9}$ , by completing the square.

And  $x - \frac{1}{3} = \sqrt{49\frac{0}{9}} = \frac{7}{3}$ .

Therefore  $x = \frac{7}{3} + \frac{1}{3} = \frac{8}{3} = 2\frac{2}{3}$ .

It must here, however, be observed, that since the square root of any quantity may be either positive (+) or negative (-), it follows that all quadratic equations will admit of two solutions. Thus, the square root of  $a^2$  (or  $\sqrt{a^2}$ ) is either  $+a$  or  $-a$ ; for  $(+a) \times (+a)$  or  $(-a) \times (-a)$  are each equal to  $a^2$ , by the rules for the signs in multiplication. So, in like manner, if there be given  $x^2 + ax = b$ ,

where  $x + \frac{a}{2}$  is found  $= \sqrt{b + \frac{1}{4}a^2}$ , the root may be +

$\sqrt{b + \frac{1}{4}a^2}$ , or  $-\sqrt{b + \frac{1}{4}a^2}$ , since either of them being multiplied by itself will produce  $b + \frac{1}{4}a^2$ . And this ambiguity is usually expressed by writing the uncertain sign  $\pm$  before  $\sqrt{b + \frac{1}{4}a^2}$ , by which means we have  $x = \pm \sqrt{b + \frac{1}{4}a^2} - \frac{1}{2}a$ ; and the same mode of reasoning is equally applicable to any literal or numeral quadratic equation whatever. Thus, in the first numeral equation above,  $x^2 + 4x = 140$ , it has been found that  $x + 2 = \sqrt{144} = 12$ ; but if the uncertain sign  $\pm$  be put before  $\sqrt{144}$ , it will become  $x + 2 = \pm \sqrt{144} = +12$  or  $-12$ ; and consequently  $x = +12 - 2 = 10$  or  $-12 - 2 = -14$ , which are the two roots of the equation  $x^2 + 4x = 140$ , as will be found by substituting either of them for  $x$ ; the result in both cases being 144.

In addition to this, it may be still farther remarked, that a quadratic equation may be proposed of such a form, or have its coefficients so related to each other, that the value of the unknown quantity can only be exhibited by means of the square root of a negative quantity, which, it is plain, cannot be determined; as there is no quantity, either positive or negative, which being multiplied by itself produces such a form of expression. If, for example, the value of  $x$  were required from the equation  $x^2 + 13 = 4x$ , or  $x^2 - 4x = -13$ , we should find  $x = 2 \pm \sqrt{-9}$ ; and as it is here necessary to extract the square root of  $-9$ , which cannot be determined, the question is shewn to be impossible, or to involve a contradiction.

But although imaginary expressions of this kind are of no other use in the resolution of quadratic equations, than to shew that a particular problem cannot be solved, they must not, on this account, be altogether rejected; as they are well known to be of the greatest use in many mathematical investigations, particularly in some of the higher branches of the science, where no other mode of reasoning could be so successfully or advantageously employed.

Thus, if  $e$  be made to represent the number of which the hyperbolic logarithm is 1, it is well known, as a theorem in trigonometry, that

$$\text{Cos. } x = \frac{e^x \sqrt{-1} + e^{-x} \sqrt{-1}}{2}$$

$$\text{Sin. } x = \frac{e^x \sqrt{-1} - e^{-x} \sqrt{-1}}{2 \sqrt{-1}}$$

Where the sine and cosine of any arc  $x$  is exhibited in a very commodious manner, by means of imaginary exponential expressions; which formulæ, though objected to, and ridiculed by certain writers, are considered, by the celebrated Lagrange (*Leçons, sur des Fonct. Analytiques*) as one of the finest analytical discoveries of the eighteenth century.

Having thus sufficiently explained the nature of quadratic equations, it will be necessary, before we proceed to the resolution of cubics and those of higher dimensions, to shew, how the second term of any equation may be taken away, in order to fit it for a solution; which is done as follows:

Divide the coefficient of the second term of the proposed equation by the exponent of the first term, and add the quotient, with its sign changed, to some new unknown quantity: then if this sum be substituted for the unknown quantity in the proposed equation, a new equation will arise, which will want the second term, as required.

For example, let the quadratic equation  $x^2 - 8x + 15 = c$ , be that of which it is required to take away its second term.

Then since  $\frac{8}{2} = 4$ , if  $x$  be put  $= y + 4$ , we shall have,

$$x^2 =$$

# EQUATION.

$$\begin{aligned} x^2 &= y^2 + 8y + 16 \\ - 8x &= - 8y - 32 \\ + 15 &= + 15 \end{aligned}$$

Whence  $y^2 - 1 = 0$ , the equation required.

From which it appears, that any quadratic equation may be solved without completing the square, by only taking away the second term; for since in the above reduced equation  $y = \sqrt{1} = 1$ , we shall have  $x = y + 4 = 1 + 4 = 5$ .

Again, let the equation  $x^3 - 9x^2 + 26x - 34 = 0$  be given, to exterminate the second term.

Then since  $\frac{9}{3} = 3$ , if  $x$  be put  $= y + 3$ , we shall have,

$$\begin{aligned} x^3 &= y^3 + 9y^2 + 27y + 27 \\ - 9x^2 &= - 9y^2 - 54y - 81 \\ + 26x &= + 26y + 78 \\ - 34 &= - 34 \end{aligned}$$

Whence  $y^3 - y - 10 = 0$ , or  $y^3 - y = 10$ , the equation required.

In like manner, let the following literal equations of the fourth power  $x^4 + px^3 + qx^2 + rx + s = 0$  be given, to exterminate the second term.

Then, by putting  $x = y - \frac{p}{4}$ , we shall have,

$$\begin{aligned} x^4 &= y^4 - py^3 + \frac{3p^2}{8}y^2 - \frac{p^3}{16}y + \frac{p^4}{256} \\ px^3 &= + py^3 - \frac{3p^2}{4}y^2 + \frac{3p^3}{16}y - \frac{p^4}{64} \\ qx^2 &= + qy^2 - \frac{pq}{2}y + \frac{qp^2}{16} \\ rx &= + ry - \frac{rp}{4} \\ s &= + s \end{aligned}$$

Hence  $y^4 + \frac{8q - 3p^2}{8}y^2 + \frac{8r - 4pq + p^2}{8}y + \frac{256s - 64rp + 16qp^2 - 4p^3 + p^4}{256} = 0$ , the reduced

equation required. And the same method of solution may be applied to the taking away the second term of any equation whatever.

Another species of transformation, of use in reducing equations to their simplest form, is that of converting such of the terms as have fractional coefficients into others that shall be integral; which is done by substituting a new unknown quantity, divided by the product of all the denominators, instead of the unknown quantity in the equation; and then, by proper reductions, the equation will be found to have the form required.

Thus, let  $x^4 + \frac{p}{a}x^3 + \frac{q}{b}x^2 + \frac{r}{c}x + \frac{s}{d} = 0$ , be the given equation.

Then, if  $x$  be assumed  $= \frac{y}{abcd}$ , we shall have, by substitution,

$$\frac{y^4}{a^4b^4c^4d^4} + \frac{py^3}{a^3b^4c^4d^4} + \frac{qy^2}{a^2b^4c^4d^4} + \frac{ry}{abc^4d^4} + \frac{s}{d} = 0.$$

And by multiplying the whole equation by  $a^4b^4c^4d^4$  it will become

$$y^4 + bcdy^3 + a^2bcd^2qy^2 + abc^2d^3ry + a^4b^4c^4d^4s = 0,$$

which is of the form required.

This preparation being made, it will now be proper to proceed to the solution of *cubic equations*, or those of which the highest power is of three dimensions; all of which, when expressed in general terms, are of the form

$$x^3 \pm px^2 \pm qx \pm r = 0.$$

Or, if the second term be taken away, by means of the above-mentioned rule, any equation of this kind may be exhibited under the form

$$x^3 \pm px = \pm q$$

And, in this case, the value of the unknown quantity  $x$ , according to the rule usually ascribed to Cardan, is as follows:

$$x = \sqrt[3]{\frac{1}{2}q + \sqrt{(\frac{1}{2}q)^2 + (\frac{1}{3}p)^3}} + \sqrt[3]{\frac{1}{2}q - \sqrt{(\frac{1}{2}q)^2 + (\frac{1}{3}p)^3}}$$

Or  $x = \sqrt[3]{\frac{1}{2}q + \sqrt{(\frac{1}{2}q)^2 + (\frac{1}{3}p)^3}} - \sqrt[3]{\frac{1}{2}q + \sqrt{(\frac{1}{2}q)^2 + (\frac{1}{3}p)^3}}$  the values of  $p$  and  $q$  being always supposed to be taken with the sign  $+$  or  $-$  according as they are found in the given equation.

The rule may be demonstrated thus:

Let the equation, whose root is to be determined, be

$$x^3 + px = q$$

Then if  $x$  be assumed  $= y + z$ , we shall have, by substitution,

$$\begin{aligned} x^3 &= y^3 + 3yz(y+z) + z^3 \\ px &= p(y+z) \end{aligned}$$

Or  $x^3 + px = y^3 + 3yz + p \times y + z + z^3 = q$

And if, in this last equation,  $3yz$  be taken  $= -p$ , we shall have the two following equations for determining the values of  $y$  and  $z$ : *viz.*

$$\begin{aligned} 3yz &= -p \\ y^3 + z^3 &= q \end{aligned}$$

Where, since in the first of them,  $z = -\frac{p}{3y}$ , if this value be substituted in the second, it will become

$$y^3 - \frac{p^3}{27y^3} = q$$

Or by multiplying by  $y^3$ , and then transposing the terms,

$$y^6 - qy^3 = (\frac{1}{3}p)^3$$

And as this equation is now in the form of a quadratic, on account of the index of the highest term being double that of the second, we shall have, by the rule already given for that purpose, and by simple equations.

$$\begin{aligned} y &= \sqrt[3]{\frac{1}{2}q \pm \sqrt{(\frac{1}{2}q)^2 + (\frac{1}{3}p)^3}} \\ z &= \frac{-\frac{1}{3}p}{\sqrt[3]{\frac{1}{2}q \pm \sqrt{(\frac{1}{2}q)^2 + (\frac{1}{3}p)^3}}} \end{aligned}$$

Whence  $x = y + z = \sqrt[3]{\frac{1}{2}q \pm \sqrt{(\frac{1}{2}q)^2 + (\frac{1}{3}p)^3}} - \frac{1}{\sqrt[3]{\frac{1}{2}q \pm \sqrt{(\frac{1}{2}q)^2 + (\frac{1}{3}p)^3}}}$

as was to be shewn.

As a practical application of the rule, let there be given the equation  $x^3 + 6x = 20$ , to find the value of  $x$ .

Thus, if  $p$  be put  $= 6$ , and  $q = 20$ , the analytical expression will become

$$\begin{aligned} \sqrt[3]{10 + \sqrt{100 + 8}} - \frac{2}{\sqrt[3]{10 + \sqrt{100 + 8}}} &= \sqrt[3]{10 + \sqrt{108}} \\ &= \sqrt[3]{10 + 10.3923} - \frac{2}{\sqrt[3]{10 + 10.3923}} \\ &= \sqrt[3]{20.3923} - \frac{2}{\sqrt[3]{20.3923}} \end{aligned}$$

# EQUATION.

$= 2.732 - \frac{2}{2.732} = 2.732 - .732 = 2$ , which is the required value of  $x$ .

It happens, however, that the value of the unknown quantity is here only found by approximation; but this, when the root is a whole number, may always be avoided, for since in the present instance,  $\sqrt[3]{10 + \sqrt{108}} = 1 + \sqrt{3}$ , as may be proved by raising it to the third power, if this be substituted in its proper place, in the above expressions,

$$\begin{aligned} \text{we shall have } \sqrt[3]{10 + \sqrt{108}} - \frac{2}{\sqrt[3]{10 + \sqrt{108}}} &= 1 + \sqrt{3} \\ - \frac{2}{1 + \sqrt{3}} &= \frac{(1 + \sqrt{3})^3 - 2}{1 + \sqrt{3}} = \frac{1 + 2\sqrt{3} + 3 - 2}{1 + \sqrt{3}} \\ &= \frac{2 + 2\sqrt{3}}{1 + \sqrt{3}} = 2, \text{ as before.} \end{aligned}$$

Again, as a second example, let there be given  $x^3 - 6x = -q$ , to find the value of  $x$ .

Here  $p = -6$  and  $q = -q$

Then, by substituting these values in the above formula, we have

$$\begin{aligned} x &= \sqrt[3]{-4\frac{1}{4} + \sqrt{20\frac{1}{2} - 8}} - \frac{-2}{\sqrt[3]{-4\frac{1}{4} + \sqrt{20\frac{1}{2} - 8}}} \\ &= \sqrt[3]{-4\frac{1}{2} + 3\frac{1}{2}} + \frac{2}{\sqrt[3]{-4\frac{1}{2} + 3\frac{1}{2}}} = \sqrt[3]{-1} + \frac{2}{\sqrt[3]{-1}} \\ &= -1 + \frac{2}{-1} = -1 - 2 = -3, \text{ the required value of } x. \end{aligned}$$

But as a quadratic equation has been shewn to have two roots, or values, of the unknown quantity, so, in like manner, it may be proved that the unknown quantity, in a cubic equation, has three values or roots, each of which will be found to answer the conditions of the question.

Thus, in the first equation  $x^3 + 6x - 20 = 0$ , given above, where  $x$  has been found = 2, or  $x - 2 = 0$ , if  $x^3 + 6x - 20 = 0$  be divided by  $x - 2$ , we shall have  $x^2 + 2x + 10 = 0$ , or  $x^2 + 2x = -10$ , the roots of which equation, found according to the rule for quadratics, are  $-1 + 3\sqrt{-1}$ , and  $-1 - 3\sqrt{-1}$ , each of which, as well as the former root 2, are values of the unknown quantity, as will be found by substituting them for  $x$  in the given equation.

It must be observed, however, that neither the formula of Cardan, nor any other that has yet been discovered, will be found sufficient to determine the numerical value of the unknown quantity in every cubic equation that can be proposed; for when the coefficient of the second term of the equation is negative, and the cube of  $\frac{1}{3}$  of it is greater than the square of half the absolute term, the expression for the root becomes imaginary; and therefore no intelligible result can be derived from it.

Thus, if the equation proposed, were  $x^3 - 3x = 1$ , the analytical expression, when converted into numbers, will become  $x = \sqrt[3]{\frac{1}{2} + \sqrt{\frac{1}{4} - 1}} - \frac{1}{\sqrt[3]{\frac{1}{2} + \sqrt{\frac{1}{4} - 1}}}$

$\sqrt[3]{\frac{1}{2} + \frac{1}{2}\sqrt{-3}} - \frac{1}{\sqrt[3]{\frac{1}{2} - \frac{1}{2}\sqrt{-3}}}$ , the value of which cannot be determined either in integers, fractions, or rational surds; although, by substituting it for  $x$  in the given equation, the terms will all vanish as they ought; and consequently, in a certain sense, it may be said to be a root of the equation.

This defective state of Cardan's formula, or that in which it fails as a general rule, has commonly been called

the *irreducible case of cubic equations*; and notwithstanding the reiterated efforts of the most celebrated analysts in Europe, from the time when the want of generality in the rule was first observed, to the present day, no remedy has been found for this defect, except by a method of solution which is derived from the trisection of an angle, or by converting the expression into an infinite series; in which latter case that part of the quantity which is imaginary disappears, and by that means enables us to compute the root to any degree of exactness. For it is to be remarked, that although the unknown quantity cannot be determined from the formula itself, yet all the three roots are, in this case, real, and can be found, at least approximately, by either of the two methods last-mentioned.

Leaving this part of the subject, for the present, we shall next proceed to *biquadratic equations*, or those of the fourth power; any one of which, when the second term is taken away, may be represented, in general terms, by  $x^4 + ax^2 + bx + c = 0$ ; and the rule for the resolution of any equation of this form, is as follows:

Find the value of  $y$  in the cubic equation  $y^3 - \frac{a^2 + 12c}{3}y = b^2 + \frac{2a}{27}(a^2 - 36c)$ , by the rule before given for this purpose; and let the root, thus determined, be denoted by  $v$ .

Then find each of the values of  $x$  in the two following quadratic equations,

$$\begin{aligned} x^2 + (\sqrt{v - \frac{2}{3}a})x &= -\left[\frac{1}{2}a + \frac{1}{2}(v - \frac{2}{3}a)\right] + \frac{b}{2\sqrt{v - \frac{2}{3}a}} \\ x^2 - (\sqrt{v - \frac{2}{3}a})x &= -\left[\frac{1}{2}a + \frac{1}{2}(v - \frac{2}{3}a)\right] - \frac{b}{2\sqrt{v - \frac{2}{3}a}} \end{aligned}$$

And the values of  $x$ , thus found, will be the four roots of the biquadratic equation  $x^4 + ax^2 + bx + c = 0$ , as was required.

The rule, which is here given in a more commodious form than that of Des Cartes, may be readily demonstrated, by making the given equation  $x^4 + ax^2 + bx + c = 0$ , equal to the product of two quadratic equations, and then equating the coefficients of the homologous terms. Thus, if  $x^2 + px + q$  be multiplied by  $x^2 - px + r$ , and the product thence arising put = 0, we shall have  $x^4 + (r + q - p^2)x^2 + p(r - q)x + rq = 0$ .

Hence  $r + q - p^2 = a$ ,  $p(r - q) = b$ , and  $rq = c$ ; and consequently  $2r = a + p^2 + \frac{b}{p}$ , and  $2q = a + p^2 - \frac{b}{p}$ .

And if these values be substituted in the equation  $rq = c$ , or its equal  $4rq = 4c$ , we shall obtain, after proper reduction, the equation  $p^6 + 2ap^3 + (a^2 - 4c)p^2 = b^2$ .

Or, by putting  $p^2 = y - \frac{2}{3}a$ , and substituting it in the latter equation, we shall have for the result the cubic equation  $y^3 - \frac{a^2 + 12c}{3}y = b^2 + \frac{2a}{27}(a^2 - 36c)$ , which is that given in the rule.

Hence, if the value, or root of  $y$ , in this equation, be put =  $v$ , we shall have, from the equations given above,  $p = \sqrt{v - \frac{2}{3}a}$ ,  $q = \frac{1}{2}a + \frac{1}{2}(v - \frac{2}{3}a) - \frac{b}{2\sqrt{v - \frac{2}{3}a}}$ , and  $r = \frac{1}{2}a + \frac{1}{2}(v - \frac{2}{3}a) + \frac{b}{2\sqrt{v - \frac{2}{3}a}}$ . And by substituting

# EQUATION.

Substituting these values in the two quadratic equations  $x^2 + px + q = 0$ , and  $x^2 - px + r = 0$ , they will become  $x^2 + (\sqrt{v - \frac{2}{3}a})x = -\frac{1}{2}a - \frac{1}{2}(v - \frac{2}{3}a)$

$$+ \frac{b}{2\sqrt{v - \frac{2}{3}a}}, \text{ and } x^2 - (\sqrt{v - \frac{2}{3}a})x = -\frac{1}{2}a - \frac{1}{2}(v - \frac{2}{3}a) - \frac{b}{2\sqrt{v - \frac{2}{3}a}}$$

the roots of which equations will be the 4 roots of the proposed biquadratic equation  $x^4 + ax^2 + bx + c = 0$ . As a practical example for the exercise of this rule, let there be given  $x^4 - 6x^2 - 16x + 21 = 0$ , to find the 4 values of  $x$ .

Then, if the numbers  $-6$ ,  $-16$ , and  $21$  be substituted in the place of  $a$ ,  $b$ ,  $c$ , in the cubic equation  $y^3 - \frac{a^2 + 12c}{3}y = b^2 + \frac{2a}{27}(a^2 - 36c)$ , it will become  $y^3 - \frac{36 + 252}{3}y = 256 - \frac{12}{27}(36 - 756)$ , or  $y^3 - 96y = 576$ , where the value of  $y$ , as determined by the preceding rule for cubic equations, will be found  $= 12$ .

Hence, if  $12$  be put for  $v$ ,  $-6$  for  $a$ , and  $-16$  for  $b$ , in the two quadratic equations,

$$x^2 + (\sqrt{v - \frac{2}{3}a})x = -\frac{1}{2}a - \frac{1}{2}(v - \frac{2}{3}a) + \frac{b}{2\sqrt{v - \frac{2}{3}a}}$$

$$x^2 - (\sqrt{v - \frac{2}{3}a})x = -\frac{1}{2}a - \frac{1}{2}(v - \frac{2}{3}a) - \frac{b}{2\sqrt{v - \frac{2}{3}a}}$$

they will become,

$$x^2 + (\sqrt{12 + 4})x = 3 - 8 - 2 = -7$$

$$x^2 - (\sqrt{12 + 4})x = 3 - 8 + 2 = -3$$

Or,

$$x^2 + 4x + 7 = 0$$

$$x^2 - 4x + 3 = 0$$

In the first of which  $x = -2 + \sqrt{-3}$ , or,  $-2 - \sqrt{-3}$ . And in the second,  $x = 3$  or  $1$ , which are the roots of the given equation  $x^4 - 6x^2 - 16x + 21 = 0$ ; there being always as many values of the unknown quantity, in any equation, as there are units in the index of its highest power; as will be shewn in a succeeding part of this article.

But before we proceed to any enquiries of this kind it will be proper to observe, that no general rule has hitherto been found for resolving equations of the 5th, 6th, or other higher orders, notwithstanding the numerous attempts that have been made for this purpose; so that in this respect we have not been able to advance a single step beyond what had been done by Louis Ferrari, Bombelli, and others in the early part of the 17th century, who were all acquainted with the method of resolving biquadratic equations; which is still the boundary that the most skilful analysts, assisted by all the advantages of a more comprehensive and commodious calculus, have not been able to pass.

But although no general resolution has hitherto been given of equations higher than those of the 4th power, there are, notwithstanding, some particular equations, of all orders, which, on account of certain relations subsisting between the coefficients of their different terms, may be resolved by the rules which have been given for those of the first four orders.

This is particularly the case with what have been usually called *reciprocal equations*, which are such that the coefficients of the terms form the same numerical series, whether taken in a direct or an inverted order; or that remain the

same when the reciprocal of the unknown quantity, or  $\frac{1}{x}$  is substituted for  $x$ .

Thus, for example, the equations  $x^5 + px^4 + qx^3 + qx^2 + px + 1 = 0$ ,  $x^4 + px^3 + qx^2 + px + 1 = 0$ , &c. which are of this kind, may always be transformed into others of a degree denoted by half the exponent of the highest power of the unknown quantity, if it be an even number, or by half the exponent diminished by 1, if it be an odd number.

Thus, let the last of the two equations given above,  $x^4 + px^3 + qx^2 + px + 1 = 0$ , be taken in the form  $x^2 + \frac{1}{x^2} + p(x + \frac{1}{x}) + q = 0$ , to which it can be readily reduced; then if  $x + \frac{1}{x}$  be put  $= z$ , we shall have  $x^2 + z + \frac{1}{x^2} = z^2$ , or  $x^2 + \frac{1}{x^2} = z^2 - z$ ; and if this be substituted

in the original equation  $x^4 + px^3 + qx^2 + px + 1 = 0$ , it will become  $z^2 + pz = z - q$ . And since  $x + \frac{1}{x} = z$ ,

we shall have  $x^2 - zx + 1 = 0$ . Hence, if the two roots of the equation  $z^2 + pz = z - q$ , be denoted by  $r$  and  $r'$ , we shall have the two following equations  $x^2 - rx + 1 = 0$ , and  $x^2 - r'x + 1 = 0$ ; the roots of which will be the four roots of the given biquadratic equation  $x^4 + px^3 + qx^2 + px + 1 = 0$ .

And in a similar way may any other equation of this kind be resolved, when the index of the greatest power of the unknown quantity is an even number.

And if the index of the unknown quantity be an odd number, as in the equation  $x^5 + px^4 + qx^3 + qx^2 + px + 1 = 0$ , it is obvious from inspection only, that  $-1$  is a root of the equation; and, consequently, if  $x^5 + px^4 + qx^3 + qx^2 + px + 1 = 0$ , be divided by  $x + 1$ , it will be reduced to the form  $x^4 + (p-1)x^3 - (p-q-1)x^2 + (p-1)x + 1 = 0$ , which is another reciprocal equation, a degree lower than the former; and having the index of its highest power an even number, it is consequently resolvable in the manner above explained.

Also, when two or more roots of any equation are equal to each other, the equation may always be reduced to another of an inferior degree, and the roots, by that means, determined.

Thus, if the cubic equation  $x^3 - px^2 + qx - r = 0$ , has two equal roots, each of them will be  $x = \frac{pq - qr}{p^2 - 6q}$ .

For, let the three roots be denoted by  $a, a$  and  $b$ ; then by the composition of equations we shall have  $x^3 - (2a + b)x^2 + (a^2 + 2ab)x - a^2b = 0$ ; where  $2a + b = p$ ,  $a^2 + 2ab = q$ , and  $a^2b = r$ ; and if these values be substituted in the above form, it will become  $x = \frac{pq - qr}{p^2 - 6q} = \frac{2a^3 + 4a^2b + a^2b + 2ab^2 - 9a^2b}{8a^3 + 8ab + 2b^2 - 6a^2 - 12ab} = \frac{2a^3 - 4a^2b + 2ab^2}{2a^2 - 4ab + 2b^2} = a$ , as was to be shewn.

Thus, let the equation  $x^3 + 5x^2 - 32x + 36 = 0$ , which has two equal roots, be the one proposed to be resolved.

Then since  $p = -5$ ,  $q = -32$ , and  $r = -36$ , if these values be substituted in the formula  $x = \frac{pq - qr}{p^2 - 6q}$ , it will become  $x = \frac{-5 \times -32 - 9 \times -36}{2 \times 25 - 6 \times -32} = \frac{160 + 324}{50 + 192} = \frac{484}{242} = 2$ , which is one of the equal roots of the equation.

# EQUATION.

sum of the products of all the roots, multiplied together, two by two.

3. The coefficient of the fourth term, taken with a contrary sign, is equal to the sum of the products, of all the roots, multiplied together, three by three; and so on to the last term, which is equal to the product of all the roots with contrary signs.

From this it also follows, that in an equation wanting its second term, there must be both positive and negative roots, and that the sum of the former is equal to that of the latter.

And in the same way, a number of other properties of the various orders of equations may be derived, which will be found of great use, not only with respect to their resolution, but as furnishing the materials for a complete investigation of this curious and interesting branch of analysis.

We shall only farther add, that besides the simple factors into which any equation may be decomposed, it may likewise be produced by multiplying together factors of any degree, provided the sum of their dimensions be equal to that of the proposed equation.

For the application of the principles and rules, illustrated in the preceding article, to the solution of arithmetical, geometrical, and other questions and problems, we refer to *REDUCTION of Equations, APPLICATION of Algebra, &c.*

**EQUATION**, in *Astronomy*, is a term used to express the correction, or quantity, to be added to or subtracted from the mean position of a heavenly body, to obtain the true; it also, in a more general sense, implies the correction arising from any erroneous supposition whatever. *E.g.* The time of noon, determined by taking equal altitudes of the sun, is first obtained by supposing the sun's declination constant during the whole interval, which false supposition is corrected by an appropriate equation. Most of the principal equations will be found under their different articles, in the various tables to which they belong.

**EQUATIONS, Construction of.** See **CONSTRUCTION of Equations.**

**EQUATIONS, Conversion of.** See **CONVERSION of Equations.**

**EQUATIONS, Absolute, adjoined or affected, differential, eminential, exponential, fluxional, literal, numeral, and transcendental.** See the adjectives.

**EQUATION of a Curve**, is an equation shewing the nature of a curve, by expressing the relation between any absciss and its corresponding ordinate, or else the relation of their fluxions, &c. Thus, the equation for the circle is  $ax - x^2 = y^2$ , where  $a$  is its diameter,  $x$  any absciss or part of that diameter, and  $y$  the ordinate at that part of the diameter; and the equation denotes, that whatever be the absciss expressed by  $x$ , the square of its corresponding ordinate will be  $ax - x^2$ . Thus also the equation for the ellipse is  $\frac{p}{a} \times ax - x^2 = y^2$ ; for the hyperbola  $\frac{p}{a} \times ax + x^2 = y^2$ ; and for the parabola  $px = y^2$ ; in all which  $a$  is an axis, and  $p$  the parameter. This method of expressing the nature of curves by algebraical equations was first introduced by Des Cartes, who, by thus connecting together the two sciences of algebra and geometry, made them naturally subservient and auxiliary to each other, and thus laid the foundation of the most considerable improvements that have been made in every branch of them since that time. See **APPLICATION of Algebra, &c.** See also **CURVE.**

**EQUATION of Payments**, in *Arithmetic*, is the method of reducing several debts payable at different times, and bearing

no interest till after the term of payment of a single debt or payment, to be discharged at once, without loss either to debtor or creditor, allowing simple interest; or, it is the method of finding the equated term at which these several debts should be paid in one sum. Cocker, Hatton, Kersey, fir Samuel Moreland, and Ward, have given rules for this purpose, which Mr. Malcolm has examined and found to be erroneous; and though the error resulting from any of the rules which they have proposed is not very considerable, the following process furnishes one more accurate.

Let the debt first payable be  $d$  | The last payable debt  $D$   
 called  $d$   
 The distance of the term of payment  $t$  | The distance of the term  $T$   
 The distance of the equated time  $x$

The rate of interest, or 1 year's interest of 1*l.*  $r$   
 The distance of the time  $t$  and  $x$  is  $x-t$  } for  $x$  lies between them.  
 The distance of the time  $T$  and  $x$  is  $T-x$  }

Then the interest of  $d$  for the time  $x-t$  is  $dr \times x-t$ , or  $drx - drt$ ,  $dr$  being one year's interest of  $d$ ; and  $\frac{DT r - Dr x}{1 + T r - r x}$  is the discount of  $D$  for the time  $T-x$ ,

because  $T r - r x$  is the interest of 1*l.* for that time, which is consequently the discount of  $1 + T r - r x$  for the same time; consequently, from the nature of the question, we shall have  $drx - drt = \frac{DT r - Dr x}{1 + T r - r x}$ ; which

being reduced, gives  $T + t + \frac{D + d}{dr} \times x - x^2 =$

$\frac{DT + dt}{dr} + Tt$ . Then make  $T + t + \frac{D + d}{dr} = a$ , and

$\frac{DT + dt}{dr} + Tt = s$ , and  $ax - x^2 = s$ ; and resolving this

quadratic equation,  $x = \frac{a}{2} \pm \sqrt{\frac{a^2}{4} - s}$ .

*E.g.* Suppose 100*l.* payable one year hence, and 105*l.* payable three years hence; what is the equated time, allowing simple interest at 5 per cent. per annum?

Here  $d = 100$  {  $D = 105$  }  
 $t = 1$  {  $T = 3$  }  $r = .05$ .

Then  $D + d = 205$ ,  $dr = 5$ , and  $\frac{D + d}{dr} = \frac{205}{5} = 41$ .

And  $T + t + \frac{D + d}{dr}$ , or  $a = 4 + 41 = 45$ .

And  $s$  or  $\frac{DT + dt}{dr} + Tt = \frac{315 + 100}{5} + 3 = 83 + 3 = 86$ . Consequently,

$x = \frac{45}{2} \pm \sqrt{\frac{2025}{4} - 86} = \frac{45}{2} \pm \sqrt{506.25 - 86} = 22.5$

$\pm \sqrt{420.25} = 22.5 \pm 20.5 = 43$  or  $2$ : but  $43$  cannot be the true answer by the conditions of the question, since it is greater than the distance of the last term in the question; and therefore  $2$  is the answer required.

If there are more debts than two you must first find an equated time for the two that are first payable; then consider their sum as a debt payable at that equated time, and find another equated time for that debt and the next of the given debts, &c. See Malcolm's *Arithm.* book vi. § 5, or p. 616-621.

**EQUATION of the Centre.** This is the first and most considerable of all the equations that are applied to the mean motion of a planet. It arises immediately from the nature of the ellipse. If the orbit of a planet was perfectly circular

## EQUATION.

circular it would have no equation of the centre; and a spherical body, revolving round a centre of force in an elliptic orbit, undisturbed by the motion of other bodies, would require no other equation to correct its mean motion than the equation of the centre.

The necessity of applying this equation to the motion of the sun, in its apparent orbit, was known to the early astronomers; for, in fact, no very accurate observations were necessary to shew that the sun did not perform equal parts of its annual motion in equal portions of time. When, by means of gnomons, the length of the year and the obliquity of the ecliptic were pretty well established, it must have been easy, with the same instrument, to have observed the declination of the sun every day, and from thence to have computed its longitude. The first astronomers who undertook this examination must naturally have expected to find a regular increase in the sun's longitude for every day in the year; but when they found that in the course of three months the observed longitude differed near two degrees from that which they had computed, it became then evident, that if the sun's orbit was circular, and its motion uniform, at least the earth was not placed in the centre of it.

This difference, which we now call the equation of the centre, was named by the ancient astronomers *προσφαιρισις*, from *προσθεσις*, addition, and *αφαιρισις*, subtraction, because this equation is sometimes additive and sometimes subtractive, a name almost applicable to all equations, but applied to the equation of the orbit as the most considerable of all. Hipparchus was acquainted with this inequality in the motion of the sun, which had not long been discovered before his time. He observed, that from the equinox of spring to the summer solstice, there was an interval of  $94\frac{1}{2}$  days, and from the solstice to the next equinox  $92\frac{1}{2}$  days; that is, two days less, notwithstanding these points were equally  $90^\circ$  from each other. The motion of the sun in two days is  $1^\circ 58'$ , which is nearly the quantity of the greatest equation. To explain this difference, and to assign the exact proportion to every day in the year, the ancient astronomers either placed the earth out of the centre, at a sufficient distance to produce the greatest equation, or imagined an epicycle to revolve upon the circular orbit, on whose circumference the sun was supposed to move. These suppositions would give the sun's longitude near enough the truth to satisfy the imperfect observations of those days, and when similar inequalities were observed in the moon and planets, new cycles and epicycles were invented to explain them. But these contrivances, however ingenious, had very little pretension to be classed as theories or hypotheses, capable of giving a satisfactory explanation of the causes of these phenomena. An ingenious mechanic may make a clock, that shall represent all the inequalities of solar time, and by a proper application of some very simple principles in practical mechanics, we may represent the most complicated system of motions; yet these machines would give us no instructions as to the original motions which they imitated; and in proportion as they became complicated, should we be the less inclined to suppose any resemblance between their mechanism, and that of the motions they represented.

Nevertheless, in the simple case that we are now considering, had observation accurately agreed with the supposition, there would have been no reason for not admitting it; it would have rested on the same ground as Kepler's elliptic hypothesis, before Newton had demonstrated how obviously it is derived from one general law of nature.

• For the method of calculating the greatest equation of

excentric orbits, we refer the reader to De la Lande's *Astronomy*, vol. ii.

We shall here only explain the nature of this equation in an orbit perfectly elliptical. The equation of the orbit of a planet is evidently nothing at the apsidal; beginning to reckon from the aphelion it augments rapidly; as the true or real motion being there the slowest, differs most from the mean motion, it continues to increase, but less and less rapidly, till the planet has arrived at some point about three signs, and something more from the aphelion, at which point the true and mean motions are equal. At this time the equation is the greatest, it begins then slowly to diminish, and the diminution becomes more and more rapid, as it approaches the perihelion, at which time the real motion exceeds the mean motion by the greatest quantity. When it arrives at the aphelion the equation is again nothing. In the same manner it increases again to a maximum, and then diminishes till its return to the aphelion, where it is again nothing. The equation is subtractive in the first six signs from the mean motion, and additive in the others.

The greatest equation may be derived directly from observation; or if the excentricity be known it may be computed, and at the same time the degree of anomaly in which it happens. For this purpose it is sufficient to find the point M (*Plate XII. Astronomy, fig. 107.*) where the planet is at its mean distance. For it is evident, that the moment the planet arrives at the point where its angular velocity D F M is equal to its mean velocity, the mean longitude will cease to gain upon the true longitude, but their difference will be a maximum; because till that moment the real velocity, which was least, had continually caused the mean velocity to accelerate upon the true, but from the moment they are equal, the real velocity begins to accelerate upon the mean, and to regain the quantity which it had before lost: from this time the true and mean place approach each other, and the equation begins to diminish. Thus the problem consists in finding the point M, and the true anomaly A F M of the planet, at the moment that its true velocity is equal to the mean angular velocity.

Take FM a mean proportional between the two semi-axes of the orbit. With the focus F as a centre, and distance FM, describe a circle MN, which circle will have a surface equal to the ellipse. Suppose a body to describe uniformly this circle in the same time in which the planet describes its ellipse, its angular velocity will always be equal to the mean angular velocity of the planet in the ellipse; and the area described in the circle will be always equal to the area described in the ellipse, because the planet always describes equal areas in equal times. For example, if the planet describes in one day an area D F R =  $\frac{1}{353}$ th part of the elliptic surface, the area E F O, described in the circle, will likewise be the  $\frac{1}{353}$ th part of the area of the circle; and the real velocity of the planet, or the angle D F R, will be equal to the mean velocity in M, that is, to the angle E F O; for there are two equal sectors having the same length E M, the same surface, and consequently the same angle. Besides the equal triangles M E D, M R O, which are the one without, and the other within the circle, shew that the elliptic sector is precisely equal to the circular sector, that has the same angle in F. Therefore to find the point of the mean velocity, we must find at what degree the intersection of the ellipse corresponds with the circle equal to it in surface. From the point M let the straight line M B be drawn to the other focus of the ellipse, then in the triangle B E M three sides will be known; namely, B F, which is the double of the excentricity, F M, which is the mean proportional between the two semi-axes, and B M, which is the difference between

## EQUATION.

FM, and the greater axis, because the two lines EM and MB are together equal to the greater axis. By resolving this triangle the angle F may be found, which will be the true anomaly of the planet, at the time of its greatest equation.

In the case of the greatest equation, the resolution of the above triangle gives the following rule. From the aphelion distance take separately the mean proportional of the two semi-axes, and the third side BM (difference between the greater axis and the mean). Take the logarithms of these differences, and subtract the least from the greatest; from this difference take the difference of the logarithms of the aphelion and perihelion distances; the half of the remainder is the logarithmic tangent of half the true anomaly. By the method of cosines take the logarithms of the aphelion distance, and of the difference of the side BM; add the complements of the logarithms of BE and FM, the half of the sum is the logarithmic cosine of half the true anomaly. If the angle is small, this method of the cosines is less exact; but when the angle is large, it is preferable to the other, being somewhat shorter.

Having thus described the method of calculating the greatest equation, we have now to consider the manner of observing it.

From the instant a planet departs from its aphelion A, to the time it arrives at the point M of its greatest equation, its real velocity is less than its mean velocity; therefore, the true anomaly is less than the mean anomaly, and differs from it more and more. When the planet has passed the point P, or its perihelion, and arrives at the point G, having about nine signs of anomaly, its true distance AFG from the aphelion is in the same manner less than its mean distance, by a quantity equal to the greatest equation. If we observe two true longitudes of the planet in G and M, they will differ from each other by the angle GFM, which is the sum of two true anomalies: but the sum of two mean anomalies will be greater by the double of the equation, since each true distance is less than the mean distance by the whole of the equation. It is easy to calculate the sum of two mean anomalies without knowing the place of the aphelion A, because the sum of two mean anomalies is equal to the mean motion of the planet for this interval of time, which is found by taking its proportion of the whole revolution: thus, the excess of the mean motion, calculated over the true distance observed, will be double the greatest equation, provided the two observations are made in M and G, the times that the mean velocities equal the true. It will, on the contrary, be the true or observed motion that will exceed the mean, if the observations are taken on each side the perihelion. To determine the time and the observations most suitable to this investigation, an observer, who should be supposed to have no previous knowledge of the situation of the orbit, must begin by collecting a great number of observed positions, and compare them two and two together, and observe how much the observed motion differs from the mean for each interval: in this manner the greatest of the observed distances will be found double the greatest equation; but if this comparison is made with a single observation, then the greatest difference additive and the greatest subtractive, added together, will give double the equation. But since at present we know very nearly the place of the apsidæ, and of the mean distances of all the planets, we can immediately select the observations that are made about the time of the greatest equation.

*Example.*—The 7th October, 1751, the place of the

sun observed by La Caille, was, after three successive observations

6	13°	47'	13".7
0	8	9	25.5

5	24	22	11.8
5	20	31	43.2

0	3	50	28.6
0	1	55	14.3

This would be exactly the greatest equation, if the observations had been made exactly at the moment of the greatest equation; but having calculated by the tables these equations, it was found that 18".6 must be added to have the greatest equation, which will make the above quantity 1° 55' 33".

With respect to this 18".6 it may be remarked, that an error of several minutes in the equation of the tables would have produced no sensible alteration in this correction, as the error would be the same for the given day as for the greatest of all which happened extremely near it.

As it is extremely rare to meet with two observations which are precisely situated in the two points M and G of the mean time, so it is not easy to find by the first calculation the exact value of the equation; but after having found it very nearly, and likewise the place of the apside, the equation may be calculated for the times of observation, and likewise the greatest equation; by the method explained above, it may be then seen how much the equation derived from the observations should differ from the greatest. It was by this means that La Caille, in the preceding example, found the above correction 18".6. The greatest equation of the sun is that which may be observed the most frequently, and with the greatest ease. A person studying astronomy, and desirous of making himself conversant with the methods by which all these elements of the planetary motions have been obtained, may deduce them himself from the Nautical Almanac, or other similar publications; he may regard the longitudes and latitudes of the planets there found as so many observations, and by computing from them, the original elements should be found, from which the tables themselves were calculated. If the minutes and seconds be omitted, or the nearest half or quarter of a degree only taken, they will represent the observations of the early astronomers, and it will then be seen what very imperfect theories were sufficient to explain such inaccurate observations.

These methods of finding the greatest equation cannot be applied to Mercury, as we never can observe its heliocentric longitude but when on the sun's disc. Its elongation, and that of Venus, is found by observing the greatest digression when the planet is in the apsidæ. For a farther account of this method consult De la Lande's Astronomy.

Cassini employed the transits of Mercury observed in 1661, 1690, and 1697, and found the greatest equation 24' 3". De la Lande, from the transits of 1740, 1743, and 1753, found 23° 27' 51". But these observations are not well suited, as the three points of the orbit are not disposed at distances sufficiently great. The equation of the centre does not remain for ever the same; by comparison with ancient observations the equation of the earth's orbit appears to have undergone a diminution, and the theory of attraction explains the cause, and assigned the quantity more correctly than can be obtained by observation. La Place makes the diminution for the earth's orbit 0°.0058 decimals in a century;

## EQUATION.

lary; this phenomenon supposes a corresponding diminution in the excentricity, for if the excentricity was nothing, the equation would be nothing. The corresponding diminution of the excentricity is 0.000045553, the semi-axis major being taken as unity.

This is nearly equal to 1548 French leagues in a century, or 40 English miles in a year. Thus, fractions which appear insensible in the heavens, become considerable when compared with our known measures. If this diminution was always progressive, the solar ellipse would in time be changed into the circumference of a circle, and in the end, the ex-

centricity decreasing always, the earth, after a great number of ages, would fall into the sun; but the theory of attraction indicates that the variation in the equation of the orbit and excentricity are periodic, and that after having diminished for a certain period, they will again increase and take the same values they had before, and will thus oscillate within narrow limits; but the periods of these oscillations are still unknown, and thus the system might be eternally maintained, except some exterior and unknown cause shall come to change the system of the world, and new-modify its laws.

TABLE of the greatest Equation of the Centre according to different Astronomers.

	Bouillaud, 1645.	La Hire, 1702.	Halley, 1719.	Cassini, 1740.	La Lande, 1750.	Annual Variation.
Mercury - - -	24° 17' 20"	24° 16' 52"	23° 42' 36"	24° 2' 58"	23° 40' 0"	+ 0".02

*EQUATION, Secular, of the Mean Motion of the Moon.* The motion of the moon, and its elements, do not remain constant, but undergo progressive alterations, which would soon render the tables inaccurate, if we were obliged to improve merely by comparison with recent observations. The only method of avoiding this inconvenience is to calculate the elements of the lunar motion for different periods very remote from each other, to deduce the variations they have undergone, and then to investigate the laws proper to represent them.

We may apply these considerations to the mean and secular motion of the moon, which has been determined with great exactness by modern observations, and which serves as a basis for all the other results, and compare it with ancient observations, to see if it is the same, or if it has materially changed. The method of making this comparison consists in considering the ancient observations of the moon as so many observed longitudes; the place of the moon is then calculated by the tables for this distant epoch, and the result compared with the observation.

The most ancient eclipse upon record may be taken as an example. It was observed by the Chaldeans 721 years before the Christian era, and recorded by Ptolemy. The observation was made at Babylon the 19th March: the moon began to be eclipsed about an hour after its rising. At the middle of the eclipse the longitude of the moon was equal to that of the sun; this latter is easy to calculate by the solar tables; thus the longitude of the moon is given at the period of the eclipse. Now, if the place of the moon be calculated by the tables for this epoch, it will be found less advanced in its orbit, than it must have been by the observation: the difference is about one degree and a half; and as this is too great an error to be attributed to the inaccuracy of the tables, we must conclude that the motion of the moon is now accelerated: so that in referring it to a distant period, we throw it too far back in its orbit, which diminishes its longitude.

And this result acquires additional confirmation, by making similar comparisons with observations made at in-

termediate periods; for if the motion of the moon is really accelerated, we should still find the longitude calculated by the tables too small, though the error should be less as the interval is smaller; and this appears to be the case by a similar comparison with an eclipse observed at Cairo by Ibn-junis, an Arabian astronomer of the 10th century.

This coincidence leaves no doubt as to the reality of the phenomenon; and it appears certain, that the motion of the moon has accelerated from the time of the Chaldeans to the Arabians, and from that time to the present. To represent this acceleration, a third term, proportional to the time, must be added to the secular motion of the moon, and another lesser term proportional to the cube; this, together, is what is called the secular equation of the moon. According to La Place, (*Mecanique celeste*, vol. iii. p. 273.) if  $n$  be the number of centuries elapsed since 1750, the formula for the correction will be  $31''.424757 n^2 + 0''.05721742 n^3$ . These seconds are according to the decimal division.

But we are not to infer that this acceleration will always be increasing, or that the preceding formula will always represent it; the theory of attraction, in making known the cause, has shewn that it is periodic, and connected with the variations of the excentricity of the terrestrial orbit. See *EXCENTRICITY, and EQUATION of the Centre.*

This acceleration, after increasing to a certain limit, will be changed into a retardation, but the extent of this period is very considerable; and the interval, which separates us from the most ancient observations, has yet only developed an extremely small part of this revolution. The inequalities which will result in the motion of the moon will amount at least to a 40th part of the circumference of her orbit. Posterity, who will observe these great phenomena, may remark, and not without gratitude, that the geometers of the present age have foreseen, calculated, and prepared for their successors the means of judging of the past and future state of the system of the world, with the same certainty as in the age in which they lived.

It was the celebrated Dr. Halley who first discovered the effects of this acceleration; and La Place, by a most profound

## EQUATION.

found analysis, has explained both the cause and the law. The observer and the geometrician are each entitled to admiration. If the result of the latter is more satisfactory and useful to science, it must be confessed, that it was a proof of no small sagacity in the former to be the first to doubt of the uniformity of the mean motions which had been admitted as an established principle for above two thousand years.

**EQUATIONS, Secular, which affect the Elements of the Orbit of the Moon.** The motion of the lunar perigee is not uniform, but subject to a secular equation analogous to that of the mean motion, and depending on the same cause. The comparison of ancient observations with the modern leaves no doubt of this fact; but it is to the theory of attraction that we are indebted for the discovery. This equation is equal to that of the mean motion, multiplied by the coefficient  $-3.00052$ , that is to say, that if  $k$  represent the secular equation of the mean motion, the term  $-3.00052k$  must be added to the mean longitude of the perigee, calculated from the duration of a tropical revolution. *Mec. celeste*, vol. iii. p. 247.

The motion of the nodes is likewise subject to a similar inequality, and the equation has the same sign as that of the perigee, it is equal to the equation of the mean motion multiplied by  $-0.735452$ , that is, to the mean longitude of the node add  $-0.735452k$ . These results are confirmed by observation.

It appears from this, that the secular equation diminishes the longitude of the perigee and of the nodes when it augments the mean motion of the node, and reciprocally; hence the motion of the perigee and of the nodes becomes slower, when that of the moon is accelerated, and on the contrary is accelerated when that of the moon is retarded. Moreover, these inequalities are connected together by very simple analogies, since they are represented by the numbers  $1$ ;  $3.00052$ ;  $-0.735452$ .

The anomalistic revolution, depending at the same time on the motion of the moon and of the perigee, is likewise modified by the secular variation. It is the same with all the quantities which depend on the apogee, and on the nodes.

The theory of attraction indicates, that the distance of the moon from the earth, the excentricity, and the inclination to the orbit, are equally subject to secular equations, which are connected with that of the mean motion. But hitherto their effect is scarcely perceptible; nevertheless, in the course of ages, it will become necessary to attend to them, and they have been calculated in advance. The expression for the greater axis of the orbit contains no inequality of this kind. This likewise is the result of theory. The cause of all these extremely curious facts has been explained by La Place, who was led to them by the discovery of the original cause which produced the secular equation of the moon. For the secular equations of the other celestial bodies, see their respective names, and **SECULAR**.

**EQUATION-Clock**, in *Horology*, is a clock contrived so as to indicate both *mean* and *equated* solar time, and consequently their difference, which at any instant is the *equation of time*. Various contrivances have been invented to answer this purpose by ingenious men, who at one time were seized with a rage for inventing such useless appendages of the clock, but the dictatorial power of fashion has nearly banished such superfluities, that are now considered as mere matters of curiosity. For a description of a clock of this sort by Enderlin, see our article **CLOCK**, and *Plate XXIV. of Horology*.

**EQUATION-Mechanism**, in a planetarium or orrery, is a mechanical contrivance for representing the alternate accelerations and retardations of motion in the requisite parts of the respective orbits of the different planets, which contrivance has been variously effected by different ingenious men. If

the motions of the heavenly bodies had been in concentric circles, and perfectly equable in every point of their orbits, the construction of a common planetarium would have been well calculated to exhibit all the phenomena in a natural and exact manner, provided the trains of wheelwork were accurately calculated for the respective periods, and the length of the arms proportional to the respective distances; but as all the planets that have considerable excentricity, and consequently considerable equations of the centre alternately *plus* and *minus*, have their motions constantly varying in angular velocity, a common planetarium, without equation-mechanism, is a very imperfect machine, and by no means competent to solve any of the phenomena, in a particular way, that depend on the relative velocities; for when the heliocentric motions are improperly represented, the geocentric appearances depending on them are deranged, and no dependance can be placed in the *times* pointed out of the apparent conjunctions, oppositions, stations, retrogradations, longitude, or latitude of any of the heavenly bodies. For instance Mercury, which planet performs its period through the ecliptic in somewhat less than 88 days, instead of continuing 44 days in each half of its orbit, at opposite sides of the conjugate axis, as it does respectively in those at each side of the transverse axis, continues about  $55\frac{1}{2}$  days in the aphelion portion, and only  $32\frac{1}{2}$  in the perihelion portion, so that the times of conjunction with the earth or other planet, even allowing the motion of that planet to be equable, would from this cause alone become very irregular, exceeding or falling short of the mean synodic period by many days, according to circumstances. It is evident, therefore, that the variations of velocity depending on the equation of the centre of both orbits of two planets, one received from the other, require to be taken into consideration, and allowed for in the construction of any mechanism that professes to be accurate in the representation of planetary motion.

*Contrivances by Mr. Huygens.*—The earliest attempt that we have met with, to produce the requisite inequalities of planetary motion by mechanism, is that of Mr. Huygens, the Dutch mathematician and philosopher, which he has described in his Latin treatise on the construction of his *Automaton*, or self-moving planetarium; he has availed himself of two different applications of the same principle, that are respectively applicable to different degrees of inequality of motion, that the excentricity of an orbit may require; his account and demonstration of both which methods we shall give in a free translation from his own words, which will probably be interesting to those who cannot read the original; particularly as there has been no notice taken of them by any writer, or instrument-maker, except perhaps Rowley, during the last century.

“It remains now,” says our very ingenious author, “that we explain how the true anomalies may be represented by wheelwork; for this purpose let ANP, *fig. 1. of Plate III. of Planetary Machines*, be the orbit of a planet, the centre of which is C with the sun at S, and let the point E be taken any where in the line SC, so that the excentricity SC may be to the radius CA, as CE is to ED; with which radius and centre E let the circle DM be described. Now let it be understood, that upon the centre of the circle AL there be fixed immoveably the contrate wheel DM with equal teeth, which therefore will necessarily revolve round the point C as a centre; let it be also supposed that the arbor of the long pinion KH be directed to C, and turned equally with its teeth adapted to those of the wheel DM, which will agree sufficiently, although on account of the excentricity of this wheel it will not always have the pinion at right angles; by this motion, I say, a planet will be

## EQUATION.

be carried unequally in its orbit, and in such a manner that its motion will very nearly correspond to Kepler's hypothesis; For having taken in the circle  $DM$ , described from the point  $E$ , any arc  $DO$ , let the teeth of that arc pass over to the line  $CD$  by turning the pinion  $KH$ , and the line  $CO$  will coincide with the line  $CAD$ , but not so that the point  $O$  may fall on the point  $D$ , but within at  $R$ , because  $CD$ , which is equal to both  $CE$  and  $EO$ , is greater than  $CO$ : now whatever may be the angle  $OC D$ , such will be that over which the line  $CAD$  has moved round the centre  $C$ ; therefore if we make the angle  $DC T$  equal to the angle  $DC O$ ,  $CT$  will be the right line into which  $CAD$  will have advanced, so that the planet will have proceeded from  $A$  to the point  $N$ , where the right line  $CT$  cuts the circumference of the circle  $AN$  described from the centre  $C$ . But the circle  $DM$ , having its centre  $E$  advanced to  $F$  by making  $FT$  equal to  $ED$ , will have the same situation as the circle  $TR$ : and it appears that on account of the equality of the angles  $OC D$  and  $DC T$ , the arc  $DM$ , which the right line  $CT$  cuts in the circumference of  $ODM$ , is equal to the arc  $DO$ ; so that  $M$  and  $E$  being joined, the angle  $MED$  will be equal to  $DEO$ . If, therefore, the arc  $AL$  be made to contain as many degrees as the arc  $DM$ , and  $CF$  be joined, this line will be parallel to  $EM$ .

"In the triangles  $CEM$  and  $SEL$ , therefore, the angles  $LCS$  and  $MEC$  will be equal, and the subtending sides proportional; for by construction  $SC$  is to  $CL$ , as  $CE$  is to  $EM$ ,  $CL$  being equal to  $CA$ , and  $EM$  to  $ED$ . Also the angles  $MCE$  and  $LSC$  are equal, and consequently the lines  $CM$  and  $SL$  are parallel.

"Now by this rotation of the circles  $DM$  and  $AL$ , the planet placed in  $A$  will be moved through the circle  $AL$ , very nearly according to Kepler's hypothesis, as may be thus shewn. Let the planet be supposed to have moved from  $A$  to  $N$ , the space or area  $NSA$  will be equal to its mean anomaly; but seeing the lines  $SL$  and  $CN$  are parallel, the triangles  $NSC$  and  $CLN$  will be equal, at least their difference will be insensible; the space or area, therefore,  $CLA$ , and consequently the arc  $AL$ , will answer to the mean anomaly when the planet has advanced from  $A$  to  $N$ . If, however, we make  $AQP$  the elliptic orbit of Kepler, the planet will be in  $Q$ , where the perpendicular  $NQ$  falling on  $AP$  cuts the ellipse  $AQP$ , and not in  $N$ ; but the ellipses are so like circles, that the variation in a machine is imperceptible,  $N$  will, therefore, be the true place of the planet corresponding to the mean motion  $AL$ , which arc is equal to  $DO$  or  $DM$ .

"Again, if the pinion be placed in any other point, as at  $G$ , equally distant from the centre  $C$ , to which the arbor is directed, and the point  $D$ , which is the most distant from the centre  $C$ , in the wheel  $ODM$ , be placed under the pinion, the planet being again at its aphelion  $A$ , it appears that the same angles are formed round the centre  $C$  by an equable motion of the pinion placed in  $G$  as in  $D$ . Wherefore in whatever situation the pinion be placed, the motion of the planet will be unequal, notwithstanding the teeth of the wheel  $DM$  are made equal among themselves, provided the pinion that points to the centre  $C$  have its teeth made long enough to act with all the teeth of the wheel which come successively to it at different distances from the centre  $C$ , and provided that the planet be put to its aphelion point of its orbit, when the longest line, or radius, drawn from  $C$  to  $DM$ , is in contact with the pinion.

"But since in our machine (automaton) all the pinions are placed on one common arbor, it cannot be placed properly towards the centres of more than two planets; we must, therefore, consider how the same effect can be produced

by *unequal teeth*: for this end let us suppose the circle  $DM$  divided into the equal parts  $Da, ab, bM$ , and  $Mg$ , and right lines be drawn to them from the point  $C$ , these lines  $Ca, Cb, CM, Cg$ , will divide  $ANL$ , the orbit of the planet, into the unequal parts  $Ad, de, eN, Nf$ . By this method as many unequal teeth may be determined in the circle  $ANL$ , as there are equal ones in the circle  $DM$ . If now the pinion be applied to these teeth, cut into the same number as in the former case, they will work together pretty well, though some are too large and others too small for the pinion, and the wheel  $AN$  will move unequally as the wheel  $DM$  did before, which has been proved to be according to the hypothesis of Kepler."

This is a faithful translation of Mr. Huygens' account and demonstration of his two methods of representing the irregularities of a planet's motion in its orbit, concerning which we have to observe, that, though both of them manifest great ingenuity as to the originality of the projects, yet they fall short of producing separately that full effect which he attributes to them, and which he seems to have credited; whereas the truth is, that instead of effecting the whole equation of the centre, the methods just described effect each only *one half* thereof; for agreeably to Kepler's theory, which supposes equal areas in equal times, bishop Ward has proved that *double the eccentricity* of a planet's orbit subtends very nearly its greatest equation, and that, according to his elliptic hypothesis, which is an excellent approximation to the truth, if the angular velocity of a planet round one focus of the ellipse be uniformly equable, its angular velocity, as seen from the other focus, will be so unequal, that one will represent the mean and the other the true or equated anomaly very nearly; but the distance between the two foci of any ellipse is its eccentricity laid off both ways from the centre, or *doubled*; whereas the method of Mr. Huygens' proposes the eccentricity to be taken only *once*, so that he has demonstrated rightly enough, but from wrong data; for if he had made the distance  $CE$  equal to double the eccentricity, then the whole of the equation would have been very nearly represented. The demonstration which Mr. Olinthus Gregory of Woolwich, then of Cambridge, has given in the 2d vol. of Mr. Nicholson's Philosophical Journal of the 8vo. series, to which we beg leave to refer, has proved with great perspicuity what the Rev. W. Pearson of Parson's Green had before asserted, that "the eccentricity of any planet's orbit is very nearly equal to the sine of one half only of its greatest equation." It may be considered as a singular circumstance that a man of Mr. Huygens' genius and mathematical skill, whose whole life was devoted to the sciences, should not discover that the methods which he so ingeniously devised to exhibit a planet's equated motion, produced but one half of the grand equation; and equally singular, perhaps, may it be considered, that no one before the writer of this article has detected the deficiency. When both these methods of constructing a planetary wheel are *united*, the full effect will be produced; or either of them may be united with any other contrivance that produces only one half the equation.

*Mr. Roemer's Contrivance.*—The next contrivance that we have met with, for representing planetary motion, is that of Roemer, who was mathematician to the king of France in the time of Mr. Huygens; this contrivance is detailed in Mr. Nicholson's Journal, vol. 4. of the 4to. series, by a correspondent, who translated his account from the French of "Machines and Inventions approved by the Royal Academy of Sciences for 1699," and who, in our opinion, speaks better of it than it deserves. The plan proposed might answer for one planet only, but is not applicable to a number of planets at the same time, for the planetary wheel proposed

## EQUATION.

is intended to be so thick as to constitute the frustum of a cone, on the surface of which a diagonal elliptical line is to be drawn round it, from the smaller to the larger diameter and back again, in which line the teeth are to be formed, after they have been laid down by a pair of dividers from a diagram previously made; so that, setting aside the tediousness of making such a wheel by the mechanical manipulation described; there could not be a number of these wheels brought into action by any of the usual arrangements of wheelwork, seeing the pinions that are to act with them must necessarily be conical also, and be the drivers in every case, which the requisite calculations of the trains in planetary machines will not always admit, where the extreme ratios of relative velocity are so widely different from each other. This plan, therefore, of exhibiting unequable motion in a planetarium, or orrery, must be considered among those projects of ingenuity which are more plausible in theory than serviceable in practice, and no doubt was abandoned for the reasons that have been here stated; which are our reasons for passing over it without further notice.

*Dr. Desaguliers' Contrivance.*—The next mechanism in the order of time, as far as we know, was Dr. Desaguliers' elliptic pulleys, or oval wheels with grooves at the circumference, and an endless cat-gut surrounding them, as described under our article COMETARIUM. This was certainly a scientific contrivance, and admits of application where the excentricity of the orbit is great; for the excentricity and shape of the pulleys may be made exactly similar to the excentricity and shape of the orbit to be represented. The principal objection to the adoption of this invention in a planetarium, is the liability of the cat-gut to contract and elongate with the variations of moisture in a room, and consequently to be sometimes too tight for the pulleys, and sometimes too loose, so as not to perform their office of giving motion to the elliptic plates. We have seen the elliptic plates with their edges cut into teeth, which is a great improvement in the contrivance; and where the excentricity is not very great, a pair of excentric circular wheels will act together very well, to answer the same purpose, as we shall have occasion to shew presently.

*Mr. Adam Walker's Contrivance.*—Another method of exhibiting planetary motion we have witnessed in the philosophical lectures of Mr. Walker, senior, which, if we recollect perfectly, was effected thus: A wooden board was shapen nearly into the form of an epicycloid, and had equal teeth cut on its circumference by hand, with an arm fixed fast to one of its extremities, that carried the stem of a planet, or of a ball to represent a planet; then a pinion was fixed on the surface of an inclined plane, down which the epicycloidal wheel was suffered to slide by its own weight, in a detached state, till its teeth came in action with the teeth of the pinion; and a motion given to the pinion by a handle, made the wheel, thus circumstanced, to revolve with unequal velocities, accordingly as its central point was near to, or removed from, the pinion, during its revolution in this sliding state; thus were not only the accelerations and retardations of motion alternately exhibited, but also the variations of distance, as they regarded the sun's ball fixed in the focus of an elliptical board, placed over this mechanism, and divided into twelve triangular areas, so that the planetary body was seen to move through the twelve sectors, coloured alternately white and black, in a manner corresponding to the same number of revolutions of the pinion; and to perform apparently equal areas in equal times. It is hardly necessary to observe on this contrivance, that, however convenient it might be to illustrate in a general way the nature of planetary motion to an

audience, it is obvious that detached wheels acting thus at liberty cannot be introduced into any machine that gives motion to a system of bodies, where their apses cross one another in various directions, and would require as many inclined planes as there are planets to be represented; likewise the planetary arms would require to be attached to wheels in every instance, though the calculations of the ratios of velocity might, and, according to the general constructions, would require in some instances pinions to be the last movers; all which difficulties in practice are insurmountable. The shape of the planetary wheel, we have understood, was not determined geometrically, nor yet by calculation, but by a repetition of manual rectifications of the figure till it was found to correspond with the areas previously delineated.

*Mr. Joseph Priestley's Contrivance.*—When Dr. Birbeck was appointed professor to succeed the late Dr. Garnet, at Anderson's University in Glasgow, his friend, Mr. Joseph Priestley of Bradford, contrived an orrery, which was made for him by a watch-maker at Halifax, of the name of Thomas Lister, which orrery the doctor has lately brought with him to London, on quitting the said professorship. It was finished in the year 1801, and will be described in its proper place with the other planetary machines. The inequalities of motion in this machine are produced by two separate methods; the two superior planets Saturn and Jupiter have their equations effected by inequalities made in the teeth of the last moving wheels; but the others have their equations, with the exception of the earth, produced by a contrivance which is at the same time novel, simple, and accurate enough for mechanical representation. The inventor has been kind enough to comply with our request of his giving us an account of his mode of producing unequable motion by mechanism, which account we shall present to our readers in his own words. The figure to which he refers, is *fig. 2. of Plate III. of Planetary Machines.*

Let  $A P B$ , says Mr. Priestley, be the orbit of the planet,  $O$  its centre, and  $S$  and  $F$  the two foci; in the former of which the sun is supposed to be placed. On the other focus  $F$ , as a centre, describe a circle  $D E p$ .

Let  $P$  be any given place of the planet in its orbit; draw  $F p$ , cutting the circle  $D E p$  in  $p$ . Now, agreeably to the hypothesis of Ward, it will be,

As the periodical time of the planet,  
Is to the time of its passing from  $A$  to  $P$ ;  
So is 360 degrees,  
To the angle  $E F p$ .

Hence, if a point  $p$  be made to revolve equably in the circle  $D E p$ , described on the lower focus  $F$  of the orbit, performing one revolution in the periodical time of the planet; and if, at any given time, the point be found at  $p$ , then a line drawn from the focus  $F$  through  $p$ , will cut the orbit of the planet in  $P$ , its place at the same time.

There are different ways of adopting this hypothesis in machinery. The first I shall mention, will immediately occur to any one viewing the figure. Let a wire, something longer than  $F B$ , be made to revolve equably round  $F$ , in the time representing one revolution of the planet. On this wire let a stud  $P$  be made to slide freely, and confined to move in the orbit  $A P B$ ; then the motion of the stud will, very nearly, represent that of the planet.

In the construction of an orrery, where each planet will require a separate arm  $F p$ , moveable on its peculiar centre, with the slider  $P$  confined to its own orbit, it may not be easy to contrive the whole so as to prevent one part of the machinery from interfering with another; nor can this method be conveniently used, where the wheels carrying the

## EQUATION.

arms are rims. The following construction has been found to answer the intention, and the motion to be very free and regular.

Let  $E \rho D$  be the toothed rim moving equably, the time of a revolution representing that of the planet. This rim may have any convenient diameter, not differing greatly from the orbit. Upon this rim, or on any projection attached to it, is fixed a pin  $C$ , round which one end of a bar  $CP$  moves; on the other end of the bar is fixed a perpendicular wire, or stem  $P$ , which carries the planet. This stem is confined to move in the orbit  $APB$ ; and, during its revolution, is made to rise and fall, so as to shew the inclination of the orbit to the ecliptic. The bar  $CP$  may be made of any convenient length; and the pin  $C$  should be so situated, that when  $P$  is at  $\rho$ , the bar becomes a tangent to the circle  $E \rho B$ . This is necessary, that the end  $P$ , in its vibrations on  $C$ , may be always found, as nearly as possible, in the line  $F \rho$ ; and on this account, the length of the bar should be as great as circumstances will conveniently admit.

*Contrivances by the Rev. William Pearson.*—Some time previously to the year 1796, the Rev. William Pearson, who lived at that time in the city of Lincoln, had read the accounts of Mr. Benjamin Martin's and Mr. James Ferguson's planetary mechanism with such attention, as enabled him to discover many imperfections in them, which it appeared to him might be avoided, and among the rest that defect which arises from equable motion and unvarying distance. On entering into a correspondence with one of the instrument-makers in London, he found that the modern machines owed their origin chiefly to one or the other of the above-named authors, and that little or no improvement had been made in the accuracy of their representations since their time. In consequence of this information, and unacquainted with the contrivances we have just described, except that of Dr. Desaguliers, described by Mr. Ferguson, he turned his mind towards the subject with a view of devising some improvements in this kind of machinery, which required an union of mechanical skill, with a knowledge of the science of astronomy, to enable him to strike out original plans for the accomplishment of his purpose. His first object was to render the trains of wheel-work as nearly as possible such as would produce the true periods of the different planets in their orbits, in doing which he found no difficulty after he had adopted a direct and unerring system of calculation, which became easy and familiar by practice; but this part of his pursuit is not the object of our present article: the next object of his attention was to devise the mechanical means of exhibiting planetary motion, both with regard to variable velocity and variable distance; different methods presented themselves in succession at different times, some of which he afterwards found had been tried before by others, but the first project that promised to be really subservient to his purpose was that which was represented in *fig. 3. of Plate III. of Planetary Machines*, and which was made for the arm of Mercury, in an orrery constructed under his direction, by a clock-maker at Lincoln. The contrivance had three objects in view, the variable distances, the variable velocities, and the latitudes of the planets, or deviation from the ecliptic, two of which purposes it answered most completely, and the third in a certain degree, besides preserving, fourthly, the parallelism of the planet's axis in every part of its orbit. It occurred to the contriver of the mechanism in question, before he had ever seen Mr. Adams's "Geometrical and Graphical Essays," and before he had heard of "Suardi's Geometric Pen," that if a small arm were by any means made to revolve in a retrograde direction, when placed at the distant end of the

long arm, or radius vector of any planet, during the time that the radius vector itself revolved just once by a direct motion round the sun in the centre, the curve traced by a pencil placed at the remote end of the small arm would be an *eccentric circle*; and also that there would be an alternate acceleration and retardation of angular velocity in the pencil with respect to the sun, or central point round which the radius vector might be carried; which velocity would be the quickest when the pencil was in its nearest situation, and slowest when most remote; because in the former case, the compound motion would be the sum of two motions, both in the same direction, and in the latter the difference of two motions in contrary directions. This idea, having at the moment of its occurrence made a strong impression on the mind of the inventor, excited in him much impatience to have it brought to the practical test of an experiment; the small frame, shewn in *fig. 3.* was roughly put together, and the equal wheels  $A$ ,  $B$ , and  $C$ , were included, so that  $A$  was fast to the arbor  $S$ , but  $B$  and  $C$  revolved on their arbors in the frame; the arbor of the latter, however, was left long enough for its pivot to protrude downwards, and to receive a crank-piece  $P$ , bearing a short pencil: the stem or arbor  $S$ , having its conical point at  $S$  fixed on a sheet of paper, was then held fast by a milled nut above it, to prevent its revolving, and the frame was carried round while the three small wheels, with equal numbers of teeth, were connected together; the consequence was, as had been expected, that the pencil traced a circle of a diameter equal to twice the distance of the arbors  $A$  and  $C$  from each other, but the centre of the circle was found to be at  $G$  instead of  $S$ , just the length of the short arm or crank-piece  $P$ , from the point  $S$ , from which the eccentric circle was described. This fact determined at once that the frame and short arm ought to be to each other in length as the mean distance is to the eccentricity of the orbit of any planet thus to be described, and, as orbits with but little eccentricity are very nearly *eccentric circles*, a circle thus described cannot be discriminated in a machine from an ellipse of the same eccentricity.

Before we proceed to describe the mechanism resulting from the principle of a little arm revolving backwards on the end of the radius vector of any planet just once in each revolution of the planet, let us illustrate the principle itself more clearly. Suppose the line  $AC$ , in *fig. 4. of Plate III.* to represent the length of the frame or radius vector  $SC$ , and also the short arm  $CA$ , representing the eccentricity or distance from the centre to the focus of the orbit, to be both directed into one right line  $SA$ , before any motion be communicated to the frame; then as the teeth of the three wheels  $A$ ,  $B$ , and  $C$ , of equal numbers of teeth, are connected together, and the wheel  $A$  is at rest, the wheel  $B$  will have a motion in the same direction as the frame, and the wheel  $C$  will have its motion in a contrary direction, but of the same velocity; conceive the centre of the wheel  $C$  to be carried along the circumference of the concentric circle  $COIE$ , the space of the quadrant  $CO$ , this wheel  $C$  by means of its connection with the wheel  $A$ , through the medium of wheel  $B$ , will in the same time have made a quarter of a revolution, and the remote end of the small arm attached to this wheel will be at  $N$ , at right angles to the radius vector, after having passed along the quadrant  $AN$ , of the eccentric circle  $ANPE$ , of which the point  $G$  is the invisible centre, and during the whole continuance of these two equal but contrary motions of the radius vector and short arm, through these quadrants respectively, the latter will have preserved itself parallel to its original situation  $AC$ ; again, while the radius vector is moving through the three remaining quadrants of the concentric circle

## EQUATION.

circle from O to I E and C, successively, the remote end of the small arm will describe the three corresponding quadrants of the excentric circle from N to P, M, and A, in equal portions of time, and its parallelism will still be preserved throughout the whole circle, as seen in the figure. Thus, while the centre of the wheel C describes the concentric circle COIE round the point S with an equable motion, the remote end of the small arm, supposed to carry a planetary body, will describe the excentric circle ANPM, during the whole of which time the motion of the planet will be equable as it respects the point G or centre, but unequable as it respects the point S out of the centre, where the sun is supposed to be placed: for conceive lines like SN to be drawn from S to the planet in different parts of the circle ANPM, or orbit, and they will intersect the circle COIE behind the remote end of the radius vector in one half of a revolution, and before it in the other, and the angle at S, subtended by the short arm in any situation, will express the equation of the centre in that point of the orbit, which equation, therefore, is additive to the mean motion of the radius vector in one six signs of anomaly, and subtractive from it in the other six. The nature of the alternate retardation and acceleration of motion produced by this mechanism round the point S, and also the variation of distance, may be easily apprehended by attending to the successive retrograde and direct motions of the arm in each revolution of the radius vector; from A to N these move in opposite directions, and the difference of their velocities, as viewed from S, is equal to the quantity of retardation in any particular point of this quadrant; at N the difference is nothing, in which situation of the arm the equations would be a maximum if the arm were perpendicular to the line SN, i. e. if SN were a tangent, to the circle of which the arm ON is radius; but this will not happen till the radius vector has advanced beyond the space of an exact quadrant, and the arm has come to *n*, where the angle subtended at S by the arm will be the greatest possible.

The distance of this point, where the equation is a maximum from 90° of mean anomaly, will evidently depend on the relative proportions in length of the radius vector and short arm, or which is the same thing, of the mean distance and excentricity of the planet to be represented. From *n* to P, through the remainder of the first semi-circle, the radius vector and arm will both move in the same direction, and will cause an acceleration which will be greatest at P, the perihelion point, where they will both be again in a right line, shortened by double the whole length of the short arm, as compared with the original situation at the aphelion point. From the perihelion to the point of greatest equation at the opposite side of the orbit, the motions of the radius vector and arm continue to be in the same direction, but through the last quadrant and a small portion of the third, the directions are again opposite till the planet arrives at the aphelion point A, where it has undergone all its changes of velocity and distance, and where it commences the same alternation of slow and quick motions that were before exhibited.

Thus, if S be considered as the sun, A the place of the aphelion of any planet, P its perihelion, *m* and *n*, in the small circle of the arm, the places of mean motion, the concentric circle COIE the ecliptic, and the excentric one ANPM the planet's orbit, it is evident that both the excentricity, and also a certain equation of the centre of a planet's orbit, may be very conveniently represented by the same apparatus that has long been used for no other purpose but that of preserving the parallelism of its axis.

But still the main question is not disposed of; viz. what

portion of the equation, considered as an arc of the orbit, will a line equal to the excentricity subtend? The analogy for resolving this query is as follows:

As the mean distance, or radius vector, of the planet,  
Is to radius,

So is the excentricity, or short arm,

To the sine of the greatest angle at S subtended by the short arm.

This angle, taken in degrees and minutes, we find is invariably, as nearly as may be, *one-half of the greatest equation*, as has been already mentioned.

It will now have occurred to the reader, probably, that, if a line equal to the excentricity subtends one-half the equation of the centre of a planet, double the excentricity will be the measure of a short arm that will subtend the whole equation; this is nearly true as to the question of the equation alone, but then the distances and excentricity of the orbit, on which the geocentric appearances depend, would be greatly out of proportion; and what is gained in the heliocentric apparent places would be lost in the geocentric appearance in the system. To keep all the desiderata within their due bounds, and to make the elements of the orbit accord with both heliocentric and geocentric appearances in the mechanical representation, an additional contrivance was superadded, which supplied the defect of the revolving short arm without deranging materially the effect of its operation; the last wheel of the train, which carries the radius vector round in the due period, had its teeth so unequally cut as to represent the second half of the equation, by causing an alternate acceleration and retardation in the revolution of the radius vector itself, so that the total effect produced by these two contrivances acting together was very nearly agreeable to the real motion of the planet itself in its own orbit. But we have said, that the latitude of the planet was represented by the same contrivance that shews the distances and one-half of the equation. This was done by placing the stem of the planet in a square socket, at the remote end of the small arm, in so detached a way, that it was at liberty to rest on the plane of an inclined plate, carried by the radius vector, to represent the inclination of the orbit, and to receive the circular scale of latitudes pointed to by the end of the stem as it travelled up and down the said plane in its retrograde revolution.

The little frame we have had occasion to mention might do very well as a piece of mechanism for a radius vector, where the length is small, but where the planet is represented as moving at a considerable distance from the sun, the mechanism contained in *fig. 3. of Plate IV.* is better adapted, where A B is the radius vector proportional to the mean distance, and embracing fast the upper extremity of the tube of the wheel with unequal teeth; C is a contrate wheel of any number of teeth made fast to a surrounding tube that has no motion; the horizontal arbor D has two pinions of equal numbers, no matter what, one of which, E, is connected with the fixed wheel C, and the other, F, is connected with a second contrate wheel G, which is every way like the wheel C, except that its position is inverted for the sake of making its direction of motion retrograde; the lower pivot of wheel G rests in a cock H, attached to the end of the radius vector, and its upper pivot ascending above the same carries the short arm that supports the stem of the planet; lastly, I is the inclined plate with a scale of latitudes, on which the end of the stem rests, and by which it is made to ascend through one portion of its orbit, after which its own weight brings it gradually down again. The inclined plate is so placed that the nodes may fall at their

# EQUATION.

respective distances from the aphelion point; and all the changes of place arising from the combined causes of varying distance, varying velocity, and inclination of the orbit, are duly represented.

A similar combination of mechanical contrivances was afterwards, in the year 1802, adopted by Mr. Pearson, when he contrived and superintended the construction of the large planetarium at the house of the Royal Institution in Albemarle Street, London; though the means are somewhat different. The plane of the instrument was desired by Dr. Thomas Young, at that time the lecturer, to be vertical instead of horizontal, which afforded the means of making the short arms, representing the respective excentricities revolve backwards by a weight suspended to each, instead of the wheel-work which we have described: the inequalities among the teeth of the tubed wheels in this instrument effect one half of the equation, and the retrograde revolutions of the little arms produce the other, and make all the planets revolve according to equated motion, while the stems round which the said short arms revolve are, agreeably to Dr. Young's suggestion, so bent, as to represent also the inclination of the orbits, and consequent heliocentric latitudes, for estimating which the ecliptic plate is put exactly in the plane passing through the centre of the sun, or coincident with the plane of the earth's orbit. The small divided plates carried by the ends of the radii vectores indicate both the equations and heliocentric latitudes; which observations we make here, because the construction of the instrument has never yet been publicly explained, except perhaps partially in the lectures, and because the uses of the different parts, not being obvious by mere inspection, are as yet but little understood. For a more particular description of this instrument, see our article PLANETARIUM.

But we are not to take for granted, because one half of the greatest equation will be thus represented at the point of mean distance by a radius vector and short arm, that are to each other as the mean distance to the excentricity, that therefore half the equation will be equally well represented in every other part of the orbit of a planet. Let us examine this matter more particularly, and bring it to the test of actual calculation. Let the line  $SH$ , *fig. 5. of Plate III.* be the radius vector of Mercury, and  $HA$  the short arm representing the excentricity, which are to each other very nearly as 5 to 1; then when the planet is at  $A$ , its greatest distance from  $S$ , the sun, it is obvious from what has been said, that its angular velocity, as it respects  $S$ , must be slower than if it were at  $P$ , or any other part of the line  $SA$ ; conceive now the point  $H$ , round which the little arm revolves, to move forwards so far that the planet may fall back by means of the arm to the point  $a$ ; then if a line were drawn from  $S$  to  $a$ , the equation or angle at  $S$  would be subtended by  $ab$ , the sine of the angle  $AHa$  to radius  $AH$ , which line consequently is perpendicular to the radius vector at the point  $b$ ; the distance  $bH$  is the cosine of the same angle, and we have  $SH + Hd$  for the base of a right-angled triangle, and  $ba$  for the perpendicular of the same, to determine the angle at  $S$  or semi-equation, which is one of the simple cases in plane trigonometry, where the base is used as radius, and the perpendicular as tangent of the required angle. For example, the mean distance of Mercury, as given by La Lande, is 38710, and its excentricity 7955.4, the mean distance of the earth being 100000; then if, agreeably to this ratio, we take the small arm representing the excentricity at unity, the radius vector must be 4.86587; for as 7955.4 : 38710 :: 1 : 4.86587; let the point  $a$  now be taken equal to  $30^\circ$  from  $A$ , and from the tables of natural

sines we have  $ab = .500000$  and  $SH + Hd = 4.86587 + .8660254 = 5.7318954$ , hence  
 As log. 57319 - Ar. co. - .2417014  
 Log. 5000 - - - - .6989700  
 Tang. of  $\frac{1}{2}$  equation  $4^\circ 59' 7''$  . 9406714

In the same manner one half of the equation, corresponding to any other point  $c$  in the quadrant  $AQ$ , may be found where  $Hd$  is the cosine to be added to the radius vector, and  $cd$  the sine which constitutes the subtense of the required angle at  $S$ . In the second quadrant from  $Q$  to  $P$  the radius vector minus the cosine becomes the base of the triangle at any point  $e$  or  $g$ , but the sines at those points are the perpendiculars  $ef$  and  $gb$ , as in the last quadrant, so that the base of the triangles successively taken is constantly shortening from the aphelion to the perihelion points of the orbit, whilst the perpendiculars are increasing in the first quadrant, and then decreasing in an inverted order in the second, which circumstance makes the equation greater in a given quantity of mean motion near the perihelion than near the aphelion, as the Newtonian theory requires. That a due estimate may be had of the effect produced by this mechanism in every part of Mercury's orbit, we shall subjoin a small table containing the data and result of corresponding calculations for every ten degrees of mean motion; and parallel to the semi-equations so obtained, we shall put a parallel column of half the equations taken from the best tables as published by La Lande, from which it will be seen that the errors, which at most are a small portion of the whole equation, are in excess from the aphelion or  $0^\circ$  to  $102^\circ$  of mean anomaly, and in defect from  $102^\circ$  to about  $258^\circ$ , then from  $258^\circ$  to  $360^\circ$  or  $0^\circ$  again in excess, which deviations from the truth are agreeable to the deviations arising from the approximation called the "elliptic hypothesis," which Buhald proved from four observed places of the planet Mars, as observed by Tycho Brahe, makes the computed places more backward than the true ones in the first and third quadrants of mean motion, and more forward in the second and fourth.

TABLE.

Dist. from the Aphelion	Base Line.	Perpendicular.	Dist. from the Aphelion	Corresponding Semi-Equations by Mechanism.	Semi-Equations by La Lande.

## EQUATION.

In examining the preceding table it may be seen that the place of mean motion, or point where the equation is a maximum, falls, according to the mechanism, somewhere between  $100^\circ$  and  $110^\circ$ , which, in La Lande's tables, is at  $105^\circ$ ; let us try where it will fall exactly by the mechanical representation.

The point B, where the line SB is a tangent to the small circle, is the place of the planet's greatest equation, and this point will be found beyond the first quadrant, a quantity equal to the angle QHB, or, which is the same thing, HSB, or greatest semi-equation; for as SHQ and SBH are both right-angled, and have the angle at S common to both, the third angle, HQS, is equal to the third angle BHS, and, consequently, the supplemental angle QHB is equal to the supplemental angle HSQ, or greatest semi-equation. *Q. E. D.*

But the greatest semi-equation by the mechanism when computed is  $11^\circ 51' 34''$ , therefore the place of mean motion falls at  $90^\circ + 11^\circ 51' 34''$ , or at  $101^\circ 51' 34''$ , which point is short of  $105^\circ$  by a quantity upwards of  $3^\circ$ . This want of exact coincidence is, however, of little or no moment in the mechanical representation of the orbit, because the quantity of the greatest equation is nearly stationary for many degrees both before and after the exact point of mean motion. The representation will be still more accurate where the orbits have less excentricity, than that of Mercury, which is the case with all the other planets, except two out of the four newly discovered ones, *viz.* Pallas and Juno.

As we have had frequent occasion in this article to speak of a wheel with unequal teeth, made for the purpose of effecting alternate accelerations and retardations of angular motion, and have also seen the theory explained by Mr. Huygens, it may be proper to say a few words here about the practical method of cutting such a wheel. This operation may be done by three different methods; first, the divided circle of the plate, to be used with the engine, may have the divisions laid down unequally by Huygens' mode of transferring equal divisions from an excentric circle to a concentric one, as already explained; and then the teeth may be cut in the ordinary way from these unequal spaces, when punched or drilled into dividing holes; or, secondly, an equally divided circle of the engine plate may be used, and the increments and decrements, previously calculated, may be given at each tooth by the micrometer screw of such an engine as either Hindley's or Rehó's; or, thirdly, which is the readiest method, the wheel to be cut may have a hole drilled in the excentric point, and be placed thereby on the arbor of the engine, till all the teeth are marked with slight notches by the cutter, adjusted for distance at each cutting, and then the hole in the centre must be used for completing the teeth in their proper direction; for when the cutter is put into the notches successively, it will cut the teeth towards the centre without any guidance of the index or alidade; and this method is practicable with any common engine without a micrometer screw for taking and giving small portions, as deductions from or additions to a mean tooth. For the wheels with unequal teeth in the large planetarium of the Royal Institution, in Albemarle street, London, the first method was used by the maker, McCulloch, under the direction of the contriver both of the machine itself, and of the method used of rendering the teeth of certain wheels gradually unequal round each separate semicircle, agreeably to the planetary motions to be produced thereby in the planets themselves; but in an accurate and elegant machine since made (by Fidler) for himself, the last method was used with success for the large

wheel that produces the sun's, or rather earth's annual equation.

Another, and that a very recently contrived method of exhibiting the equations of all the planetary orbits at the same time, together with their variable distances, by very simple mechanism, has been adopted by Mr. Pearson in the machine we have just mentioned, as made by Fidler, under his own direction; this method has the advantage of shewing also the mean motions, and is well calculated for illustrating the irregularities of motion on which the various phenomena of the heavenly bodies depend, as well as for shewing the exact times at which they occur, and the countries to which they will be visible. For a description of the machine itself we refer the reader to the articles PLANETARIUM and ORRERY, and satisfy ourselves in this place with an account of the principle by means of which the equations of the centre are effected. *Fig. 1. of Plate IV. of Planetary Machines*, which is illustrative of the principle in question, is derived from *fig. 4. of Plate III.* which has been explained, but has the addition of a third diminutive arm at the end of the longer arm placed at the extremity of the radius vector; we have seen that one arm, equal in length to the excentricity of the orbit to be represented, will, by its retrograde revolution, give the distances and one half of the equation, very nearly, in every part of the orbit, and we have seen that if the said arm were made equal to twice the excentricity it would give the whole equation near enough, but would not give the distances truly; now the introduction of the additional arm is to make the apparent place of the planet fulfil both these conditions, which it does in a surprising manner. Let S-J, in *fig. 2.* be a radius vector, revolving equably round the point S, in *fig. 1.* in which case the extreme end J will describe the concentric circle JKOLQRTV; let Ja be a short arm equal in length to the excentricity once and a half taken, which arm is made to revolve in a backward direction by means of the fast grooved circle *d*, of the catgut *ef*, and of the pulley *g* of the same diameter as *d*, which mechanism answers as well as that in *fig. 3.* before described, and is simpler: over the pulley *g* is fixed fast to a stem, borne by the radius vector, round which the pulley turns, another grooved circular piece J, round which the gut *bi* goes, and embraces also a diminutive pulley *a* of half the size of J, so that whilst the radius vector and arm Ja go each once round in contrary directions, the third or little arm aA, which is equal in length to only one half the excentricity, goes twice round in the same direction, in which the radius vector moves, and thus carries a planet at its extremity round the point S, in which the sun is placed, very nearly agreeably to the laws of planetary motion, with regard both to angular velocity and distance in every part of the orbit. To render the effect thus produced more intelligible, conceive two pins made fast in the line JA, *fig. 1.* considered as one line equal to twice the excentricity of the orbit to the radius SJ, and let one of them be at C, the middle of the line, and the other at A, the extremity; then if this line preserves its parallelism all round the orbit, by a retrograde motion given to it by the catgut *ef* and pulley *g*, *fig. 2.* the pin C being at the distance of the excentricity SG from the end J of the radius vector, will describe the excentric orbit 1, 2, 3, I, 4, 5, 6, of the planet, while the pin at A will have the proper velocity as seen from S, but will move in the circle ABDEP FMH, which is too excentric to become the true orbit; but if the point A of the additional small arm be put to C when the motion begins, and has the planetary body placed on its extremity, then it will move in the same excentric

## EQUATION.

circle as the first pin C, but with the apparent angular velocity of the second pin A as seen from the other focus W, and very nearly so as seen from the sun at S: for conceive the radius S J to have moved to K, the pin A will be found at B, on account of the angle B K b being equal to the angle J S K, which is here  $45^\circ$ , but the planet has moved a quadrant to 1, and is found in the circle described by the pin C, or middle circle; but, viewed from W, according to the elliptic hypothesis, is seen in the line W B, as though it had been actually at B in the outermost circle; again, when the radius vector has completed a quadrant and is in the situation S O, the first pin is at N, the second at D, and the planet at 2, in the line W D as before, and the additional arm has now described a semicircle: here the equation D S O is subtended by double the excentricity very nearly: when J is advanced  $135^\circ$  to L, the additional arm has moved  $\frac{3}{4}$  of a circle, and is found at 3, still in the middle circle, and also in the line W E, extended: and when S Q is the situation of the radius vector the planet is at I, the perihelion point of the middle circle, and also in the line W P, extended as before. In like manner in the other semicircle of mean anomaly, when the extreme end of the radius vector is successively at the points R, T, and V, the planet will be found at the points 4, 5, and 6, and also in the lines W F, W M, and W H, respectively, still moving in the middle circle, till it arrives at the aphelion point C, from which it originally set out. When the pulleys are made to produce this effect very nicely, the band or gut, that embraces two pulleys of different diameters, will affect the ratio of 1:2 in practice, and will require the smaller pulley to be somewhat less in diameter than what the exact proportion requires in theory. The radius vector has a slit in its remote end, with a thumb-screw under it, to fix the pulley at a greater or less distance, as the tension of the gut may require, and the whole contrivance being simple, steady in its motion, and light in its construction, as well as having a tendency to prevent the radius vector from bending downwards, is far preferable, in every point of view, to any contrivance we have before seen for answering the same purpose. The mechanical representation of the orbit bears the same analogy to the elliptic hypothesis, that an excentric circle does to an ellipse of the same excentricity, and in the orbits of the planets these figures are so nearly alike, that they may be substituted for each other, without sensible error; and we may add, that the equation produced by only one arm, equal to twice the excentricity, is by no means so accurate as the *equation doubled*, that is, produced from an arm equal to the exact excentricity, because the tangents of different angles do not increase by equal quantities.

Besides the preceding methods of producing the equation of a planet's orbit, our author has contrived to indicate the quantity thereof in any point of the orbit, as well as the latitude also, as seen from the sun; this is done by means of a hand fixed under the revolving pulley J, travelling over a divided and silvered plate, fixed fast in the situation of the dotted circle, on the end of the radius vector, concentric with the pulley, which plate not only shews the equation and latitude at any time, but is of use in placing the arms in their proper situations by the latitudes taken from the Ephemeris or Nautical Almanac.

These are all the methods that have fallen within our notice, of effecting the grand equation of a planet's orbit, as applied to an orrery, or planetarium; but there remain yet two pieces of mechanism, contrived by our present inventor, that are well calculated to explain in a lecture-room the equation of an individual planet, as detached from the system,

which we shall briefly describe, as being contrivances equally novel and competent to their purpose. The first is represented by *figs. 4 and 5* of our last plate, the former being a section of the wheel-work, and the latter a sketch of a part of the visible part of the instrument. AB is a little frame, containing four wheels, *a, b, c,* and *d*; *a* and *b* are equal in diameter, and of similar numbers of teeth, *a* fixed on the arbor of the handle *e,* and *b* on a tubed arbor *f,* that carries the index *g,* seen in *fig. 5* of the shape of a T, with a point touching the circle *k,* which is an elliptic circle; so that whatever velocity is given by the handle to the wheel *a* in an equable manner, the same is communicated, by the medium of the wheel *b,* to the index *g,* which therefore moves according to mean motion in the elliptic circle K. The wheels *c* and *d* are excentric, and have also similar diameters and numbers of teeth, but are placed to act so, that the longest radius of one always acts with the shortest of the other, and thus produce the same effect as Dr. Desaguliers' elliptic grooved plates with the endless catgut. The excentricity of the wheels bears the same proportion to their common radius, that the excentricity of the planet's orbit does to its mean distance: wheel *c* is fixed fast to the same arbor of the handle as wheel *a* is, but wheel *d* has a separate arbor, which goes with the tube of wheel *b,* and carries the hand *i,* and on its upper end a ball to represent the sun. The sectoral arc of the index *g* is graduated, for Mercury for instance, into  $24^\circ$  each way from the middle, to which the hand *i* must be put when the index points to that part of the elliptic circle in which the aphelion point of the planet is; then as the handle is turned the index shews the mean motion in the elliptic, which may have a second circle divided into signs of mean anomaly, beginning at the aphelion point, and as the motion proceeds the hand *i* falls back, till at the end of three signs and a half of mean anomaly it is found near the extremity of the sectoral arc, at *g*; at the perihelion point the hand is again in the middle; and at eight and a half signs of mean anomaly it will be in its present situation again, at its greatest equation, at the opposite end of the sectoral piece; and lastly, at the aphelion point the hand will be again found in the middle, which is the zero of both the positive and negative equations, which are respectively marked + and - on the opposite ends of the graduated sectoral arc. Thus, the index *g* shews the mean motion, the hand *i* the equated motion, and the graduated portion of the index has the quantity of the equation plus or minus, shewn by the hand *i* in every part of the orbit, while a line drawn from S, the sun, over the point of the hand *i* to the elliptic K, shews the equated or true heliocentric place of the planet. The other instrument for explaining the nature of the mean and equated anomaly of a detached planet, and of its equation, which is their difference, is simply a mechanical construction of the elliptic hypothesis of bishop Ward, and is represented by *fig. 6* of the same plate. S G W is an elliptic plate of wood or metal, described from the foci S and W, the small circle at S is divided into an elliptic circle with a slender stem in the centre bearing a ball to represent the sun, and the other similar circle at W is divided into as many spaces as there are days or weeks in the period of the planet; of which 88<sup>d</sup> are proper for Mercury; the bar *a* G is concealed under the dotted line, and turns on the vertical stem of the stand that supports the elliptical plate at G, by means of a piece of brass tube fixed at its end; on the bar *a* a sliding piece *b* is inserted, that bears a small pulley *c,* and a planet in the angular point behind it, on a stem as high as that of the sun; this sliding piece has two rollers, bearing against the edge of the elliptical plate, to facilitate the motion of the bar round the plate, which is produced by

## EQUATION.

hand; an endless gut or silk cord  $S W c$  draws the sliding piece close to the said plate, and causes the pulley and planet to describe the proper ellipse for the orbit. According to the elliptic hypothesis, if the angle  $c W A$  be the measure of the mean anomaly, the angle at the sun in the other focus, *viz.*  $c S A$ , will always be the equated anomaly, and the small angle  $S c W$  will, in every situation, be the equation of the centre, as being the supplement of the sum of the other two angles, that is, the external angle  $c W A$ , that represents the mean anomaly, is equal to the sum of both the internal angles of the triangle at  $S$  and  $c$ , as being respectively the supplement of the other internal angle at  $W$ ; but the internal angle at  $S$  is the equated anomaly; therefore the angle  $c W A - \angle c S W$  is the angle  $c$ , or equation during the first six signs of mean anomaly; in the other six signs the angle representing the mean anomaly at  $W$  will be smaller than the angle at  $S$ , representing equated anomaly, therefore the equation, or difference between them, which has been subtractive, becomes now additive; and the hypothesis, thus mechanically constructed, affords the ready means of explaining the particulars of planetary motion, for which purpose equal sectoral arcs are laid down on the plate alternately black and white, which the thread  $S c$  moves over in equal arcs of the circle  $W$ , moved over by the thread  $W c$ ; which are equal portions of time; and when the circle  $W$  is divided into days or weeks, and the circle  $S$  into signs of longitude, and also into signs of anomaly, the same results will follow as from the preceding mechanism, as nearly as may be, while, at the same time, all the variations of distance, as well as of the equation, will be faithfully exhibited. Both these contrivances may be constructed so as to be used either horizontally or vertically, and on any scale of magnitude that the audience of a lecture room may require.

*EQUATION of Time.* Having, under the article *DAY*, explained the origin of the difference between solar and mean time, we have now only to explain the method by which this difference is calculated.

To effect this, it is necessary to know precisely the motion of the sun, and the dimensions of its orbit: we may then calculate the arc which it describes every day in the year parallel to the equator. If this real and variable motion be compared with its mean motion, the difference will be the equation of time.

If we imagine two meridians, drawn through the two extremities of the arc of the ecliptic, which the sun describes in one day, the arc of the equator, which they intercept, is the difference between the solar and a sidereal day; for when the rotation of the celestial sphere is terminated, this small arc of the equator must traverse the meridian before the centre of the sun can arrive there. Now as this arc is not always of the same length, the solar days are not all equal.

Nor would they be so, even if the sun described every day an equal arc of the ecliptic, for these arcs take successively different inclinations relatively to the equator. At the moment of the equinoxes, they cut this plane at an angle equal to the obliquity of the ecliptic, and at the period of the solstices they are parallel to it. The meridians drawn through the extremities of these diurnal arcs are more separated at the solstices than if they contained the same arc at the time of the equinoxes; and, as it is this separation of the two meridians which measures the successive retardations of the sun, these are unequal, and less at the equinoxes than at the solstices. The daily variation of the motion of the sun in its orbit is another source of inequality, as it augments and diminishes the diurnal arc of the ecliptic, and this produces a corresponding variation in the arcs of

of the equator contained between the above-mentioned meridians.

Thus the inequality in the solar days arises from two distinct causes, the obliquity of the ecliptic, and the unequal motion of the sun in its orbit. As these two causes each produce their separate effect, they must be both destroyed, to render the solar days equal, that is, the motion of the sun must become uniform, and the ecliptic must coincide with the equator.

To calculate the value of the equation of time, we must calculate the arc which the sun describes each day on the ecliptic, and project it on the equator, and from this deduct the mean diurnal motion: the difference will give the equation of time for that day.

To represent these results geometrically, we may suppose an artificial sun to move in the manner described under the article *DAY*, the mean day is the interval between two successive returns of this fictitious sun, and the mean noon the instant of its passage over the meridian; and the mean equinox is the instant of its passage through the equinoctial point. It is obtained by a simple proportion, when the longitude of the perigee is known, and the epoch when the true sun is in the apses, the time which elapses between two consecutive returns to the mean equinox, forms the mean tropical year, and which is equal to 365,<sup>d</sup> 242250.

To calculate the place of the mean sun on the equator for a given instant, it is sufficient to calculate the mean longitude, and this, reduced to the equator, is the mean right ascension of the sun.

The projection of the true sun on the equator may either be determined from observation; or from calculating its right ascension. The difference between their right ascensions, reduced into time, in the proportion of 24<sup>h</sup> to 360°, indicates the interval between the passage of the true and mean sun, and is the required equation of time: it is sometimes additive, and sometimes subtractive, and has the remarkable property of becoming zero four times in a year.

To understand the reason of this phenomenon, let us imagine (*fig. 108.*) two suns,  $S^2$  and  $S^1$ , to set out at the same time from the equinox, both moving with an uniform motion; the one,  $S^2$ , in the ecliptic, the other,  $S^1$ , in the equator, and let the motion of each be referred to the latter plane.  $S^2$  will at first advance upon the meridian of  $S^1$ , but afterwards this latter will approach it, and they will arrive together at the solstice; after this the meridian of  $S^2$  will advance upon that of  $S^1$ , till the second equinox, where they will arrive together. The same circumstances will occur in the other half of the orbit, and thus the two suns will coincide together four times in the year, namely, at the equinoxes and solstices.

But, in reality, the mean sun does not set out at the same time as the true sun; they will not, therefore, meet at the same points; the unequal motion of the sun changes this difference, but these two causes united only change the epoch of the coincidences; their number remains the same.

Let us consider the motion of the two suns,  $S^2$ , and  $S^1$ , supposed to set out together from the autumnal equinox, and proceeding towards the perigee. The true sun,  $S^1$ , which describes the ecliptic, being referred by its meridian to the plane of the equator, will then be found behind the others, for it is preceded by  $S^2$  till the perigee; let us now consider the motion of the other two. Till the moment of the solstice,  $S^2$  precedes  $S^1$ , and  $S^2$  precedes  $S^1$ , their order is therefore  $S^1, S^2, S^1$ . At the solstice  $S^1$  joins  $S^2$ , and afterwards passes it; their order is then  $S^2, S^1, S^2$ , but at the perigee  $S^1$  coincides with  $S^2$ , and afterwards precedes it: to do this  $S^1$  and  $S^2$  must meet in the interval. The order then becomes  $S^1, S^2,$

## EQUATION.

$S^2, S^1$ ; thus between the winter solstice and the perigee the true sun  $S^1$ , referred to the equator, meets the mean sun  $S^2$ , and the equation becomes zero. From the perigee to the vernal equinox  $S^1$  precedes  $S^2$ , and  $S^2$  precedes  $S^3$ ; they none of them meet therefore in this interval. At the equinox  $S^1$  joins  $S^2$ , and their order becomes  $S^2, S^3, S^1$ ; but  $S^3$  cannot remain long between the two others, for at every quadrant the separation of  $S^2$  and  $S^3$  increases to  $2^\circ 24' 24''.4$ , as appears by calculation; but the distance of  $S^1, S^2$  never exceeds  $1^\circ 55' 27''$ , which is the greatest equation of the centre, and as, in the present situation of the solar orbit, this takes place near the equinoxes, the arc which corresponds to it on the equator is still less than it. It is evident, therefore, after the vernal equinox, and before the summer solstice, there must be some moment when the mean sun  $S^2$  arrives upon the meridian of  $S^1$ , when the equation is again zero. From that point to the summer solstice the order is as follows,  $S^2, S^1, S^3$ : at the solstice  $S^2$  joins  $S^1$ , and afterwards passes it. But  $S^1$  precedes  $S^2$  as far as the apogee, consequently the meridian of  $S^1$  joins the mean sun  $S^2$ , before the solstice, and the equation becomes zero for the third time.

From the solstice to the apogee, the order of the three suns is as follows,  $S^1, S^2, S^3$ ; at the apogee  $S^2$  joins  $S^1$ , and afterwards precedes it till the perigee, the order thus becoming  $S^1, S^3, S^2$ ; but at the autumnal equinox  $S^2$  joins  $S^3$ , and consequently meets in this interval the meridian of  $S^1$ , and the equation becomes zero for the fourth time.

The order of the three suns then becomes  $S^1, S^2, S^3$ , and the same appearances are re-produced in the same order as before.

Hence it appears, that in consequence of the obliquity of the ecliptic, combined with the unequal motion of the sun, the equation of time becomes zero four times a year, *viz.* once between the winter solstice and the perigee, twice between the vernal equinox and the summer solstice, and for the last time between the apogee and the autumnal equinox. The epochs of these phenomena evidently vary with the position of the greater axis of the solar orbit; at present they happen about the 24th December, 15th April, 15th June, and the 31st of August. If the equator coincided with the ecliptic, that part of the equation of time depending on their inclination would disappear, and the mean motion would only differ from the true by the equation of the centre, and mean and true time would agree twice a year when the sun is in the apsidæ.

Dr. Maskelyne has invented a rule for computing the equation of time, in which all the three causes are considered; it was investigated in the following manner.

Let  $A P L Q$  (*Plate XII. fig. 109.*) be the ecliptic,  $A L Q$  the equator,  $A$  the first point of Aries,  $P$  the point where the sun's apparent motion is slowest,  $S$  any place of the sun; draw  $S v$  perpendicular to the equator, and take  $A n = A P$ . When the sun begins to move from  $P$ , suppose a star to begin to move from  $n$ , with the sun's mean motion in right ascension or longitude, *viz.* at the rate of  $59' 8''$  in a day; and when  $n$  passes the meridian, let the clock be adjusted to 12; take  $n m = P s$ , and when the star comes to  $m$ , if the sun moved uniformly with his mean motion he would be found at  $s$ , but at that time let  $S$  be the place of the sun. Let the sun  $S$ , and consequently  $v$ , be on the meridian; and then as  $m$  is the place of the imaginary star at that instant,  $m v$  must be the equation of time. The sun's mean place is at  $S$ , and as  $A n = A P$ , and  $n m = P s$ , we have  $A m = A P s$ ; consequently  $m v = A v - A m = A v - A P s$ . Let  $A$  be the mean equinox, or the point where it would have been if it had moved with its mean velocity, and draw  $A z$  perpendicular to  $A Q$ : then  $A m = A z + z m = A a \times \cos z A a + z m$ : or because the cosine of  $z A a$ , the obliquity of the ecliptic  $23^\circ 28'' = \frac{1}{2}$  very nearly,  $A m = \frac{1}{2} A a + z m$ : hence  $m v = A v - z m - \frac{1}{2} A a$ . Here  $A v$  is the sun's true right ascension;  $z m$  the mean right ascension, or mean longitude; and  $\frac{1}{2} A a$  (*viz.*  $A x$ ) is the equation of the equinoxes in right ascension; therefore the equation of time is equal to "the difference of the sun's true right ascension, and his mean longitude corrected by the equation of the equinoxes in right ascension."

When  $A m$  is less than  $A v$ , mean or true time precedes apparent; when it is greater, apparent time precedes mean: that is, when the sun's true right ascension is greater than his mean longitude, corrected as above shewn, we must add the equation of time to the apparent to obtain the mean time; and when it is less we must subtract. To convert mean time into apparent, we must subtract in the former case, and add in the latter.

Tables of the equation of time are computed by this rule for the use of astronomers; they are either calculated for the noon of each day, as given in the Nautical and some other Almanacs, or for every degree of the sun's place in the ecliptic, as is done in the annexed tables.

# EQUATION.

EQUATION, *lunar and solar*, in *Chronology*. See METEMPTOSIS.

EQUATOR, or ÆQUATOR, in *Astronomy and Geography*, a great circle of the sphere, equally distant from the two poles of the world, or having the same poles with those of the world.

Such is the circle D A (*Plate XII. Astron. fig. 109.*) its poles being P and Q. It is called the equator, because when the sun is in it the days and nights are equal; whence also it is called the *equinoctial*; and when drawn on maps and planispheres, the *equinoctial line*, or simply the *line*. Every point of the equator is a quadrant's distance from the poles of the world; whence it follows, that the equator divides the sphere into two hemispheres, in one of which is the northern, and in the other the southern pole.

By the passages or transits of arcs of the equator over the meridian, equal or mean time is estimated; hence we have frequent occasion for the conversion of degrees of the equator into time; and again, for the re-conversion of parts of time into degrees or parts of the equator.

For the performance whereof, we subjoin the following table; wherein are exhibited the arcs of the equator, which pass the meridian in the several hours, minutes, &c. of equated or mean time.

Conversion of the Parts of the Equator into Time, and vice versa.

Deg. of Equat.	Hours.	Min.	Hours.	Deg. of Equat.	Hour.	Deg. of Equat.
Min.	Min.	Sec.	Min.	Min.	Sec.	Min.
Sec.	Sec.	Third	Sec.	Sec.	Third.	Sec.
Third.	Third.	Fourth.	Th. "	Th. "	Fourth.	Th. "
1	0	4	1	15	1	0
2	0	8	2	30	2	0
3	0	12	3	45	3	0
4	0	16	4	60	4	1
5	0	20	5	75	5	1
10	0	40	6	90	6	1
15	1	0	9	135	10	2
30	2	0	12	180	20	5
60	4	0	15	225	30	7
90	6	0	18	270	40	10
180	12	0	24	360	60	15
360	24	0	24	360	60	15

The construction of this table is very easy; for the equator being divided into 360 degrees, and revolving always in 24 hours, any point of it moves through 15° in one hour, and in one minute through the 60th part of 15°, or 15' of a degree, and in one second through 15'' of a degree, &c. and therefore nothing more is necessary besides simple addition, in order to have the number of degrees, minutes, and seconds, which it describes in any given time.

The use of the table is obvious; suppose, *e. gr.* it were required to turn 19° 13' 7'' of the equator into time: against 15 deg. in the first column we have 1' 0' 00''; against 4 deg. we have 16' 0''; against 10 minutes, 40''; against 3 minutes, 12'' 0''; against 5 seconds, we have 0' 20''; and against 2 seconds, 8''; which, added together, give 1<sup>h</sup> 16' 52'' 28'''.

Again, suppose it were required to find how many degrees, minutes, &c. of the equator answer to 2½ hours

25 min. 17 sec. and 9 thirds. Against 21<sup>h</sup> in the fourth column of the table, you have 315; and against 2 hours, 30; against 20', 5'; against 5', 15'; against 10 sec. 2' 30''; against 5 sec. 1' 15'' 0''' ; against 2 sec. 30'' 0''' ; against 6 thirds, 1' 30''' ; and against 3 thirds, 45''' ; which, added together, give 351' 19' 17'' 15''' . See EQUINOCTIAL.

EQUATOR, *elevation or altitude of the*. See ELEVATION of the equator.

EQUATOR of the Sun, or Solar Equator. The sun revolves from east to west on an axis inclined to the ecliptic, and the plane, passing through the centre of the sun perpendicular to this axis, is called the plane of the sun's equator. It cuts the plane of the ecliptic in a straight line, called the line of the nodes of this equator; and the nodes themselves are the points where this line, produced each way, meets the celestial sphere.

To determine the position of the axis of rotation in space, it is necessary to determine the inclination of the solar equator to the ecliptic, and the angle which the line of nodes makes with some fixed line in the plane of the ecliptic, for example, with the line of the equinoxes. This angle is called the longitude of the nodes of the solar equator, and is thus determined: when the position of a spot on the disc of the sun has been observed, and its latitude and longitude determined, the direction of the visual rays drawn to the spot at the moment of observation is known. The longitude of the sun at the same instant is likewise known, its distance from the earth, and its apparent diameter.

The intersection, therefore, of its surface with this ray, is found by a simple geometrical process. Three similar observations of the same spot determine three points upon the surface of the sun, and these three spots are situated on the same circumference of some circle parallel to the solar equator, and the position of a plane is known when it passes through three given points. The plane of this circle described by the spot will, therefore, be known by these observations, by which the position of the solar equator may be determined.

To determine the successive positions of the spots on the surface of the sun, supposed spherical, we may imagine the three rectangular co-ordinates or axes passing through the centre of the sun, and continuing parallel to each other during the whole annual revolution. The first of these axes is perpendicular to the ecliptic, the two others are situated in this plane, one parallel to the line of the equinoxes, the other perpendicular to it. Latitudes and longitudes, reckoned relative to these axes from the centre of the sun, are called heliocentric, and they may evidently be found by trigonometric methods, if we can determine their analogous longitudes and latitudes measured in the same manner from the centre of the earth, and which are called geocentric.

By methods of this kind it has been found that the solar equator is inclined to the ecliptic about 7°. It continues constantly parallel to itself, the points of this equator, as they are raised by the rotatory motion of the sun above the plane of the ecliptic, traverse this plane in a point which, seen from the centre of the sun, was, in 1750, 85'. This was then the heliocentric longitude of the solar equator. Since that time it has undergone no variation except what arises from the motion of the equinoctial points.

EQUATORIAL INSTRUMENT, is an instrument made use of in *Practical Astronomy*. When a simple telescope, mounted on a stand, is elevated to view any heavenly body at the moment of its meridian passage, the observed body appears to pass horizontally across the field of view, but in

## EQUATORIAL.

any other situation to the east or west of the meridian, the apparent passage of any heavenly body through the field of view, is in an oblique direction, and the more so, the greater the declination towards the visible pole, and also the greater the distance from the meridian line. Hence the motion of the simple telescope, which moves in a parallel of altitude, or circle parallel to the horizon, when turned round in a state of elevation on its vertical axis, will never coincide with the motion of a heavenly body, that moves either in the equator, or in a circle parallel to it; unless indeed the observer could stand at one of the poles, in which case the equator would become the horizon, and circles of altitude would be also circles of declination. But no observer can be so circumstanced. He may, however, incline the axis of motion of his telescope, so as to be placed in the meridian, and exactly parallel to the earth's axis, and then, when the field of view is directed to take in any heavenly body, the motion of such inclined axis, or the motion of the telescope round such axis, supposing the axis to be fixed, will attend the said body during the remainder of its path above the horizon: Accordingly we find Christopher Scheiner using a telescope mounted on a polar axis in the year 1620, which time was soon after Galileo had invented the simple dioptric telescope, and though John Muller, or Regiomontanus, had contrived and described his torquet, a kind of portable equatorial, in the year 1544, and also Tycho Brahe had given the name of *equatorie* to some of his instruments about thirty years afterwards, yet the idea of Scheiner's polar axis no doubt suggested to the modern instrument-makers the best principle on which an equatorial instrument, as well as equatorial sector, and equatorial stands, ought to be constructed. Scheiner's contrivance was competent to the following of a star or other heavenly body through its diurnal arc, but had no appendages by which to ascertain the place of the observed body, as to right ascension, declination, distance from the meridian, &c. neither would the telescope be directed to a body invisible to the naked eye for want of such appendages.

Mr. Henry Hindley, an eminent clock-maker at York, was probably the first man who contrived and attached the different adjustable circles as companions to the telescope. Mr. Smeaton, in his paper on the "Graduation of Astronomical Instruments," read before the Royal Society of London, on November 17, 1785, has informed us, that Hindley contrived an instrument of the equatorial kind so early as the year 1741, which was sent up to London to be sold in the year 1748. This instrument had the equatorial plate, quadrant of latitude, and declination semi-circle indented at the circumference, and moved by worm-screws, containing fifteen threads each, all in action together, which screws at the same time measured as micrometer screws, the angular motions, and, as it seems, without other graduations. The telescope was of the refracting kind, and inverted the object viewed. "It staid with me," says Mr. Smeaton, "two years, in which time I shewed it to all my mechanical and philosophical friends, amongst whom was Mr. Short, who afterwards published, in the Philosophical Transactions, an account of a portable observatory, but without claiming any particular merit from the contrivance. However, the model of it differs from Hindley's equatorial only in the following articles: he added an azimuth circle and compass at the bottom; he omitted the endless screws, placing verniers in their stead, and at the top a reflecting telescope instead of a refractor. This instrument of Hindley's being afterwards returned to him unfold, I pointed out the principal deficiencies that I found therein; viz. that in putting the instrument into different positions, the spring-

ing of the materials was such, as in some positions to amount to considerable errors. This remained with him in the same state till the year of the first transit of Venus in 1761, when it was sold to — Constable, esq. of Burton Constable in Holderness. Mr. Hindley, to remedy the evil above-mentioned, applied balances to the different movements. He soon after completed one, *de novo*, upon this improved plan, for his Grace the late duke of Norfolk." The next, in point of time, to Mr. Hindley, was Mr. Short, who placed his reflecting telescope over a system of graduated circles, and who has generally been considered as the first contriver of the equatorial instrument, though it appears evident from Mr. Smeaton's account, that Hindley's instrument was prior to his. Mr. Short published his account in the Transactions of the Royal Society, not in the year 1789, as stated by a typographical error under our article CIRCLE, but in 1749, in vol. xvi. N<sup>o</sup> 493. About the year 1770 a rage for making equatorial instruments generally prevailed, and numberless were the modifications that makers of every description produced, but the chief improvers of the instrument at that period were Nairne, Ramsden, and Dollond, who married Ramsden's sister, all of whom, soon after the year just specified, improved on the original portable instrument, chiefly by introducing the improved dioptric in place of the heavy catoptric telescopes, and by using the best divided circles, together with the most accurate adjustments, balancing of the parts, and nicely divided verniers. Mr. Ramsden, to secure the advantages of his share of the improvements, took out a patent for his instrument, including the refraction apparatus, and hanging level in the year 1775.

Still, however, the equatorial instrument had its scale of magnitude adapted only for portability, and its circles consequently were not capable of measuring with that degree of accuracy that celestial observations demand, to be of real use in the present improved state of astronomy; and it remained for Mr. Edward Troughton to construct an equatorial instrument sufficiently large to be placed in an observatory, for the purpose of making useful observations. This ingenious artist contrived many commodious modifications of the instrument under our present consideration, but we mean to confine our notice to two of the principal of them, both worthy of future imitation; one as a moveable, though not very portable instrument, and the other as a fixed one. The first was made to go to Coimbra, in Portugal, where it has had the ill fate to be shut up in the dark, though it was finished so long ago as the year 1788; the latter is now in use under the direction of Dr. Hamilton, at Armagh, in Ireland, and is that with which the Armagh observations were made; of these Mr. Pond, the lecturer on astronomy at the Royal Institution, availed himself when he composed his famous catalogue of declinations of some of the principal stars, which we noticed under our article CIRCLE, and which is inserted in the article DECLINATION. This instrument was made in the year 1796; about three-years after sir George Shuckburgh's large equatorial instrument was described in the Philosophical Transactions of London, as an instrument on a large scale, carefully made under Mr. Ramsden's direction by Mr. Berge, who has since become his successor. The principal modern authors who have described the different equatorial instruments, are Mr. Short, Mr. Benjamin Martin, Mr. Nairne, Mr. Dollond, the Hon. Stuart M<sup>c</sup>Kenzie, professor Vince, and sir George Shuckburgh; at one time it was our intention to describe one or two only of the different constructions of this instrument, and to have noticed the differences of the others; but to do justice to the subject, and to show more clearly the progressive

## EQUATORIAL.

progressive improvements in the art of constructing astronomical instruments of this description, we have determined to give drawings and corresponding descriptions, in succession, of each instrument that appears to possess any claim to originality. Of course we must avail ourselves of the respective descriptions that have been published of the various instruments that have been before described, but our detail will be a condensed one, and interspersed with original remarks, tending to assist the reader in forming his opinion of their respective merits; and where no description has been previously given, as is the case with Mr. Troughton's instruments, and a neat portable one by his nephew, Mr. Farer, we shall supply the accounts from original and authentic sources, preserving, as we proceed, that order of time in which the several instruments were constructed, except in the instance of Mr. Farer's, which being portable, we have thought it better to place immediately after the portable ones of older date, by way of contrast, than to give it a place after the larger and more complete instruments.

*Portable Equatorial Instrument by Mr. James Short.*—We have already said that Mr. Short's equatorial instrument, called by him the equatorial telescope, or portable observatory, was the first instrument probably made in England that could be considered as a well arranged assemblage of graduated circles for ascertaining the various data of a heavenly body's place, out of the meridian, by a single observation. Mr. Ben. Martin has given a brief description of this instrument, together with its uses, in appendix II. of his *Philosophia Britannica*, the substance of which, not being in every one's hands, we think may be acceptable to our readers, particularly as its perusal will afford the best means of contrasting the more improved instruments with the original model, and, consequently, of tracing the progress that the art of making instruments of this kind has made within the period of our own recollection. *Fig. 1. of Plate XI. of Astronomical Instruments*, exhibits a perspective view of all the essential parts of Mr. Short's instrument, which is composed of four graduated circles, two of them entire, and two of them about three-fourths of a circle, together with a four-footed stand, a variety of supporting pillars, levels, wheels, and endless screws, axes of motion, and a reflecting telescope surmounted over the whole. A, A, are two horizontal plates one over the other, and representing the horizon of the place of observation; these plates rest on four pillars of the pedestal, that contains a magnetic box and needle, and that is supported by the four adjustment screws B, B, B, B, the lower plate being fast to the pillars, and the upper one, that carries two spirit levels on its plane at right angles to each other, being moveable by a rod or handle C, the screw on which takes into the teeth cut on the edge of this upper horizontal plate. This moveable plate is divided into  $360^\circ$ , and a vernier borne by the under plate reads to the accuracy of every three minutes. Another set of four pillars, inserted into the moveable horizontal plate, supports the vertical circle D D, or rather portion of a circle, which is divided into twice  $90^\circ$ , and somewhat more at each side, and is called the meridian circle; its vernier, placed on the upper horizontal circle, reads also every three minutes of space. The handle or rod E moves this circle in like manner as the rod C moves the horizontal circle described. On the upper or mutilated part of the meridian circle D D, are placed two other plates, the upper one moveable on the under one, like the horizontal plates, and the vernier carried by the under one. It does not appear from the drawing or account whether the axis of motion rotates or is fixed. The upper or moveable plate, marked F F, is divided into hours and ten-minute spaces, and these again are subdivided

by the vernier into single minutes of time. This plate, which is called the equatorial plate, has a third set of pillars inserted into it, and is moveable by the rod G, like the other moveable plates; the pillars support a fourth circle, or rather mutilated circle H H, on the upper part of which the telescope L L is mounted, as seen in the drawing. This uppermost circle is called the circle of declination or horary circle, and is divided into twice  $90^\circ$ ; it is also moveable by the rod or handle K, like the rest of the moveable circles; and has every three minutes of space, by its vernier, placed on the plane of the equatorial circle. The telescope is of the Gregorian construction, with a great speculum of 18 inches focal length. In making the adjustments of this instrument for observation, the horizontal plates A, A, are first levelled by the joint aid of the two levels and screws of adjustment that bear the whole fabric; this adjustment is not perfect till the bubbles of the levels will remain stationary, in the middle of their tube, while the upper plate is carried quite round the subjacent one. In the next place the meridian circle D D is turned by its handle E, till the equatorial plates are parallel to the equator; that is, till they are raised equal to the complement of the latitude of the place of observation, and the instrument is said to be fit for making observations; of course the placing of the circles relatively to each other, in regard to perpendicularity, and of the line of collimation of the telescope in regard to the points zero in the declination circle, are supposed to be immoveably adjusted by the maker, so as to require no future rectification. As it will be of some importance to the development of the progressive improvements of the different equatorial instruments, to confine ourselves to the uses that this instrument by Mr. Short was applied to, we cannot do better than confine ourselves to the words of one of the early descriptions of its practical application.

*“To find the Hour of the Day, and Meridian of the Place.*—First, find, from astronomical tables, the sun's declination for the day, and for that particular time of the day; then set the declination-semicircle to the declination of the sun, taking particular notice whether it is north or south, and set the declination-semicircle accordingly.

“You then turn about the horizontal handle, and the equatorial handle, both at the same time, till you find the sun precisely concentrical with the field of the telescope. If you have a clock or watch at hand, mark the instant of time; and by looking upon the equatorial plate and vernier, you will find the hour and minute of the day, which comparing with the time shewn by the clock or watch, shews how much either of them differs from the sun. In this manner you find the hour of the day.

“Now, in order to find the meridian of the place, and, consequently, to have a mark by which you may always know your meridian again, you first move the equatorial plate, by means of the equatorial handle, till the meridian of the plate or hour-line of 12 is in the middle of the vernier; and then, by turning about the declination-handle till the telescope comes down to the horizon, you observe the place or point which is then in the middle of the field of the telescope; and a supposed line, drawn from the centre of this field to that point in the horizon, is your meridian line. The best time of the day for making this observation for finding your meridian is about three hours before noon, or as much after noon. The meridian of the place may be found by this method so exact, that it will not differ at any time from the true meridian above  $10''$  of time, and if a proper allowance be made for the refraction at the time of observation, it may be found much more exact. This line

## EQUATORIAL.

line thus found will be of use to save trouble afterwards; and is, indeed, the foundation of all astronomical observations.

*To find a Star or Planet in the Day-Time, even at Noon-Day.*—The instrument remaining as rectified in the last experiment, you set the declination-semicircle to the declination of the star or planet you want to see; and then you set the equatorial plate to the right ascension of the star or planet at that time, and, looking through the telescope, you will see the star or planet; and after you have once got it into the field, you cannot lose it: for, as the diurnal motion of a star is parallel to the equator, by your moving the equatorial handle so as to follow it, you will at any time, while it is above the horizon, recover it, if it be gone out of the field.

“The easiest method for seeing a star or planet in the day-time is this; your instrument being adjusted as before directed, you bring the telescope down so as to look directly at your meridian mark; and then you set it to the declination, and right ascension, as before-mentioned.

“By this instrument most of the stars of the first and second magnitude have been seen even at mid-day, and the sun shining bright; as also Mercury, Venus, and Jupiter: Saturn, and Mars are not so easy to be seen, upon account of the faintness of their light, except indeed when the sun is but a few hours above the horizon.

“And in the same manner in the night-time, when you can see a star, planet, or any new phenomenon, such as a comet, you may find its declination and right ascension immediately, by turning about the equatorial handle, and declination handle, till you see the star, planet, or phenomenon; and then looking upon the equatorial plate, you find its right ascension in time; and you find upon the declination-semicircle its declination in degrees and minutes.

“In order to have the other uses of this instrument, you must make the equatorial plates become parallel to the horizontal plates; and then this instrument becomes an equal altitude instrument, a transit instrument, a theodolite, a quadrant, an azimuth instrument, and a level. The manner of applying it to these different purposes is too obvious to need any explanation.

“As there is also a box with a magnetic needle fastened in the lower plate of this instrument, by it you may adjust the instrument nearly in the meridian; and by it likewise you may find the variation of the needle; if you set the horizontal meridian, and the equatorial meridian, in the middle of their verniers, and direct your telescope to your meridian mark, you observe how many degrees from the meridian of the box the needle points at: and this distance or difference is the variation of the needle.”

These are the uses to which Mr. Short's instrument, before us, was principally applied, and had the circles been divided with verniers subdividing the divisions more minutely, it would have been something more than an astronomical play-thing, to which it cannot be considered as any thing superior, when it comes to be contrasted with one of the most improved kind, even of those that are equally portable. We cannot dismiss our notice, however, of the present instrument, without remarking further, that the manner in which the two pairs of plates A A, and F F, move over each other respectively, is by no means calculated to preserve a steady undeviating motion, for want of a sufficient length in the axis of motion. This is the principal objection we expressed to Dr. Wollaston's circle made by Mr. Cary, and if the doctor borrowed his notion of such a position of his circles from Mr. Short, he copied one of the worst properties that this artist's instrument possesses.

This equatorial instrument has obtained the name of

universal, from the circumstance of its being applicable to use in any latitude; which name is equally due to its successions.

*Portable Equatorial Instrument by Mr. Ed. Nairne.*—The imperfections of the preceding instrument were attempted to be removed by Mr. Nairne, whose construction introduced a long axis of motion for the horizontal circle, thereby effecting a steadiness in its performance, and placed the telescope on the axis of the declination-semicircle to obtain a less encumbered elevation of the telescope; but still the circles were not graduated so minutely as to render them of real use in practical astronomy. A brief account of this instrument is contained in vol. lxi. part i. of the Philosophical Transactions of London, and was read before the Society on Feb. 7, 1771. Its substance is this:—

The instrument consists of the following parts, *Plate XII. fig. 1. of Astronomical Instruments*, a mahogany triangular stand A A A, and three adjusting screws B, B, B, a moveable azimuth circle C, which is divided into degrees, and by a vernier index into every six minutes; above this azimuth circle is the horizontal plate D, to the under part of which is fastened the vertical conical axis E; on the middle of the upper surface of the horizontal plate is placed a ground glass level F, by which the plate D is set parallel, and the pillar E perpendicular to the horizon; from this plate rise perpendicularly two quadrants G, G, one of which is divided for the latitude into half degrees, and has a vernier index to three minutes; the equatorial plate H, with its hour circle, is supported by the two quadrants G, G, its axis of motion, which is placed near the hours XII, XII, passes through the centres of the quadrants, and carries the index I, pointing to the divided quadrant; the equatorial plate is divided into half degrees, and has a vernier index shewing every three minutes of right ascension, or 12 seconds of time; it is figured to shew both degrees and time. To prevent misapprehension it may be right to remark that the hours XII, XII, ought properly to have been placed according to the meridian line; but they are here placed otherwise for the convenience of better seeing the meridian distance shewn by the vernier. On the upper part of the equatorial plate is the plate K; upon this plate K are fixed the two supporters M, M, which support the axis N, under which is fastened the semicircle of declination O, divided into half degrees with a vernier subdividing it into every three minutes. On the upper part of this axis is fixed an achromatic telescope P, which magnifies about 50 times; to the eye-end of this telescope is applied a small reflecting speculum, making an angle of 45° with the axis of the telescope, whereby objects that are in the zenith or in any other altitude may be observed without putting the body in an inconvenient position. To the under part of the axis N is fastened a brass arm carrying the weight Q, which counterbalances the telescope, and brass-work annexed to it; whilst the weights R, R, counterbalance in like manner the whole of the instrument that is moveable on the equatorial axis, so that whatever position the instrument is put in it will there remain, being perfectly balanced. The four motions of this instrument may, when required, be moved extremely slowly, by means of the indented edges of the circles and semicircles, and the screws or worms of the handles S, T, V, and W, for the horizontal circle, the motion for latitude, the equatorial and declination motions respectively. The adjustments and uses of this instrument are so similar to those of its predecessor, both in kind and extent, that it would be superfluous to particularize them again. In this account it is not stated whether the axis of motion of the equatorial circle is prolonged,

## EQUATORIAL.

longed, but as the height to which it is elevated above the horizon circle seems to admit of it, and as the axis of this is elongated, we are disposed to believe that a similar advantage belonged to the former; otherwise it would not have that stability that is necessary in this part of the instrument for making the most essential motion steady enough to be depended on. How far the mahogany legs were firm and steady enough for the purpose of affording a motionless pedestal is not said; but the want of accuracy, or rather the want of minuteness in the divisions and subdivisions of the graduated circles, quadrant, and semicircle, made this consideration of less importance than it would have been in an instrument possessing greater powers. We have been informed, from credible authority, that Mr. W. Ludlam, of St. John's college, Cambridge, was the principal contriver of Mr. Nairne's construction.

*Ramden's portable equatorial instrument.*—The principal parts of this instrument, says professor Vince, (Treatise on Prac. Astr.) are, the azimuth circle *GH*, the equatorial, or hour circle *EF*, and the declination circle *CD*; (see *Plate XI. fig. 2. of Astronomical Instruments*;) to this latter there is fixed a telescope *AB*, having under it a rod *mn*, passing through two pieces  $\pi$ ,  $\rho$ , in one of which, as  $\pi$ , are two screws acting on the rod against each other, in order to adjust the rod perpendicular to the axis on which the declination circle turns. The azimuth circle *GH* lies on a brass plate *tu*, supported by three feet, resting on the screws *X, Y, Z*, and on this plate it turns about an axis *T*, by means of a screw *S*; upon this circle are placed two spirit levels *c d, a b*, at right angles to each other, supported at each end by a screw, by which they may be adjusted; the circle is divided into twice  $180^\circ$ , and has a vernier *V* fixed on the plate *tu*, by which the degrees are subdivided into minutes or half minutes, according to the size of the instrument; and by means of the screw *I* the circle may be fixed to the plate *tu*. *KK* is a polar axis moveable about a centre *L*, sustained by two supporters  $\eta, i$ , resting on two pieces *W, V*, firmly connected to the plane of the circle *GH*; the lower end of this axis has an arc fixed to it, which runs against an arc  $\alpha\gamma$ , attached to *GH*, and to which it may be fixed by a key at *e*; and in this situation, if you apply the key to *Q*, it gives a motion to the axis, by which you may very accurately adjust the telescope to an object. To the centre *L*, and perpendicular to the polar axis, are fixed two strong pieces of brass, one of which is here represented by  $\kappa$ , and the other is on the other side of the axis; these support a circle  $\alpha\beta\gamma\delta$ ; on the top of the polar axis, and perpendicular to it, is placed a brass plate, moveable about a pivot on the top of the axis; to this are fixed four pieces, two of which are represented by  $f, g$ ; these are connected to the hour circle *EF*, lying on  $\alpha\beta\gamma\delta$ , and carry it about; upon  $\alpha\beta\gamma\delta$ , at *W*, is fixed a vernier to the circle *EF*, which circle is divided into twice twelve hours. The declination circle *CD* is supported by its centre, on an axis resting on two supporters  $h, k$ , on one side, and two others of the like kind on the other; these rest upon the brass piece on the top of the polar axis, and may be adjusted by two pair of screws at the feet of the two supporters, to set the plane of the declination circle perpendicular to the hour circle, which, by the maker, is placed perpendicular to the polar axis. This circle is divided from zero both ways to a little more than  $90^\circ$ , and a vernier is placed at *R* to subdivide, as at *V*. A small quadrant is fixed to the eye-piece of the telescope, which turns round upon the piece, carrying two wires perpendicular to each other, for the parallel of declination and hour circle. The eye-piece carries two cross

wires to represent the circle of altitude and a parallel to the horizon. The quadrant has two radii  $o$ , perpendicular to each other, and move together; the former has a round or circular spirit level upon it, so that by turning about the eye-glass and the quadrant till the bubble rests in the middle, the plane of the quadrant becomes perpendicular to the horizon; and the vernier on the latter shews the altitude to which the telescope is directed, and the corresponding refraction; and in this position the circle of altitude is perpendicular to the horizon. At *P* is a small micrometer circle, called the refraction circle, (with a fixed index,) moveable by a finger screw; this circle is divided into half minutes, and one revolution is equal to  $3' 18''$ ; when moved it raises or depresses the centre of the cross wires in a circle of altitude.

After this general description of the parts of the instrument, let us consider what motions it is capable of, and what the circles may be made to represent, before we proceed to its adjustments. And first, the azimuth circle *GH*, being set parallel to the horizon, will represent the horizon; secondly, if the polar axis *KK* be inclined to the horizon at an angle equal to the latitude of the place, the equatorial circle *EF* will be inclined to the horizon in an angle equal to the inclination of the equator to the horizon; therefore, if we turn about the azimuth circle, and consequently the equatorial circle, the latter may be made to coincide with the equator; thirdly, if the declination circle be set perpendicular to the equatorial, then the consequences must be, that if the line of collimation be adjusted parallel to the plane of the declination circle, or perpendicular to its axis, and also parallel to the equatorial circle *EF*, when zero on the declination circle coincides with zero on the vernier *R*, then the telescope is directed to the equator in the heavens, and by turning about the declination circle the line of collimation will describe a secondary to the equator; and by setting the declination circle to the declination of any body in the heavens, if we turn about the circle *EF*, and consequently the circle *CD* with the telescope, on the brass plate, on the top of the polar axis (which is kept fixed,) the equatorial circle, moving in its own plane perpendicular to the polar axis, must continue to coincide with the equator, and, consequently, the telescope will describe a parallel to the equator, and therefore must bring the body into the field of view. These being the motions of the parts of the instrument, we may now proceed to describe the necessary adjustments for them.

*Adjustments.*—1. *To adjust the azimuth circle parallel to the horizon.*—Turn it till one of its levels becomes parallel to a line joining two of the screws at the feet, as *X, Z*, and then adjust that level with one of them; turn the circle half round, and if the bubble be not in the middle, adjust it half way, by one of the above-mentioned screws, and half way by the screw at one end of the level; repeat this operation till the bubble stands right in both these positions; then turn the circle at right angles to these positions, and, if necessary, set the bubble right by the other screw *Y* at the foot, and the adjustment is made. If you previously adjust the other level by one of the screws at the end, then the circle may be adjusted horizontal by them, without turning it.

2. *To adjust the level  $rs$  parallel to the rod *mn*.*—Set the polar axis, as near as you can, perpendicular to the horizon, and turn about the declination circle *CD* by a pinion for that purpose, until the bubble of the level *rs* stands in the middle; reverse the level, and if the bubble do not stand in the middle, adjust it half way by the screw at *S*, under

## EQUATORIAL.

one end of the level, and half way by turning the declination circle; and repeat the operation till the bubble stands in the middle in both positions.

3. *To adjust the rod  $m n$  perpendicular to the axis on which the declination circle turns.*—Set the polar axis as near as you can parallel, and consequently the equatorial circle perpendicular to the horizon; set the declination circle to zero, and turn the hour circle till the bubble stands right; then set the declination circle to  $90^\circ$ , and adjust the bubble by the polar axis: then turn the declination circle to the opposite  $90^\circ$ , and if the level be not right, correct half the error by the polar axis, and the other half by the two screws in the piece  $\alpha$ , releasing one and screwing up the other; repeat this operation till the bubble stands right in both positions, and the adjustment is made. For these two adjustments tend, the former to set the axis of the declination circle, on the axis about which the rod revolves, perpendicular to the horizon: and the other to set the rod  $m n$  parallel to the horizon, and consequently perpendicular to that axis; when, therefore, the bubble thus continues right, both circumstances must have taken place.

4. *To set the axis of the declination circle perpendicular to the polar axis.*—The instrument remaining as in the last adjustment, that is, the declination circle at  $90^\circ$  and the bubble right, turn the equatorial circle half round, and if the bubble be not right, correct half the error by the polar axis, and the other half by the two pair of screws at the feet of the two supporters  $b, k$ ; and repeat this operation till the bubble is right in both positions, and the adjustment is completed. For the former adjustment tends to set the axis of the declination circle perpendicular to the horizon, and the latter to set it parallel to the equatorial circle, or perpendicular to the polar axis; consequently, when the bubble is right in both the above positions both circumstances must take place, that is, the polar axis must be parallel to the horizon, and the axis of the declination circle perpendicular to it. And as this adjustment is made by the level, which is horizontal when the axis of the declination circle is thus adjusted perpendicular to the horizon, and which is previously adjusted parallel to the rod, they must both be perpendicular to the axis, about which they turn; and, consequently, they move in a plane passing through the polar axis, or perpendicular to the equatorial circle. Hence, also, the declination circle, being perpendicular to its own axis, becomes perpendicular to the equatorial circle.

5. *To make the centre of the cross wires cut the same object whilst you turn round the eye-glass by the pinion of the refraction apparatus.*—Set the index on the refraction circle to the beginning of the divisions, and turn round the eye-glass, and if the centre of the wires do not continue to cut the same object, correct it by four small screws (which you will find by unscrewing the nearest end of the eye-tube which contains the first eye-glass), the two opposite at a time, and repeat the correction till the centre continues to cut the same object.

6. *To make the line of collimation describe a great circle perpendicular to the equatorial circle.*—Set the declination circle to  $90^\circ$ , and the equatorial circle to VI, and bring the bubble to the middle by the polar axis. Then note some object covered by the centre of the cross wires, representing the parallel of declination and hour circle, and turn the equatorial circle half round, and if the same object be not now covered by the centre of the wires, move, if necessary, the declination circle in its own plane, until it is in the same vertical circle with the object, and then bring the centre half way to it by the upper and lower of the four small

screws which move these wires, and turn the declination circle back through half the space it was moved, and you get a new object now covered by the centre of the wires; repeat this operation till the same object be covered in both these positions; then set the hour circle to XII, and bring the bubble to the middle by the declination circle, and if the centre do not now cover the same object, bring it to the object by the other two screws, and the line of collimation is adjusted parallel to the level, or to the rod  $m n$ , and, consequently, it must be perpendicular to the axis of the declination circle. Hence as that circle is turned about in its own place, the line of collimation must describe a secondary to the equator. The line of collimation for the centre of the cross wires being thus adjusted, it is, at the same time, in the centre of motion, on which the wires parallel and perpendicular to the horizon turn; hence, when the index of the refraction circle is set to the beginning of the divisions, the interfections of the two sets of wires coincide. The adjustment of the wire parallel to the equatorial circle may be examined by the passage of a star through the telescope, (all the other adjustments being previously made, and the equatorial circle adjusted to coincide with the equator in the heavens, and the declination circle set to the star's declination;) for if the star do not run upon the wire, it must be adjusted till it does: or it may be done thus. Set the equatorial circle to XII, and having directed the line of collimation to some small well defined object, turn the declination circle in its own plane, and observe whether the perpendicular wire continue to cut the same object as it passes through the field of view; if not, adjust till it does.

7. *To adjust the verniers of the equatorial and declination circles.*—Elevate the equatorial circle to an angle of about  $45^\circ$ , as most proper for this purpose, and set the declination circle to zero, and turn the equatorial circle in its own plane till the bubble stands right; then turn the equatorial circle half round, and if the bubble do not stand right, adjust half by moving the equatorial, and half by moving the declination circle; and repeat this operation till the bubble stands right in both positions, then, by moving the verniers, set zero on the vernier belonging to the equatorial circle to VI, and zero on the vernier belonging to the declination circle to zero, and the verniers are adjusted. Thus the instrument is ready for observation, except that the azimuth circle is not adjusted to shew azimuths, which will be done when we come to shew the methods of making observations.

The method here used arises out of the two distinguishing features of the instrument under our consideration; namely, the position of the level near the telescope, and the want of graduations on the latitude arch, or arch for giving the polar axis its due inclination.

But the Hon. Mr. M'Kenzie's method appears to us more simple, as well as more intelligible, for elevating the equatorial circle to the co-latitude of the place, thus; "lower the telescope as many degrees, minutes, and seconds below zero, on the declination-semicircle, as the complement of your latitude is; then elevate the polar axis till the bubble be horizontal, and the equatorial circle will be elevated to the co-latitude of the place, as required; after which the level may be made to stand true in opposite positions, and the verniers be placed to zero, as above directed.

Mr. Atwood, in his Syllabus, has given another method of making this adjustment, which professor Vince acknowledges to have the advantage over his in point of both ease and accuracy, the substance of which is as follows:

## EQUATORIAL.

Having set the declination circle to  $90^\circ$  in either quadrant, direct the point of intersection of the cross-wires to coincide with some distant object as a mark; turn the equatorial circle in its own plane  $180^\circ$ , and if the intersection does not now coincide with the distant mark, correct half the error in declination by moving the declination circle in its own plane, and half the error in right ascension by the set screws of the supporters that adjust the axis of the declination circle; now if these adjustments be accurately made, the intersection will coincide with any distant mark, chosen anew, when the equatorial circle has been turned  $180^\circ$ ; but if the coincidence is not perfect, the same adjustments must be repeated till the condition is fulfilled. The line of collimation being now directed to coincide with the distant mark, set the vernier of the declination circle to  $90^\circ$ , and turn this circle  $180^\circ$  in its own plane, turn also the azimuth circle, so that the line of collimation may be again directed to the said distant mark, then turn the equatorial circle about in its own plane  $180^\circ$ , and if the distant mark be not now covered by the intersection, the quantity of deviation shews double the total error of dividing the two semi-circles of the declination circle, and also its eccentricity, which errors cannot be allowed for by adjustment. The error in right ascension, now discovered, must arise from the plane of the declination circle not being quite perpendicular to the equatorial, and also from the line of collimation not being exactly parallel to the plane of the declination circle; therefore correct  $\frac{1}{4}$ th of the error by the screws of the declination axis, and  $\frac{1}{4}$ th by moving the line of collimation perpendicular to the plane of the declination circle: if the first trial of these adjustments be not attended with complete success, when the distant mark is again examined in reversed positions they must be repeated till they are correct. Hence it is manifest, when the above adjustments are properly made, 1st, that the line of collimation is parallel to the plane of the declination circle; 2dly, that the plane of the declination circle is perpendicular to the plane of the equatorial; 3dly, that the errors of division are at the opposite points  $90^\circ$ , if any are discovered in the declination circle, and, 4thly, that when the declination circle is set to  $90^\circ$ , the line of collimation is perpendicular to the plane of the equatorial circle, or, when it is set to zero, it is parallel to it.

The azimuth circle being adjusted horizontal, and the declination circle put to  $90^\circ$ , make the vertical wire parallel to it, turning the equatorial and azimuth circles in their respective planes; direct the point of intersection to a distant mark near the horizon, and move the azimuth and declination circles each in their own planes to  $180^\circ$ , so that the said mark may appear somewhere in the vertical wire, and if there is an error in altitude, let the line of collimation bisect it, by moving the polar axis, and it will then be horizontal. Let this new bisected point or mark in the horizon be noted; then the declination circle being put to zero, turn the azimuth circle  $90^\circ$ , so as to bring the new mark upon the cross wire, and direct the intersection to it by turning the equatorial circle in its own plane, and the declination is in that situation parallel to the horizon. The instrument remaining as before, turn the equatorial and azimuth circles in their respective planes  $180^\circ$ , and if each circle be accurately divided, the telescope must evidently be brought into a position exactly parallel to its former one, and therefore the intersection of the wires will again coincide with the new mark in the horizon. Otherwise the quantity each of those circles must be moved further or back, will shew their respective errors of eccentricity and also of division. Lastly, the declination circle being at zero,

and the line of collimation or intersection made to coincide with the horizontal mark, by moving the equatorial and azimuth circles, set the equatorial vernier to VI, and the adjustment is finished; for the line of collimation being parallel to the horizon and to the plane of the declination circle when the vernier stands at VI, that plane, by revolving about the polar axis, must be perpendicular to the horizon when the vernier stands at XII, which is the thing required.

### *Methods of making Observations.*

1. *To take the altitude of a body above the horizon.*—Set XII on the equatorial circle to zero on its vernier, and the plane of the declination circle is then perpendicular to the horizon; make, therefore, the line of collimation horizontal, by bringing the bubble to the middle of the level in the telescope, and observe what point of the declination circle stands against zero in its vernier, and then by moving the declination and azimuth circles in their own planes, bring the body to the centre of the cross wires, and observe again what point of the declination circle stands against zero, and the arc intercepted between these two points gives the apparent altitude. If the declination circle had been set to zero, and the line of collimation been adjusted horizontal by moving the polar axis, then, when the body had been brought to the centre of the cross wires, the declination circle would have shewn its altitude at once. For Mr. Atwood's indirect methods of taking an altitude, see pages 163, 164, and 165 of Vince's "Treatise on Practical Astronomy."

2. *To measure very small vertical angles.*—Let the elevation of the equatorial circle be  $a$ , the polar distance of the telescope (either more or less than  $90^\circ$ ) be  $b$ , and set XII (corresponding to noon) on the equatorial circle to zero; then if that circle describes an angle whose versed sine is  $v$ , and the line of collimation be brought (by moving the azimuth circle) back to the same vertical, it will have been depressed through a vertical arc equal to  $\frac{v \times \text{si. } a \times \text{si. } b}{\text{si. } b - a}$ , radius being unity. Or, if  $b = 90^\circ$ ,

the depression =  $v \times \tan. a$ . Hence if, for example, it should be required to find the angle which the horizontal wire of the telescope subtends, select some well defined distant object, set the declination circle to zero, and XII on the equatorial to zero, and elevate the equatorial so as to bring the object into the field of view, and make the upper edge of the wire coincide with it, then move the equatorial and azimuth circles in their own planes till the lower edge coincide with it, and read off the equatorial arc. *Ex.* If the elevation of the equatorial be  $41^\circ 3'$ , and the arc denoted by the equatorial vernier be  $57'$ , the angle required =  $\text{vec. sin. } 57' \times \tan. 41^\circ 3' = 24'' 6''$ . Hence also the diameter of a planet may be measured. When the planet comes to the meridian (the two circles being fixed as before) alter the elevation of the equatorial circle, and bring the upper edge of the horizontal wire to be a tangent to the upper limb of the planet (or the apparent lower limb), and then by turning the azimuth and equatorial circles in their own planes, bring the lower edge of the wire to be a tangent to the lower limb of the planet (or the apparent upper limb), and the rule gives the sum of the diameters of the planet and wire, from which subtract the diameter of the wire, and you get the diameter of the planet.

3. *To find the latitude of a place.*—Take the altitude of the sun's upper or lower limb a little before noon, and continue your observation till he rises no longer, and you get

## EQUATORIAL.

his apparent meridian altitude; with which and his declination you may find the latitude by the common rule.

4. *To incline the equatorial circle so as to make any angle with the horizon.*—Set the declination-circle (in the southern quadrant) to the given angle, and XII on the equatorial circle to zero on its vernier; then bring the line of collimation horizontal by moving the polar axis till the bubble in the level on the telescope stands in the middle, and the equatorial circle stands at the proper angle.

5. *To determine the position of the meridian.*—Elevate by the last article the equatorial circle, to make an angle with the horizon equal to the co-latitude of the place, and set the declination-circle to the declination of any known star, then turn the equatorial and azimuth-circles in their own planes till the star is brought to the centre of the cross wires, and correct the position of these circles on account of refraction, by the small quadrant and apparatus at the eyepiece of the telescope, and the equatorial circle will then coincide with the equator in the heavens, and the vernier will shew how far, in time, the star is from the meridian; and hence, if we turn the equatorial circle till XII stands at zero on the vernier, the plane of the declination-circle will coincide with the meridian. Hence, if we direct the telescope to the horizon, the point which the centre of the wires will cut is the south point of the horizon, and may serve for a meridian mark. If the point of the arc of the azimuth-circle lying against zero on its vernier be noted, the error in its position will be known; and if this be very small, so that by moving the vernier till zero on it may be brought to zero on the arc, it may be adjusted to shew azimuths. The position of the vernier of the azimuth-circle may also be verified thus. The equatorial-circle being set parallel to the horizon, and XII set to zero on its vernier, turn the azimuth-circle, and by moving the declination-circle, bring a star on the east side of the meridian to the centre of the cross wires, and note the azimuth, then turn the azimuth-circle (the telescope remaining fixed) and do the same when the body comes to the west side; and if the azimuths at both observations be the same, the vernier is adjusted right; if not, half their difference is the error. The instrument being set upon a moveable plane, if the points on which the three screws at the feet rest be marked, it will then always be easy to set the azimuth-circle very nearly in its proper position.

6. *To determine the apparent time of the day.*—Proceed as in the last article, only take the sun instead of a star, and bring its centre to the centre of the cross wires, and correct for refraction, and the arc intercepted between XII and zero on the vernier shews the distance of the sun, in time, from the meridian, or from apparent noon.

7. *To find a star or planet in the day-time.*—Elevate the equatorial-circle to make an angle equal to the co-latitude, and adjust it to coincide with the equator in the heavens, and set the declination-circle to the declination of the body. Find by the usual way the distance of the star from the meridian at the time required, and reduce it to sidereal time; then turn the equatorial-circle in its own plane, east or west, as the star lies, till the arc between XII and zero on the vernier be equal to that time, and the star will be in the field of view. By this means Jupiter, Venus, and fixed stars of the first magnitude, may be observed in the day-time.

8. *To find the right ascension and declination of a star.*—Elevate the equatorial-circle to the co-latitude of the place, and previously set it to coincide with the equator in the heavens, and set XII on the equatorial-circle to zero on its vernier. After this set the declination-circle to the sun's declination, and take the time of its transit; then set the

declination-circle to the star's declination and take the time of its transit, and the difference of the times will give the difference of their right ascensions; and the star's transit being taken at the intersection of the wires, the declination-circle (corrected for refraction) will give its declination. Thus also you may compare two stars, or the moon and a star. Or it may be done at any time, if you move the declination and equatorial-circles in their own planes till the star is brought to the centre of the cross wires, and correct the position of these circles on account of refraction, and the declination-circle will give you the declination required; and the vernier of the equatorial-circle will give you the star's distance, in time, from the meridian, or your clock will give you the sun's distance, the difference of which times gives the difference of their right ascensions, and, therefore, knowing the sun's right ascension, you have the right ascension of the star.

9. *To find the longitude.*—The equatorial-circle being set to coincide with the equator in the heavens, and XII to zero on its vernier, take the time of the transit of the moon's limb, and also of a proper star as near as possible to the moon's parallel, and the longitude may be determined therefrom by the lunar method, in the usual way.

10. *To measure horizontal angles.*—Adjust the equatorial-circle parallel to the azimuth-circle; and having directed the line of collimation to one of the objects, move the equatorial-circle in its own plane, and also the declination-circle, if necessary, and bring the line of collimation to the other, and the arc through which the equatorial-circle has moved gives the angle required.

As an appendage to this account, by professor Vince, of Ramsden's portable equatorial instrument, we think it may be acceptable to our readers to have the Hon. S. M'Kenzie's account of Mr. Ramsden's new refraction apparatus much improved, which was published in his anonymous pamphlet, (dated in the year 1791, a year after the professor's treatise was published), together with the explication of the principles on which the apparatus was constructed.—“Refraction or parallax,” says our author, “by changing the apparent altitude of a planet, may also change its apparent right ascension and declination; see fig. 2. of Plate XII. (of *Astron. Instr.*) where HO represents the horizon; EQ, part of the equator; P, the pole of the equator; Z, the zenith; PEH, the meridian; ZV, an arc of a vertical drawn through I, the apparent place, and F, the true place of the planet; PA, a circle of declination, or hour-circle, drawn through the true place F; and PB, a circle of declination or hour-circle drawn through the apparent place I. The error in altitude from F to I alters the right ascension of the planet as much as the arc of the equator AB, or its parallel FC, amounts to. It also alters its declination from AF to BL, that is, from C to I. If a planet be in the meridian at L, the error, in declination from L to K, will be the same as the error in altitude; but there will be no error in right ascension, because the same circle of declination PEH, (perpendicular to the horizon,) passes through the apparent place K, and the true place L. In like manner, if by the construction of an instrument you have a vertical circle ZV, perpendicular to the horizon, it will pass through the apparent place I and the true place F, and there will be no error in right ascension; and if by the same instrument the error in altitude from F to I be determined, the true place F is found, and consequently there will be no error in declination. With Mr. Ramsden's new refraction apparatus you have just such a vertical circle as will appear from what follows.

In the focus of the telescope of the equatorial two *fixed* wires

# EQUATORIAL.

wires are placed at right angles to each other; one, E Q, (see fig. 4.) represents part of a parallel of the equator; the other, P A, part of a meridian, or hour-circle. There are also two moveable cross wires at right angles to each other; one, H O, represents a portion of a parallel to the horizon; the other, Z V, a portion of a vertical circle. These moveable wires have a motion round the axis of the telescope, by turning a pinion.

A small quadrant (see Plate XI. fig. 2. and also Plate XII. fig. 2.) is fixed on the part that carries the moveable wires, with divisions on each side; one expressing the degree of altitude of the object viewed, the other expressing the minutes and seconds of error occasioned by refraction, corresponding to that degree of altitude. To the index of this quadrant is fixed a small circular level, which being adjusted by its own pinion, gives the altitude; while by another pinion it ascertains the perpendicularity of one of the moveable wires, which gives the vertical circle above-mentioned, whereby the true right ascension may be determined, free from all error arising from refraction or parallax. Hence, in taking the moon's right ascension with an equatorial instrument, fitted with this refraction apparatus, in order to determine longitudes at land, there is no occasion to attend to her parallax, as the difference of her right ascension, caused by parallax or refraction, will only depress or elevate her on the same vertical circle, but will not change her right ascension from one hour-circle to another. In this refraction apparatus the centre of the fixed wires always remains in the line of collimation; whereas by the former construction, on raising or depressing that centre, it was moved out of that line; and as it was very difficult to replace it exactly, an error in the observation was liable thereby to be produced. In all observations made with this refraction apparatus, first adjust the circular-level, then set the centre of the moveable wires, by the micrometer screw, to the refraction corresponding to the altitude of the object viewed, as given by the small quadrant; and let one of the moveable wires be set always perpendicular. Since copying the preceding extract from Mr. McKenzie's pamphlet, we have been assured that it was published previously to professor Vince's treatise, and that the date 1791 is a typographical error for 1771; accordingly, we learn from Mr. Dollond, that Ramsden's instrument preceded his, but our inquiries to obtain the *precise time* of its origin have not been successful. The two different sizes of Ramsden's portable instrument were according to the following table of dimensions.

	Rad. in In.	Limb divided to	Vernier of 30 gives	Divided to parts	By vernier into
Azim. or horizontal circle,	5.1	15'	0° 30"	45 <sup>th</sup> of in.	1350 <sup>h</sup>

*Portable Equatorial Instrument by Messrs. P. and J. Dollond.*  
—Mr. Dollond informs us that his father contrived the instrument, which now comes under our notice, in or about the

year 1775, and the readiness with which he communicated all the particulars we wished for respecting it deserves our grateful acknowledgment. This instrument, says the author, (in his quarto pamphlet,) which of all others is the most amusing to lovers of astronomy, is now rendered, by the following improvements, greatly superior to any hitherto produced. As the whole weight does not exceed thirty pounds, it may be said to be truly portable, yet, by the steadiness of all the parts, and the perfection of the achromatic telescope, the observations may be made to a very great exactness. The focal length of the achromatic object-glass is about 17 inches; it is composed of three glasses, and admits of an aperture of two inches. The tube being made as thin as possible, is easily balanced by the weight A, which is fixed in the semi-circle B B; (see fig. 3. of Plate XI.) then again all the parts above the horizontal axis (the end of which is seen as C) are balanced by the square weight D. By means of these balances the centre of gravity is preserved over the centre of the instrument in every position, and the different parts prevented from being strained when the instrument is put into any oblique position, which may be required in its various uses. This also tends to keep the telescope steady, which is of the greatest advantage in making an observation. Besides these very essential improvements, every part has been reduced to the most simple state; and several, which in other instruments of this kind, were found superfluous, have been entirely rejected.

The instrument is supported by three feet E, E, E; the screws *a, a, a*, are to raise or depress the feet, in order to bring the plate G G into an horizontal position, which is determined by two spirit-levels *b, b*, that are fixed on it at right angles to one another. If these levels are well adjusted, the plate will be horizontal when the air-bubbles come into the middle of the glass tubes. As this plate represents the horizon of the place, it is called the horizontal plate: it is divided into half-degrees, and by a vernier *c* of thirty divisions is subdivided to every minute. This index is made to move round the centre of the horizontal plate in order to set it to zero, or point *o*, when that point is found to be in the plane of the meridian. The plate is moved round by turning the handle *d*. The worm-screw, which works in the part *e*, may be easily disengaged from the plate, when any considerable quantity is required to be moved at once. Press the handle *d* outwards, and the worm will be disengaged. The plate F F is called the equatorial plate, as it represents the plane of the equator; it turns on the horizontal axis C, so that it may be inclined according to the latitude of the place, which is shewn on the latitude arch *f f*, that passes through the square weight D: this arch is divided into 90°, and by the vernier is subdivided into every minute. The tube *g* is fixed to the horizontal axis, close under the centre of the equatorial plate. An axis is fixed to the middle of the plate, which passes through the tube *g*, into a centre fixed in the square weight; this axis tends greatly to secure the equatorial plate from swaying, when put into different inclinations, or when the telescope is turned into any oblique position.

The horizontal axis is made parallel to the horizontal plate by turning the screw *b*, which will raise or depress that end of it. When the equatorial plate is inclined nearly to the latitude of the place, the clamp *i* may be tightened by the screw at the side; then, by turning the finger-screw *k*, it may be adjusted to the greatest exactness: the vernier *l* may be adjusted, (in case any error should be found,) by the small screws at *m*.

The equatorial plate is divided into twice XII hours; these

## EQUATORIAL.

these are subdivided into every two minutes of time, and by the vernier *n* again subdivided to every four seconds. This plate is moved round by turning the handle *O*. The worm-screw which works in the edge may be disengaged from the plate, by pressing the handle *O* outwards.

Above this plate is the semi-circle *BB*, which is called the declination semi-circle; this is divided into twice  $90^\circ$ , and subdivided as the other circles are; it is fixed to the axis *H*, which may be made parallel to the horizontal axis by the screw *p*, in the same manner as the horizontal axis is made parallel to the horizontal plate. On this declination semi-circle the telescope *II* is supported, and being balanced by the weight *A*, is moved with the greatest ease, by means of the pinion fixed at *q*, which is turned with the fingers at *r*.

To set the line of collimation of the telescope at right angles to the axis *H*, the wires in the eye-tube *s* may be moved in an horizontal direction by the screws, which will be discovered when the part of the eye-tube *t* is taken off; this piece carries the eye-glasses, and is made to slide on the part that contains the wires, that distinct vision may be obtained by eyes of different convexities. There are four eye-tubes, intended for different purposes, producing magnifying powers from 40 to 60, and an eye-piece with a diagonal speculum is sometimes added for gaining a convenient view of stars near the zenith. There is a combination of lenses to the number of four in one of these eye-tubes; and the enlargement of the field of view thereby affords a pleasing view of the heavens. Besides these, there is a sliding piece containing smoked glasses to guard the eyes of the observer from the sun's rays, which glasses are smoked but faintly at one end, and have the shade of darkness gradually increased towards the other to suit all states of illumination. There is also a semi-ring fitted by friction to the tube of the telescope, near the object end, which bears an arm holding a small diagonal reflector to direct the light of a lamp or candle into the tube so as to enlighten the cross wires contained in one of the eye-tubes.

The compass box, placed on one side of the horizontal plate, is useful in ascertaining nearly the meridian line, and also in detecting the variation of the magnetic needle at any time. These were the original parts composing the instrument before us; and the instrument viewed as a whole piece of mechanism presents a slightly compact figure, but the circumstance of the declination-semicircle, not allowing the telescope to reach as high as the pole, is an objection in the construction of this instrument, which, we are obliged to confess, renders it of less value in our estimation than it otherwise would have been. When the instrument is to be adjusted for observation, the horizontal plate is levelled by the levels in the first place, and then the equatorial plate is made parallel to the equator itself, by moving the square weight along the arc *ff* till the vernier *l* marks the latitude of the place. The directions given for the uses of Mr. Short's instrument will equally apply here as far as they go, but as this instrument professes greater accuracy in the readings than that of Nairne's, its uses are more extensive; for it will serve occasionally for an equal altitude instrument, a transit instrument, a quadrant or sextant, an azimuth circle, a theodolite, and a level.

When this instrument is to be used for observing equal altitudes, bring zero on the equatorial plate to zero on the vernier *z*, by the handle *O*, and zero on the vernier *l* to  $90^\circ$  on the latitude arch, taking care that the clamp *i* is made fast by the screw at the side; adjust the horizontal plate very nicely by the two levels and feet screws, then by turning the handles *d* and *r* bring the telescope to the sun for the morning

observations: in the afternoon set again the horizontal plate level, and the declination-semicircle to the degree and minute shewn at the corresponding morning observation; then bring the telescope to the sun by turning the handle *d* only. In this manner several corresponding altitudes may be observed on the same day, and the instrument used in the mean time for other purposes. For the methods of making equal altitudes serviceable in the practice of nautical astronomy, see problems X, XI, XII, and XIII, in our article CHRONOMETER.

To convert this equatorial into a transit instrument, bring zero on the vernier *l* to  $90^\circ$  on the latitude arch, and fix the clamp *i*; level the horizontal plate, and bring the telescope to the meridian mark, supposed to be ascertained, by turning the handles *d* and *r*: turn now the handle *r* alone, and it will raise the telescope in the plane of the meridian, so that when the sun or stars are seen to pass the vertical wire, they will then be upon the meridian, and the time may be noted accordingly. This application supposes of course the axes of the declination-circle perfectly parallel to the horizon plate, and also the line of collimation perfectly parallel to the same plate, but at right angles to the former, when the vernier is at zero. These verifications, however, we think, demand the levels to be applied nearer to the telescope than on the horizon plate only.

When the instrument is in the position just described, let the moveable vernier *c* be put to zero on the horizontal plate and be made fast, then turn the handles *d* and *r* to bring any celestial object into the field of view of the telescope, and its azimuth will be shewn on the horizontal plate, while at the same time its altitude will be indicated on the declination semi-circle.

When used as a theodolite, let this instrument have its horizontal plate levelled as before; then bring zero on the equatorial plate to zero on the vernier *z*, and also zero on the vernier *l* to  $90^\circ$  on the arc of latitude, and fix the clamp *i*. Turn the horizontal plate and declination-semicircle, so as to gain a view of the object whence the angle is to be measured; then bring the telescope to the second object, by moving the equatorial plate and declination-semicircle without the horizontal plate, and this last plate will then shew the measure of the said angle; and if there is any elevation or depression of the latter object compared with the first, the declination-semicircle will point it out. The bearings, also, will be shewn by the compass, as in the common theodolite.

When zero on the semicircle is brought to zero on the vernier *y*, the instrument then becomes a level; so that by turning the equatorial plate round, an observer may see what objects are level with the telescope. For this purpose also, our opinion is, that the level would be much better applied parallel to the telescope, on the declination-semicircle itself.

The late Mr. John Dollond had invented his object-glass micrometer previously to his arrangement of the circles and other parts of his equatorial instrument, seeing Dr. Maskelyne gave a paper on it to the Royal Society, which was read Dec. 12, 1771, which micrometer was sometimes made an appendage to his equatorial; but as this addition is not peculiar to the instrument in question, but may be applied to any other astronomical instrument, or even a common telescope, we will describe it hereafter, under our article EQUATORIAL Micrometer. We must not, however, omit a notice of the refraction apparatus belonging to the equatorial instrument, as made by the Dollonds, an account of which was read before the Royal Society on March 4, 1779, as drawn up by Mr. Peter Dollond, and presented by  
the

## EQUATORIAL.

the astronomer royal. *Fig. 3. of Plate XII. of Astronomical Instruments*, is a representation of this apparatus, detached from the object end of a telescope. The account itself, being short, will admit of being transcribed.

“The refraction of the atmosphere,” says the author, “occasions the stars or planets to appear higher above the horizon than they really are; therefore a correction for this refraction should be made in a vertical direction to the horizon. The equatorial instrument is so constructed, that the correction cannot be made by the arches or circles which compose it, when the star, &c. is in any other vertical arch, except that of the meridian; because the declination arch is never in a vertical position but when the telescope is in the plane of the meridian.

“To correct this error, a method of moving the eye tube, which contains the wires of the telescope in a vertical direction to the horizon, has been practised; but as the eye-tube is obliged to be turned round, in order to move it in that direction in the different oblique positions of the instrument, the wires are thereby put out of their proper situation in every other position of the instrument, except when it is in the plane of the meridian; for the equatorial wire should always be parallel to the equator, that the star in passing over the field of the telescope may move along with it, otherwise we cannot judge whether the telescope be set to the proper declination, except at the instant the star is brought to the intersection of the wires, which is only a momentary observation.

“The method I have now put in practice for correcting the refraction of the atmosphere, is, by applying two lenses before the object-glass of the telescope; one of them convex, and the other concave; both ground on spheres of the same radius, which in those I have made is thirty feet. The convex lens is round, of the same diameter as the object-glass of the telescope, and fixed into a brass frame, or apparatus, which fits on to the end of the telescope. The concave lens is of the same width, but nearly two inches longer than it is wide, and is fixed in an oblong frame, which is made to slide on the frame that the other lens is fixed into, and close to it. These two lenses being wrought on spheres of the same radius, the refraction of the one will be exactly destroyed by that of the other, and the focal length of the object-glass will not be altered by their being applied before it: and if the centres of these two lenses coincide with each other, and also with that of the object-glass, the image of any object formed in the telescope will not be moved or suffer any change in its position. But if one of the lenses be moved on the other, in the direction of a vertical arch, so as to separate its centre from that of the other lens, it will occasion a refraction, and the image will change its altitude in the telescope. The quantity of the refraction will be always in proportion to the motion of the lens, so that by a scale of equal parts applied to the brass frame, the lens may be set to occasion a refraction equal to the refraction of the atmosphere in any altitude. If the concave lens be moved downwards, that is, towards the horizon, its refraction will then be in a contrary direction to that of the atmosphere, and the star will appear in the telescope as if no refraction had taken place.

“There is a small circular spirit level fixed on one side of the apparatus, which serves to set it in such a position, that the centres of the two lenses may be in the plane of a vertical arch. This level is also used for adjusting a small quadrant, which is fixed to it, and divided into degrees, to shew the elevation of the telescope when directed to the star; then the quantity of refraction answering to that altitude may be found by the common tables, and the con-

cave lens set accordingly, by means of the scale at the side, which is divided into half minutes, and, if required, by using a vernier, may be divided into seconds.

“It must be observed, that when a star or planet is but a few degrees above the horizon, the refraction of the atmosphere occasions it to be considerably coloured. The refraction of the lens acting in a contrary direction would exactly correct that colour, if the dissipation of the rays of light were the same in glass as in air, but as it is greater in glass than in air, the colours occasioned by the refraction of the atmosphere will be rather more than corrected by those occasioned by the refraction of the lens. We may conclude this description with the subjoined references to *fig. 3. of Plate XII.* which is a view of this apparatus:

“A A, the circular brass tube which fits on to the end of the telescope.

“B B, the oblong concave lens, in its frame, which slides over the fixed convex lens.

“C, the circular spirit level, which shews when the oblong lens is in a vertical arch.

“D, the quadrant to which the spirit level is fixed, for shewing the angular elevation of the telescope.

“E, the milled head fixed to a pinion, by which the whole apparatus is turned round on the end of the telescope, in order to set the oblong lens in a vertical arch.

“F, another pinion for setting the quadrant to the angular elevation of the telescope. By means of these two pinions the air bubble must be brought to the middle of the level.

“a a, is the scale, with divisions answering to minutes and half minutes of the refraction occasioned by the concave lens.”

The best portable equatorial instrument of the Dollonds; with a 17 inches achromatic telescope, is marked in their catalogue at 84*l.*; and their achromatic object-glass micrometer of the new construction, at 21*l.*

Were we to be guided by a simple comparison of this instrument and its refraction apparatus with Ramsden's, and to infer from thence which of the two was prior in point of time, we should be induced to place this before the other for obvious reasons, deduced from their comparative constructions, particularly the situation of the levels and refraction apparatus, and total elevation of the telescope; but, on minute inquiry, we found that Ramsden's was the first, and we can only account for the preference we are disposed to give it, from the circumstance of his having a patent, that precluded the latter, though his brother-in-law, from adopting his construction. If there is any real comparative advantage in Dollond's, now that his achromatic telescopes are generally made, it is that which arises from the graduation of the latitude quadrant, and the lightness of the whole instrument; Ramsden's weighing 59 pounds, and Dollond's only 30.

*Portable equatorial instrument by Fayer.*—We have already said that Mr. Fayer of White Lion street, Pentonville, has the possession of a large engine for cutting clock wheels, &c. the property of his uncle Troughton, which we have described under our article *Cutting-engine* as originally made by Rehe: this artist, during some of his hours not occupied by his engine, makes mathematical and philosophical instruments, and among others he has lately constructed a portable equatorial instrument for Mr. Lowe of Islington, which, we think, merits a place in our collection, as being not only an original one, but as possessing advantages likely to recommend it to public attention. This portable instrument differs from its predecessors chiefly in these respects; it has no azimuth circle fixed in a permanently horizontal position; it has its equatorial circle divided into degrees and

## EQUATORIAL.

and also into time, with two verniers reading at opposite points, one vernier reads to the accuracy of 30" of space, and the other to 2" of time; this circle has a long axis passing through a tube, like Troughton's large Coimbra instrument hereafter described, from which probably this part of the construction was taken; it may, therefore, be placed in a horizontal direction by its axis being placed firmly vertical, in which situation it becomes an azimuth circle; the telescope is fixed on the end of the axis of the declination circle, which idea corresponds with, and may have been borrowed from, Nairne's construction; this position allows any elevation of the telescope that may be required, and keeps the observer's eye at a distance from the other parts of the instrument, but injures the uniformity of the appearance of the instrument as a whole; the levels are applied, one on the common axis of the telescope and declination circle, and the other at right angles thereto, as a chord to the declination circle; and lastly, the declination circle is complete, with opposite verniers reading, like the other opposite verniers, to an accuracy of twenty or thirty seconds, according to the dimensions of the graduated circles, when nicely divided on Troughton's dividing engine. From such construction it is easy to perceive, that this little instrument possesses the advantage of having its telescope reversed as well as its circles with respect to the opposite verniers, which property greatly ensures the accuracy of the adjustments. After these previous remarks it will suffice to give a brief detail of the parts of this instrument as represented in *fig. 4. of Plate XI. of Astronomical Instruments.*

A, A, A, are three adjustment screws for levelling the circular stand to which the feet are fastened; B, B, are a pair of triangular frames fixed firmly to the said circular stand, and supporting the pivots of the horizontal axis, round which the tube C, attached to the axis, moves; at the summit of the more visible triangular frame B is an adjustable or sliding part Y, like that of a transit instrument, by which the telescope may be adjusted into the meridian, when previously placed nearly so by the feet. The graduated circle D, which may be either an equatorial or azimuth circle, accordingly as its axis is inclined or vertical, has a steel axis nicely fitted to revolve in the tube C, in any position of this tube with respect to the horizon; but the double vernier bar is fast to the inferior end of the tube, as may be seen in the figure: the posterior pivot of the horizontal axis, borne by the triangular bars B, B, projects, and has firmly attached to it the quadrantal piece E, partly hidden from sight in our view of the instrument; this quadrantal piece is graduated, and reads by a vernier as minutely as the other circles; it serves to set the equatorial axis parallel to the earth's axis, in which situation it may be clamped fast, as well as in a vertical, or indeed any other position, by a clamping screw out of sight in the present position applying to the quadrantal arch; F F is the declination circle, with its horizontal axis resting on a pair of vertical supports, carried by the upper end of the polar axis, that passes through the tube C, so that, when the telescope, attached to the axis of the declination circle, has any horizontal or rather oblique motion, the circle D moves with it, and indicates the distance moved along the equator, or in a circle parallel to it, when the polar axis is properly adjusted and clamped fast. The double vernier bar is on the posterior plane of the declination circle, and may therefore be viewed after an observation without danger of altering the position of the telescope. The level on the declination axis may be conveniently adjusted by turning the circle D half round, and by making the bubble keep the middle of the tube in both situations, which may be done, partly by the screws A, A, A, and partly by the screws of rectification of the level itself;

and zero of the declination circle may be put to zero on the verniers when the circle D is truly placed in an horizontal position, in which situation also zero of the quadrant E must coincide with zero on its vernier. Under these circumstances the levels will be competent to effect all that is required, and in the best way; and the instrument will possess all the various powers ascribed to a portable equatorial instrument when converted into the other instruments.

*Universal equatorial instrument by Mr. Ed. Troughton.*—The equatorial instruments we have hitherto described are all, properly speaking, portable, and consequently of a size not professing great accuracy in their readings. We now come to an instrument of larger dimensions, and one having its parts so arranged and adjusted, as to entitle it to rank among the first class of instruments employed in modern observatories. It is of the universal kind, and may be called moveable (in opposition to fixed) rather than portable, as it stands seven feet high, and is therefore too bulky to be carried by one man. It was finished in the year 1788 for the late Mr. J. H. Magellan, and sent by him to the university of Coimbra in Portugal, where we have said it has been unfortunately shut up in the dark. *Plate XIV. of Astronomical Instruments,* exhibits a perspective drawing, shewing all the principal parts of this excellent instrument in its equatorial position, which we propose to describe in the order of their ascent from the ground.

It will not be necessary to give any letters of reference to this instrument, as it is presumed the reader, who has made himself acquainted with the component parts of the preceding instruments, cannot be at a loss to accompany us in our description of the present instrument without the aid of alphabetical references. The basis is of mahogany, consisting at the inferior part of a strong tripod, and at the superior of a circular table; these are connected by three pieces diverging from the table downwards, and connected by diagonal crossing bars: this frame work is still further united by three vertical pillars near the centre, one of which is omitted in the drawing, in order to expose to view a more essential part. Immediately above the table, and parallel to it, is a very strong azimuth circle of brass, 24 inches in diameter; this circle, however, is not in contact with the table, but rests on its conical axis, that passes through a collar of brass, attached to the centre of the table, and is supported on its conical point on a stud fast to the centre of the tripod. This length of bearing, like that of Mr. Nairne's descending axis, keeps the azimuth circle steady in the horizontal line both in motion and at rest, which is a circumstance of the utmost importance. The tripod is furnished with three strong feet screws for the adjustment of the azimuth circle into a true horizontal position; and three handles, with each a Hook's joint, are attached respectively to those screws, that the adjustments may be made with the body in an upright position, or nearly so. The apparatus for quick or slow motion is screwed fast to the table, and clamps to the azimuth or horizontal circle. Two opposite verniers, reading to the accuracy of 10", are attached to the edge of the table, but in such a way that they are of ready adjustment to an exact bisection of the circle, in case the wood work of the table and frame should alter its figure by warping in the least degree; otherwise the wooden frame, as a pedestal, would have been objectionable. Upon the plane of the said azimuth plate are erected two vertical supporters of frame work, somewhat resembling the appearance of two chair backs; which supporters consequently have a motion in azimuth whenever the circle is turned round; they are 19 inches apart from each other, and an horizontal axis of this length binds them together at their upper extremities; the

## EQUATORIAL.

the posterior supporter has an adjustment apparatus for bringing the axis perfectly horizontal, which apparatus is hidden in the drawing behind the said supporter. At the middle of the horizontal axis called also the axis of latitude, is a cubical part similar to that in the axis of a transit instrument; to this the long brass socket or tube, that embraces the polar steel axis, is made fast, and is set exactly at right angles thereto by construction. The polar axis, that passes down through this socket, has the equatorial or hour circle attached firmly to it, at right angles also by construction, at its inferior end; and to its superior end above the axis of latitude, is fixed a small platform, of the shape of a parallelogram, to support the superstructure not yet described. Any additional weight may be fixed to the lower end of the polar axis, that the superincumbent materials may require to form an exact equipoise in any position; the sidereal time, depending on the horary angles, is read by opposite verniers, fixed to the inferior end of the long polar socket; one of which only can be seen in the figure of the instrument, as it stands in the drawing: the equatorial circle is divided, so that a single second of time is distinctly read by the verniers; and if the application of three verniers had been thought of when this instrument was constructed, the inequality of the divisions would have been corrected thereby still more perfectly, as well as the excentricity of the circle, if any exists; which observation will equally apply to the azimuth and declination circles. Two quadrants are made fast to the pivots of the axis of latitude, or horizontal axis already described, having their position just within the vertical supporters of the said axis, and consequently move with it, when it has any motion: these quadrants are divided, one of them agreeably to the usual divisions of the circle, and the other by particular desire into 96 equal parts with its subdivisions, and the two verniers are respectively placed on the contiguous supporters of the axis; the use of the quadrants is to fix the elevation or inclination of the polar axis agreeably to the latitude of the place of observation; that is, parallel to the axis of the earth; which position requires to be well verified when the instrument is used. Between the feet of the supporters, and at right angles to each other, are placed, on the plane of the azimuth circle, two nicely ground spirit levels, one of which is about half visible, and the other still less, which serve to place this circle perfectly horizontal in every direction, by the aid of the feet screws: and near the centre of the same circle may be seen an apparatus for adjusting and fixing the polar axis in any given degree of inclination from a horizontal to a vertical position, which it does with equal convenience, accuracy, and steadiness: the lower end of this apparatus may be screwed to any pair of the parallel holes made in the plate, farther from, or nearer to, the centre, as the quantity of inclination may require; while the upper end is attached to a broad ring embracing the socket of the polar axis; and about the middle is an adjustment screw, just above a Hook's joint, that allows the screw to act freely in any position of this apparatus. The ring that embraces the long socket of the polar axis will slide along it till the stem of the said apparatus, into which the screw acts, stands at right angles to the polar axis, in which situation its position will be firm and steady, as the axis can have no lateral or vibratory motion, by reason of its union with the axis of latitude. From this description of the apparatus in question it is easy to perceive that the nearer the polar axis approaches to a vertical situation, the farther from the centre of the azimuth plate must the fixing screws be inserted, and *vice versa*; also the lower towards the equatorial

circle must the sliding ring be, that embraces the socket; as well as the steadier the axis so fixed. Again, upon the platform on the superior end of the polar axis, already noticed, are erected a second pair of supporters, at the distance of 15 inches from each other at the bottom, and, bound together at the same distance at top by the axis of the declination, which consequently is 15 inches long; these supporters, which partake of any motion given to the equatorial circle, bear the declination or meridian circle, and telescope surmounted over all. At the upper end of one of these last named supporters is an adjustment for setting the declination axis at right angles to the polar axis, which is a very essential adjustment; the apparatus for producing quick or slow motion is fast to the platform, the milled nuts of which apparatus may be seen under the declination circle; also the opposite verniers for reading off the angles of declination are attached to the said platform, and both faces of the circle are divided, like the quadrants, one according to common usage, and the other into 384 divisions with their subdivisions, which, at the time of the construction, were considered by Mr. Magellan as the best check on the accuracy of the verniers that read off to 10". The elevated situation of the telescope, which is  $3\frac{1}{2}$  feet long, is sufficiently explained by the drawing, where some of the supporters are seen attached to the declination axis, and some to the circle itself; this elevation was given, that the eye-tube might keep clear of the supporters and other parts of the mechanism, when a star or planet is followed along the equator, or other circle parallel thereto; and as the declination circle is complete, the telescope will rise to any degree of elevation that may be required, while the circle will measure that elevation. As a tangent to the upper edge of the circle, and parallel to the line of collimation of the telescope, is a very sensible spirit level with proper adjustment screws; and on the upper side of the tube of the telescope are mounted two microscopes, the use of which is to observe the coincidence of a fine plumb-line with points made on the tube, when placed in a vertical position for the purpose of levelling the declination axis; and indeed many of the adjustments of this instrument may be verified both by the plumb-line and levels. There are various eye-pieces to answer different purposes, both with and without diagonal reflectors for high altitudes, which it is not necessary to describe here minutely, as they form no distinguishing feature of the instrument. Lastly, the refraction apparatus placed at the eye end of the telescope, as made by Ramsden, was an appendage of this instrument, and by moving the adjustable cross wire in the focus of the eye glass a quantity equal to the refraction or refraction and parallax taken together, rendered the calculations from the tables unnecessary, by converting mechanically the apparent into the true altitude of any observed body. The reading of the subdivisions of a circle by means of a microscopic micrometer had not been adopted at the period this beautiful and useful instrument was constructed, otherwise its powers would have been made more extensive than they now are by the verniers alone.

It is hardly necessary to add, that the powers of this universal instrument, as far as they go, may be readily and conveniently applied to almost all the purposes of practical astronomy, as well as of land-surveying and levelling; seeing it has all the properties ascribed to the preceding instruments, but in a degree approaching nearer to perfection. This is the only instrument of the construction here described that ever was made on so large a scale, but three or four others of an inferior size have since been made on the

## EQUATORIAL.

same plan; that, as portable instruments, can hardly be surpassed unless by the adoption of triple verniers, which are of recent origin.

*Adjustments.*—1. In the first place, the telescope must have its wire-plate turned round into such a position, that the middle vertical wire will coincide with a distant mark throughout the whole field of view, as the telescope is elevated or depressed, and then the object-glass must be slid in or out, till a star of the second magnitude is seen as distinctly as possible; to prevent parallax at the wires.

2. In the next place, make the azimuth circle horizontal by means of two levels, adjusting one half of the error, produced by turning the circle half round, by means of the feet-screws, and the other half by the levels, as with the preceding instruments.

3. Make the polar axis perpendicular; clamp it nearly so, and turn the declination circle round till the bubble stands in the middle of its level, now turn the upper part half round on the polar axis, and, if there is an error, correct one-half of it by the apparatus acting on the polar axis, at the azimuth plate, and the other half by turning round the declination axis by the slow motion. When the error has disappeared by a repetition of this process, turn the declination circle round the polar axis just six hours, and bring the bubble to the middle by the adjustment at the top of one of the supporters of the latitude axis: when this is done the azimuth and equatorial circles will be parallel to each other, and their axes perpendicular to the horizon; and, of course, the level near the telescope will keep its bubble at the middle, as well as the other levels, while either or both of these circles revolve. Here the verniers of the latitude-quadrants may be set to their respective zeros.

4. The declination axis must be set level, or at right angles to the polar axis. In order to do this, set the telescope perpendicular by fixing the declination circle with its vernier at  $90^\circ$ , and put on the plumb-line; by the motion of one of the points, which is adjustable, and also by the proper motion of the plumb-line; make the latter bisect both the points under the microscopes; reverse now the telescope by turning the declination circle to the opposite  $90^\circ$ , suspend the plumb-line from the contrary end of the telescope, and by the proper motion of the line make it bisect the fixed point; then half the error that appears at the adjustable point must be corrected by that adjustment, and the other half by that at the top of the supporter of the declination axis.

5. The line of collimation of the telescope must next be adjusted, both as it regards the right ascension and declination. In order to do this, let the upper end of the polar axis, and the object-end of the telescope, be pointed to some fixed object a little above the horizon, the declination circle being first put with  $90^\circ$  to the zero of its vernier, the hour index placed at XII, and the telescope above the polar axis; bring now the centre of the cross-wires to the object fixed on, by raising or lowering the polar axis in conjunction with a motion in azimuth, and read off the degrees, minutes, and seconds shewn by the verniers of the azimuth circle and quadrants respectively; in the next place, set the polar axis nearly vertical, and place the hour circle at the opposite XII, and point the polar axis, as before, to the said fixed object, the telescope being now below it; move the instrument as before, by a compound motion of the polar axis and azimuth circle till the intersection of the middle wires coincides with the object before fixed on and used, and read off, as before; the degrees, minutes, and seconds both on the azimuth circle and quadrants: in this

situation of things, set the azimuth circle to the mean of the two observed azimuths by taking half their sum, and also the polar axis to the mean of the two observed altitudes or inclinations of the polar axis; in this position of the instrument, let the telescope be carefully moved by altering the screws that fasten it to the circle, until the vertical central wire coincides with the original object, and the adjustment for right ascension is finished. Again, move the telescope, by altering it in declination, till the horizontal wire cuts the same object, and adjust the verniers of the declination-circle to the points  $90^\circ$  and  $96$  parts respectively on its opposite planes. If, however, the object is not a very distant one, the above directed adjustment in declination will not be quite correct, because the telescope stands higher, when above the pole than it is below; consequently, when this adjustment is made by means of a near object, two marks should be used on that object, the distance between which must be double the measure from the centre of the declination axis, to the line of collimation of the telescope; otherwise a small angle will be formed at the object, by the two lines of sight, which angle will be subtended by the double distance in question; but when the object is at an infinite distance this small subtense is reduced in effect to nothing, and the same mark therefore will do in both the positions of the telescope.

6. To adjust the hour index let the point  $90^\circ$  of the azimuth circle be turned to an object of small altitude; let the polar axis be made horizontal; and the telescope be set to  $0^\circ$  of declination: in this position the hour circle becomes vertical, and the altitude of the object may be taken by it, which must be read off in time from VI hours: turn now the instrument half round in azimuth, and make the telescope look towards the object by turning round the polar axis; take another altitude in this position, and read off what is indicated from the opposite VI hours, and the mean of these two altitudes is the exact place where the adjustable index must have its zero placed to be in its true position.

The apparatus for correcting the horary angle on account of refraction consists of a small quadrant and level for taking altitudes, which are moveable round the axis of vision, and therefore determine very readily the elevation of the telescope in any given position; also the eye-piece and wires of the telescope being moveable by means of a nice micrometer screw, may be set with great accuracy to the refraction corresponding to the altitude of the observed body as determined by the small quadrant and level.

The chief advantages resulting from the construction of the equatorial instrument just described, are, first, that it affords a firm support to a very long, and, therefore, powerful telescope; and, secondly, that the great range of polar distance beyond  $90^\circ$  of declination renders an observation with the telescope below the polar axis unnecessary.

As the rules we gave for using Ramsden's portable instrument, as extracted from professor Vince's treatise, are not exemplified by actual observations, and as rules, however plain, are not always understood without the illustration of appropriate examples, we cannot finish our account of the present instrument better than by subjoining to the rules given by the Hon. Mr. M<sup>c</sup>Kenzie his examples given at full length, when adapted to our purpose, by which the reader will be led to have an idea of the practical application of the observations to the various purposes of astronomy. The rules were originally written as directions for the use of Ramsden's instrument, but after our account of the adjustments,

# EQUATORIAL.

ments, they are equally applicable to the instrument under our immediate consideration.

*Observation 1. To find the latitude of the place by the sun, or any known fixed star.*—The instrument being perfectly adjusted in all its parts according to the directions given,—

Make the polar axis perpendicular to the horizon, and when the sun approaches his meridian altitude, elevate the telescope to that altitude, and adjust the refraction apparatus as above directed: then follow the sun by moving both the equatorial and declination circles (if necessary), and keeping the refraction piece always adjusted till he is at his greatest altitude; the vernier of the declination circle will then give you his meridian altitude; from which subtract his declination, if it be north, or add it if it be south, the remainder if north, and the sum if south, is the height of the equator, that is, the complement of your latitude, which being subtracted from 90°, gives your latitude.

### Example.

Sun's declination supposed	- 6° 57' 37" North.
Meridian altitude of his centre observed	45 6 29
Subtract his declination	- 6 57 37
	38 8 52
Height of the equator or co-latitude	38 8 52
Which subtracted from	- 90 0 0
	51 51 8
Gives your latitude	51 51 8

If instead of observing the altitude of the centre, you observe that of the upper or lower limb of the sun, you must allow for the semi-diameter of the sun, which allowance you find in the Nautical Almanac. Also, if the refraction apparatus were not used, the tables for refraction and parallax in altitude must be used to reduce the apparent to the true altitude.

*Observation 2. To find the meridian by one observation only.*—Elevate the equatorial (or hour) circle to the co-latitude of the place, set the declination circle to the sun's declination for the day and hour required; and adjust the refraction apparatus, then move the azimuth and hour circles both at the same time (either in the same or a contrary direction) till you bring the centre of the moveable wires (the vertical being truly perpendicular) exactly to cover the apparent centre of the sun; that done, the centre of the fixed wires will be in the true centre of the sun, the index of the hour circle will then give the apparent or solar time at the instant of observation. Thus you get the time though the sun be at a distance from the meridian. Then turn the hour circle till the index points precisely at 12 o'clock, and lower the telescope to the horizon to observe some mark in the centre of the telescope, and that is your meridian found by one observation only.

The best time for finding the meridian is, when the sun is three hours distant from the meridian on either side of it.

Observe, that when you have once a true meridian fixed, you need make no use of the refraction apparatus in any observation, except to set one of the moveable wires perpendicular.

The meridian and solar time may be found in like manner by a fixed star, whose declination and right ascension are known.

*Observation 3. To observe a star or planet in broad daylight, at any time when it is above the horizon.*—The table of right ascensions, declinations, &c. of Dr. Maskelyne's 36 principal fixed stars, under the articles CHRONOMETER and DECLINATION, gives you the times of their transits over the meridian in sidereal time.

Elevate the equatorial circle to the co-latitude of the place, and set the vernier of the declination-circle to the star's declination, then adjust the refraction piece; look into the table for the time of its meridian transit or right ascension; then take the time of the said transit from the time of your observation as given by the sidereal clock, borrowing 24 hours if necessary; this difference is the hour to which you must set the hour index of the equatorial circle, and the star will then appear in the telescope.

*Example 1.*—Let it be required to place the telescope of the equatorial instrument to observe Capella on Sept. 30th 1809, exactly at 9<sup>h</sup> 0<sup>m</sup> 0<sup>s</sup> by a sidereal clock well regulated?

Declin. of Capella from Tab. III. under	
CHRONOMETER, 1806	45° 47' 5."88 North.
3¼ years of annual variation add from	
ditto	0 0 17.14
	45 47 23.02 North.
Right ascension or sidereal time of	
transit from ditto, 1806	5 <sup>h</sup> 2 <sup>m</sup> 22."62
3¼ years annual variation add	0 0 16.55
	5 2 39.17
True time of transit	5 2 39.17
Which subtract from sidereal time of	
observation	- 9 0 00.00
	3 57 20.83
And there remains the interval since the	
transit for the index to be put to	3 57 20.83

Note, if the clock shews solar time, it must be converted into sidereal time by problem VI. under our article CHRONOMETER, and then the work may be done as here directed.

*Example 2.*—Let it be required to find Arcturus on April 1st, 1810, when the sidereal time is 10<sup>h</sup> 30<sup>m</sup>?

Declin. of Arcturus 1806	- 20° 11' 59."41 North.
4¼ years annual variation subtract	0 1 19.85
	20 10 39.56 North.
Right ascension or sidereal time of	
transit	- 14 <sup>h</sup> 6 <sup>m</sup> 48."83
4¼ years annual variation add	0 0 11.59
	14 7 0.42
True time of transit	14 7 0.42
Which take from the time of observa-	
tion, borrowing 24 <sup>h</sup>	- 34 30 0.00
	20 22 59.58
The remainder is the place of the index	20 22 59.58

In this observation Mr. McKenzie used a table of meridian passages given in solar time, which required the acceleration of sidereal or solar time to be used; but as the principal catalogues give the passages in sidereal time, we have adapted his rule thereto.

*Observation 4. To find the right ascension and declination of a planet, comet, or fixed star.*—The equatorial circle being elevated, as before, to the complement of the latitude of the place, move the declination and equatorial circles till the planet or comet is in, or near the centre of the field of the telescope, then adjust the refraction piece, and bring the centre of the moveable wires to cover the planet, the vernier of the declination circle will then give you the declination of the planet, and the vernier of the

# EQUATORIAL.

equatorial circle will give you the hour of the planet, &c.; then your regulator or clock will give you the sun's time or hour of the day. Take the difference between the sun's time and the planet's time; and if the planet's time be less than the sun's time, add that difference to the sun's right ascension at the time of observation, (which you find in the Nautical Almanac,) the sum (rejecting 24 hours, if it exceeds that number) is the right ascension of the planet, &c. Again, if the planet's time exceeds the sun's time, subtract the difference from the sun's right ascension; the remainder (adding 24 hours to the sun's right ascension, if necessary,) is the right ascension of the planet, &c.

### Example 1.

Observed a star whose time by the equatorial circle is	2 <sup>h</sup> 18 <sup>m</sup> 3' P.M.
Sun's time as given by the regulator, viz.	9 44 40 P.M.
Difference between the two	7 26 37
As the star's time is less than the sun's, add that difference to the sun's right ascension	20 57 9
Reject 24 hours from	28 23 46
Right ascension of the star is	4 23 46

Its declination (by the vernier of the declination circle) is 16° 2' 50" north.

### Example 2.

Observed a star whose time by the equatorial circle is 10 <sup>h</sup> A.M. (that is, astronomically)	22 <sup>h</sup> 0 <sup>m</sup> 0 <sup>s</sup>
Sun's time as given by the regulator, viz. 5° 55' 4" A.M. (that is, astronomically)	17 55 4
Difference between the two	4 4 56
As the star's time exceeds the sun's, subtract that difference from the sun's right ascension	10 38 58
Remains the right ascension of the star	6 34 2

Its declination (by the vernier of the declination circle) is 16° 25' 1" south.

### Observation 4. To find the longitude at land by the right ascension of the moon.

Observed the centre of the moon on the moveable wire set vertical, either in or out of the meridian; time given by the equatorial or hour circle, suppose	2 <sup>h</sup> 28' 2"
Sun's apparent time by the regulator	6 0 0
Difference between those times	3 31 58
Add that difference to the sun's right ascension at 6 hours (because the moon's time is less than the sun's time, for had it been greater, the difference must have been subtracted)	8 25 27

And you have the moon's right ascension at the place of observation at 6 hours	11 57 25
--	----------

*Another method of making the above observation.*—The centre of the moon being observed in the same manner at six hours P.M. as before directed, let the instrument remain in the same position it was in (only altering the declination) till a known star comes to the vertical wire, which will happen (suppose) in one hour after, viz. at 7 hours, then subtract that one hour of difference in time of transits, with the addition of 9" 86<sup>4</sup> for the acceleration corresponding to one hour, that is, subtract 1<sup>h</sup> 0' 9" 86<sup>4</sup> from the AR of the star, supposed to be 12<sup>h</sup> 57' 35", the remainder is the moon's AR at six hours P.M. at the place of observation.

Star's right ascension	12 <sup>h</sup> 57' 35"
Difference in sidereal time, (see CHRONOMETER, Tab. I.)	1 0 9.86

Moon's right ascension at 6 hours P.M. at the place of observation.	11 57 25.14
---	-------------

Then find, by the Nautical Almanac, at what time at Greenwich the moon has the same right ascension as that now observed.

Moon's right ascension at Greenwich at noon is	11 <sup>h</sup> 43' 20"
Ditto at midnight	12 10 36

Difference in those 12 hours	0 27 16
------------------------------	---------

Moon's right ascension at Greenwich at noon 11 <sup>h</sup> 43' 20"	
Moon's right ascension at 6 hours, at the place of observation	11 57 25

Difference between them	0 14 5
-------------------------	--------

### Proportion for finding the time at Greenwich.

$$\text{As } 27^m 16^s : 14^m 5^s :: 12^h : 6^h 12^m 0^s$$

So that the time at Greenwich, when the moon has 11<sup>h</sup> 57' 25" of right ascension, is 6<sup>h</sup> 12<sup>m</sup> 0<sup>s</sup>, that is, 12<sup>m</sup> later than at the place of observation, which is therefore 12<sup>m</sup> of longitude west from Greenwich.

*Sir George Shuckburgh's fixed equatorial instrument.*—A B, C D, E F, G H, (Plate XV. of *Astronomical Instruments*,) are four columns, says Sir George Shuckburgh, composed of hollow brass tubes 3½ inches in diameter, and five feet ten inches long; these, with two others, one of which appears in part at I K, and the other partially hidden behind E F, are firmly fixed, at their upper ends, to a circle of bell metal B D F H, and, at their lower end, to an inverted truncated hollow cone, L L L, of brass, in height two feet, and in diameter, at the base A G, one foot nine inches. The cross pieces, or tubes P, P, as likewise O, O, and O, O, serve to connect the columns more strongly together, and prevent their bending. These several parts constitute the principal axis of the instrument, the lower end of which terminates in a steel point or cone, resting in a hollow conoid of bell metal, in such manner that the apex of the former does not reach to the bottom of the latter, but the place of bearing, or of friction, is (it may be) about two-tenths of an inch from the extremity of the cone; the other end of this axis finishes in a cylindrical pivot N, of about 1¼ inch long, and one inch in diameter, turning in a Y of bell metal. The entire length of this axis is eight feet four inches, the lower end being supported by an iron frame 3, 4, 5, 6, 7, 8, which is firmly fixed below the floor, into brick-work, and by means of two iron bars, one of which is seen at 28, and the other on the opposite side, not visible in the drawing, is kept

## EQUATORIAL.

kept secure from any motion, eastward or westward; the lower part of this frame, to about one foot high, is inclosed by a mahogany box or case 9, 10, the top of which is entirely covered up, and serves as a die or base to this end of the instrument. The other extremity of this long axis, *viz.* the pivot N, rests upon the strong iron support 29, 30, 31, standing 10 feet above the floor, made of massive pieces of cast iron,  $2\frac{1}{2}$  inches wide, and  $\frac{1}{2}$  an inch thick, and held firmly by bolts and nuts as in the figure: 32, and 33, are the places where two iron bars, nearly at right angles to each other, and at  $\frac{1}{2}$  right angles to the meridian, are screwed, to connect this upright support with the walls of the building, and going through the bricks, are held fast by iron collars and nuts on the outside of the wall; these bars, or braces, not in the figure, resist any tendency from the weight or pressure of the instrument, to push the supporter 29, 30, and 31, out of its upright position; and being at right angles to each other, serve to keep it steady with respect to any lateral force that may accidentally be applied. The lower part is continued below the floor, and firmly fixed with mortar and lead into the brick work of an arch. The bottom is shut up in a box or plinth of mahogany, 34, 35, as has been mentioned in the description of the frame supporting the other end of the axis at 9, 10. Near the lower end of the principal axis L N, are inserted 10 concentric brass cones, or radii, *a a, b b, c c, d d, e e*, carrying on their extremities a graduated brass circle, of  $49\frac{1}{2}$  inches diameter, at right angles to the principal axis already described; this circle has two sets of divisions, one of points, and one of lines, each into degrees, and every ten minutes, and the intermediate minutes and seconds are read off by the microscopes W and X, with a moveable wire, and micrometer screw, such as has been described in general Roy's account of his instrument for measuring horizontal angles. (See Philosophical Transactions, vol. lxxx. p. 145.) The circle just mentioned, is inclosed by a circular frame, or rail of mahogany, 14, 15, which is supported by ten balusters, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, (17 and 24 being concealed) and serves to protect the brass circle from any accidental injury in passing by it, without depriving it of exposure to the general temperature of the room. It at the same time affords means of support to a small lamp, 13, which, by reflection from the perforated speculum at the bottom of the microscopes, to be seen in that marked X, throws light upon the divisions by night: 26, 26, and 27, are iron rods that, by being attached to the wooden case, 9, 10, give steadiness to the upright balusters, and the circular frame that they support: 1 and 2 are large stout brass cones firmly fixed into the frame, 3, 4, 5, 6, 7, 8, before mentioned, and whose use is to carry the microscopes W, X. Any degree of pliancy or flexure in these cones would be readily discernible in the microscopes, and extremely detrimental to the observations; they are therefore made as stiff as possible: 3 is a plane forming the upper side of the frame, 3, 4, 5, 6, &c. and consisting of three plates, two moveable in grooves; and one fixed, furnished with suitable screws, one giving the extremity of the axis a motion upward or downward, and the other a motion to the right or left. This latter is procured by a rod passing through the cone 2, one end screwing into the plate below L, near the centre, and the other turned by an occasional handle fixed on, near X, the former motion, *viz.* of elevating or depressing the axis, is procured by a handle fixed on to a screw near: Q R is another circle of the same dimensions with the former, graduated in the same manner, and held together by eight conical radii, *f f, g g, h h, i i*, firmly screwed to a circular centre-piece, which serves as a base to a large conical axis, two

feet three inches long, one side of which is seen at U, and its exterior extremity near V, with its sliding plate and screws for adjustment. Close behind the graduated circle, and at right angles to this axis passing through it, lies the telescope T S,  $5\frac{1}{2}$  feet long. This circle is likewise furnished with two microscopes and micrometers, as in the equatorial circle, one of which is seen at full length at Y, and Z, the eye-tube being at Y, and the object-glass, with the perforated speculum, to throw light at Z; the other microscope, on the opposite side of the circle, is not so prominent in the drawing, being somewhat fore-shortened at Z. Near T,  $\alpha, \alpha, \alpha, \alpha, \alpha, \alpha$ , is an hexagonal lozenge, composed of six brass rulers, firmly fixed to the columns A, B, and E, F, and supporting the lower end of the microscopes, as the pieces  $\beta \beta, \beta \beta$ , in like manner sustain the upper end. By these means, the wire in the field of the microscopes becomes a fixed immoveable index, and after proper adjustment, an exact diameter of the circle, whilst the telescope, together with the circle, turns round the conical axis before-mentioned. At P is a spirit level, passing through the centre plate of the conical axis at right angles to the telescope, supported by a cock at each end, one of which appears at *h*; this cock is placed on the cone U; and by means of a small-toothed wheel and pinion, the level is made to revolve round its own axis, so that the same side of the level may readily be brought uppermost, whatever position the circle be put into; it is also furnished with all necessary adjusting screws. It will readily be seen, that a telescope thus fitted up, will have all the properties of a transit instrument, while the graduated circle will possess those of a meridian quadrant. For this purpose *l m* is a stout brass tube, inclosing a stiff iron rod, turning upon two fine steel points, adjusted by proper screws, parallel to the line of sight of the telescope: this rod is attached to a spirit level of great sensibility, lying below it, which, with the rod, turns round upon the steel points just mentioned, and is in fact a hanging level of the best construction. At the eye-end of the telescope S is a peculiar apparatus, to correct the effects of refraction and parallax, when an observation is made out of the meridian: it is composed of two levels, a small quadrant of altitude *n o*, and a semicircle divided with its vernier to every  $5'$  on the breech plate of the telescope, the exterior eye-tube having a circular motion by a wheel and pinion at *o*, independent of the tube that carries the cross wires; by this means the angle of the horary and vertical circles may at any time be found, together with the altitude of the object, and then by the resolution of two right-angled triangles the refraction and parallax in right ascension and declination will be obtained: *t, u*, are two handles to a Hook's joint at  $\alpha \alpha$ , which turning an endless screw at *w w*, give a gradual motion to the telescope in right ascension or declination; and this motion can at any time be restrained by a clamp at *q*: 11, 12, (the latter not seen,) are two supporters to the clamp and endless screw. The handles *t, u*, are hung on to any part of the instrument by means of the line and wire *v, v*, and are thus kept within the observer's reach. Near *r* and *s* are two microscopes, placed on opposite sides of the circle Q R, and at right angles to the line of sight of the telescope, but are hidden by the columns in our figure; they are of use only when the plumb-line, suspended from the roof of the observatory, is used in preference to the level *l m* above described, either for adjusting the instrument, or observing a meridian altitude, in which case the line must bisect the centres of both microscopes: *y*, and *z*, are thin perforated brass plates, attached to the cover that goes on the object-glass, and by occasionally turning them over it, change the aperture to  $\frac{1}{2}$  or  $\frac{1}{4}$ . The cross wires, of which there are three.

three vertical and one horizontal, within the eye-tube S, have all the requisite adjustments by screws, &c. as in a common transit instrument, and are enlightened at night by a lamp fixed near to one end of the declination axis U, viz. that opposite the end V; but this part of the apparatus is hidden behind the axis and the telescope, except the weight *i*, which is a counterpoise. This lamp throws a light through the conical axis, which is perforated at that end on purpose, on a speculum in the centre of the telescope, placed at  $\frac{1}{2}$  right angles to the axis of the object-glass, and from thence reflected to the cross-wires. This speculum, which is an elliptical diaphragm, is perforated to permit all the rays from the object-glass to pass unobstructed to the eye. The contrivance has been mentioned by Mr. Vince (*Practical Astronomy*, p. 80.) From what has been already described, it must now be evident that if the principal, or polar axis, as it has been called, L N, be elevated to the latitude, and adjusted to the meridian of the place, if the line of sight of the telescope be at right angles to the axis V U, and this latter at right angles to the polar axis L N, the brass circle 14 and 15 will correspond with the equator in the heavens, and the circle Q R will become an horary circle; that is, if the centre of the wires in the field of the telescope be directed to any celestial object, on Q R will be had its declination, and on 14 and 15 its distance from the meridian, from whence, by knowing the hour, the right ascension will be obtained, and consequently its true place in the heavens.

Besides the preceding parts of this expensive instrument, there are some necessary appendages, as a stool marked 36, and some others described in the original account, with references to the accompanying plates, a minute detail of all which would lengthen this article too much; we will therefore briefly enumerate them, and refer the more curious reader to the Transactions themselves for the particulars. The appendages are, 1st, a lamp to illuminate the cross-wires; 2dly, the refraction-piece hereafter described; 3dly, the plumb-line; 4thly, the moveable roof of the observatory; 5thly, a regulator or sidereal clock which indicates degrees, minutes, and seconds of space on the equator; and, 6thly, the meridian mark, consisting of a small adjustable light-house, placed on a brick pier at the distance of 2970 feet, which can be seen as well by night as day.

After a very rigorous examination of the two divided circles of this instrument, it seems that the greatest error, including both the inequalities of the divisions and the eccentricity, never amounts to more than 2" in either of them, and the author calculates that an observation of right ascension, taken out of the meridian, may be depended on to the accuracy of 5", allowing an error of 2" for counting the beat of the clock, 1" for the deviation of the meridian mark, and  $\frac{2}{3}$ " for the error in reading the microscope; but that the error in polar distance may amount to 7", including all the errors of the instrument, of the adjustments, and of the readings. This instrument, it will have been observed, has no azimuth circle, like most of the portable instruments, but if its axis were fixed perfectly vertical, its equatorial circle would then become an azimuth circle, and the instrument altogether would greatly resemble Piazzi's great circular instrument made by Ramsden. From what we apprehend also from sir George Shuckburgh's account of the variableness of the errors of adjustment, in different degrees of temperature, we are disposed to attribute much of the imperfection of this instrument, in this respect, to the metallic support of the upper pivot of the polar axis, which support must naturally elongate and contract its dimensions alternately, by changes of temperature; and as it is composed of various parts differently placed, it affords no data

for ascertaining by calculation either the quantity or direction of deviation from the truth. Before we proceed to the adjustments of this instrument, it may be proper to describe the refraction apparatus which is attached to it, and which is necessary to be understood in using the appended tables. Fig. 2. of Plate XI. exhibits a perspective view of this apparatus on a larger scale than is exhibited in fig. 1. where "A B is a portion of the telescope; C the eye-tube; *a b c* a divided semicircle, *d* its vernier fixed to A B, shewing the angle of the horary and vertical circles; *e* a small spirit-level, attached to the plate on which this semicircle is engraved, and moving with it by means of the screw *f*, which turns a pinion, that works in a toothed wheel, that turns the whole plate, together with the exterior eye-tube round its centre, but without moving the tube that carries the cross-wires. From hence it may be understood, that by turning the screw *f* till the level *e* stands true, the index *d*, which represents a point in the horary circle, will mark how much the division zero, which represents the vertical, is inclined thereto. *l k* is a small quadrant of altitude, that, by means of the level *g*, and screw and pinion *b*, turning on a centre at *m*, gives the elevation above the horizon of any object in the field of the telescope: *i* is a small aperture through which a key is fixed on, to give a lateral motion to the wires to adjust them; and near *f* is another screw, to adjust them parallel to the equator and declination-circle."

This apparatus, it will be seen, has not the refraction-circle, or micrometer and divided nut, to elevate or depress the horizontal wire, a quantity corresponding to the data thereby determined, in order to convert the apparent to the true place of a heavenly body; it therefore indispensably requires the aid of such tables as we have subjoined to our present article; but Ramsden's portable instrument described by the Hon. S. M<sup>r</sup> Kenzie, and by professor Vince, whose accounts we have adopted, has the addition of the micrometer seen in miniature at P, in the figure of that instrument. To that instrument, therefore, as well as to Dollond's, the tables are otherwise unnecessary, than as they serve as a check on the accuracy of the mechanical contrivances in question.

*Adjustments.*—The three principal adjustments, according to sir George Shuckburgh's account, are, 1st, to adjust the level P *k* parallel to the declination axis U V; 2dly, to adjust this axis at right angles to the line of collimation of the telescope; and, 3dly, to make this axis at right angles to the polar axis. The polar axis is placed nearly in the meridian, by means of a meridian mark previously verified, and elevated pretty nearly to the latitude of the plate. This is to be done more accurately afterwards, by the sliding plates and screws at the bottom of the polar axis. The axis of the declination-circle is then brought nearly horizontal, by its proper level, viz. is turned round about the polar axis, till the bubble of the level stands true between the indexes; the instrument is then turned half round about the polar axis, = 180°, shewn by the microscope W. If the bubble then stand true it requires no correction, but if it do not, correct half the error, by moving the equatorial circle by its handle *t*, and the other half by the (invisible) capstan screw, which we will call *a*, or end-screw; then turn the instrument back again to its first position, and see if the level stands true; if not, repeat this operation till it does, correcting one half of the error by the equatorial handle, and the other half by the screw *a*. The declination-axis will then be parallel to the level, and both of them to the horizon. It must be remarked that in this operation it will be necessary to move the declination-circle round its own axis a little, in order to bring the same side of the level up-

permost;

## EQUATORIAL.

permost; but this in no degree affects the result, for the imaginary line, round which this axis revolves, is what is meant all along by the axis, and is the line to which the parallelism of the level is referred.

The declination axis remaining in an horizontal position, with the level above the axis, as in the *fig.* turn the declination-circle  $180^\circ$ , *viz.* till the level become below the axis; then, by means of the pinion for this purpose, restore the tube of the level to an upright position, and see if the bubble stand true; if not, correct  $\frac{1}{2}$  the error by the side screw, and the other  $\frac{1}{2}$  by *a*, the end screw. Now turn the declination-circle  $90^\circ$  each way from its last situation, and repeat the examination of the bubble, and correct as before,  $\frac{1}{2}$  by the side screw, at the opposite end of the tube, at right angles to the other side screw; and  $\frac{1}{2}$  by the end screw, near the side screw in question; and if after all these corrections in every part of an entire revolution of the declination-circle round its axis, and of the level round its axis, the bubble stand true, it follows that the axis of the declination-circle, and of the level, are in every direction parallel to each other, both of them to the tangent of curvature, in the middle of the level, and all three to the horizon. This adjustment is therefore complete.

It remains to be seen whether the line of sight of the telescope be at right angles to the declination-axis, and the latter to the polar axis.

Take the error of the collimation of the telescope in right ascension, by a star in the equator, *viz.* let the transit of a star on the equator over the assumed meridian be observed with the declination-circle turned towards the east, and also towards the west. If there be any difference in these observations, it will denote double the error of collimation in right ascension, and half of it will be the deviation of the line of sight from a line at right angles, to the axis of the declination-circle, and is correspondent to a similar adjustment of a transit instrument. The amount of this error being thus ascertained, let it be corrected by the screws, at the eye-end of the telescope, that move the wires to the east and west. The declination-axis, by means of its level being restored to an horizontal position, let the centre wire of the telescope, (by which is always understood the line of collimation,) be brought to bisect the meridian mark, by means of the sliding plate, and adjusting screw, below the polar axis; the telescope will then become a complete transit instrument; for, by the first operation, the declination axis is made parallel to the level and its axis, and both to the horizon; by the second, the line of sight is put at right angles to this axis; and, thirdly, it is adjusted to the meridian.

Now, let the error of collimation in right ascension in the same manner be observed with any star out of the equator, by a circumpolar star, (the nearer the pole the better,) suppose the pole star. If any difference in minutes and seconds of a great circle, as ascertained by the micrometer, should be noticed in its passage with the circle east or west, halve that difference, and it will be equal to the angle that the plane of the declination circle makes with the polar axis, if the observed star were actually in the pole; if not, divide it by the sine of its declination, and the true angle of the plane of this circle, (or of the line of collimation,) with the polar axis will be had. Again, if this operation be repeated with any other stars, and the error so found be divided by the sine of their declination, the error of the plane of the declination circle at the pole, *viz.* its greatest error, or angle with the polar axis, will be had. And note, if these observations are made with stars on each side of the equator, these quantities will be had in opposite directions. Finally, the same may be done by two land objects, one to the north,

and the other to the south, the north and south meridian marks, for instance, proper consideration being had to their declination; by this means the error will be thrown in contrary senses or doubled, and from a variety of such results a very correct mean quantity may ultimately be deduced; and when found must be corrected by the screws at one end of the declination axis.

It has now been seen, that, 1st, the level and its axis are parallel to the axis of the declination circle: 2dly, the line of sight is at right angles to this axis, and parallel to the polar axis; and, consequently, the declination axis is at right angles to the polar axis: 3dly, the polar axis parallel to that of the earth. These are the chief requisites in the adjustment of this instrument. Those that remain are secondary, and we shall take them in the following order: 1st, the adjustment of the cross wires to the focus of the telescope: 2dly, the hanging level: 3dly, the line of collimation north and south, as well as eastward and westward: 4thly, the index wires in the microscopes: 5thly, the refraction apparatus: and, 6thly, the power and scale of the microscopes.

First, *the cross wires.* Let the eye-tube be adjusted to distinct vision for parallel rays by some distant object, such as Jupiter, Saturn, or Venus, by day-light; that done, observe, while one limb of either of these planets appears running along the equatorial wire, whether any motion of the eye, upwards or downwards before the eye-glass, alters the relative place of the image and the wire; if a motion of the eye upwards moves the planet in the *same* direction; the wires are too near the eye-glass, and must be pushed in; and *vice versa*, till the image becomes fixed upon the wire, whatever be the motion of the eye. When this point is obtained, the eye stop, with its wires, must then be fixed, for that is their true place, *viz.* the correct focal point of the object-glass; and whatever indistinctness may be found from the diversity of eyes of different observers, must be corrected by the motion of the eye-glass only. Another point to be secured is the permanency, as far as may be, in the position of the object-glass; for if this be not correctly centered, which is very rarely the case, and, indeed, never to be expected, that is, if its axis be not concentric with the axis of the cell, in which it is fixed, any motion of this latter, by screwing or unscrewing it, may not only change the place of the focus to which the wires are adjusted, but will necessarily move the line of collimation both in right ascension and declination. To obviate this, therefore, two corresponding marks should be made with a graver, both upon the cell into which the glass is burnished, and also upon the tube of the telescope into which the cell is screwed, or otherwise inserted, that in case the object-glass should ever be taken out to clean it, &c. it may be restored very nearly, if not exactly, to its former position.

The eye-glass, object-glass, and wires being thus settled in their respective places to each other, it will not be an improper time to measure the interval between the wires, which cannot be too accurately done, being of such constant use; this may be either, 1st, by observing the passage of a star in the equator, and making proper allowances for the rate of the clock, or by a star out of the equator, and making proper allowances for the declination in the proportion of the radius to the cosine, or, 2dly, by means of the equatorial circle, and a fixed land object; and here the quantity must be diminished in the same ratio as the radius to the sine of the polar distance. We have made use of both methods as a confirmation of each other, and find the interval, which is equal in the three wires of my telescope, to be  $7' 34''.5 = 30''.3$  sidereal time; and these  
three

## EQUATORIAL.

three wires divide the diameter of the field very nearly into four equal parts.

Second and third adjustments: *the hanging level.* By means of its proper handle *u*, move the declination circle about its axis, till the bubble of the hanging level *l m* rests true between the indexes; there fix it by the clamp *w*, reverse the level by taking it out of its pivots, and turning it end for end; if the bubble now stand true, the level is adjusted; if not, correct  $\frac{1}{2}$  the error by the declination handle, and the other  $\frac{1}{2}$  by the small screw at the bottom of the level; then reverse the level and repeat this operation till it does. The level, or rather a tangent to its curvature at its middle, will be parallel to the axis on which it swings, and both will be horizontal. At this time look through the telescope, and see what land object is covered by the horizontal wire; now invert the telescope by turning it  $180^\circ$  round the declination axis, and  $180^\circ$  round the polar, and bringing the level true, it will then point to nearly the same place; and if exactly the same object as before be now covered by the horizontal wire, the axis of the level is adjusted parallel to the line of collimation in a vertical direction, if not, correct half the error by the little capstan screw at the bottom of the cock, or arm, that supports one end of the axis of the level, and the other half by the declination handle; invert the telescope, and repeat the operation, till the same object is covered in both positions, and the level is found true, then will the level and its axis be parallel to the line of collimation, and the object covered by the wire may be concluded to be in the horizon.

Fourth. *The index wires of the microscopes.*—The line of collimation, with respect to east and west, has been already adjusted as above. Let then the declination axis, by its level, be restored to an horizontal position; at this time adjust the index wires in the two equatorial microscopes *W, X*, to bisect the two opposite divisions  $360^\circ$  and  $180^\circ$ , then will these wires be rectified to their proper place. That being done, bring  $90^\circ$ , or the division that represents the equator on the declination circle, under its respective microscope, and turn the whole instrument one quarter round on the polar axis, *viz.* till  $90^\circ$  on the equatorial circle be bisected by the micrometer; and, if at this time the bubble of the hanging level appear true, the index wire of the declination microscope is correct; if not, correct  $\frac{1}{2}$  the error by the declination handle *u*, and  $\frac{1}{2}$  by the little screws at the side of the hanging level, then reverse the telescope, *viz.* turn it till  $270^\circ$  on the equatorial circle come under the micrometer wire, and if the level then rest true the adjustment is complete; if not, repeat the operation, as before, till it does; then by its proper screw bring the index wire of the declination micrometers to bisect the points  $90^\circ$  and  $90^\circ$ . The indexes of both circles will be then adjusted, and the axis of the hanging level brought parallel to the line of collimation, with respect to east and west, as well as with respect to north or south. Note, this parallelism of the axis of the level, to the line of collimation in a direction east and west, does not appear to be a very important rectification, but on some occasions may have its use.

Fifth. *The refraction piece.*—After what has been done, this apparatus will be adjusted. Bring the telescope, by means of its two levels *P k*, and *l m*, to point to the horizon, and in the meridian; then by the two points, *f, b*, Plate XI. fig. 2, of the refraction piece, bring its two levels *e* and *g* to rest true; move the nonius *d*, of the little semicircle of the horary and vertical angles, *a, b, c*, to the middle of the divisions, or  $0^\circ$ ,  $0'$ , and also that of the little quadrant of altitude, *l k*, to  $0^\circ$ ,  $0'$ , and this part is adjusted.

Sixth. *The microscopes.*—The magnifying power and scale of the microscopes is all that remains to be considered. The magnifying power of a compound microscope, as is well known, depends on the proportion between the distance of the object, and of its image from the object-glass, together with the proportion between the focus of the eye-glass and the ordinary focus of the eye looking at a small object (suppose) of  $\frac{1}{10}$ th or  $\frac{1}{15}$ th inch. These two ratios compounded give the power of the microscope. The former is called magnifying by distance, and is a material part in the construction of these microscopes; the scale of the micrometer being regulated by this part of the magnifying power. For example, let the distance of the object from the glass be = 1, and the distance of its image = 4, its power will be 4; and consequently the scale of the micrometer or motion of its screw, to answer to  $10'$ , (suppose) must be 4 times as great as the space occupied by  $10'$ , on the limb of the circle; and if the radius of the circle be two feet, an arc of  $10'$  will be equal to 0.07 inch nearly on the limb, and = 0.28 inch on the scale, *viz.* = to the same arc on a circle of 8 feet radius: and if each revolution of the micrometer screw be intended to describe  $1'$ , the screw must contain about 35 threads in an inch. But as it would be difficult to adjust the screw exactly to the scale, the advantage of the construction of these micrometers is, the scale may at any time be adjusted to the screw; for let the interval between any two nearest divisions =  $10'$  on the limb, be measured by the screw, and, suppose, instead of being =  $10'$  or  $600''$ , it appears only =  $570''$ ; it is evident that the scale is bigger than it should be, or, which is the same thing, that the image is less by  $\frac{30}{600}$  or  $\frac{1}{20}$ . In this case, increase the distance between the micrometer wires and the object-glass =  $\frac{1}{20}$ , by unscrewing or drawing out the tube that carries the micrometer and eye-glasses, and the scale is adjusted. It will, at the same time, however, be right to readjust the object-glass of the microscope to distinct vision, by the screw of the cell that contains it, until the image and the wires have no relative change of place by any motion of the eye. This will again occasion some small alteration in the scale, and must be corrected by repeated trials, and the scale adapted to the divisions on the arc; and if the moveable wire of the microscope be now brought to coincide exactly with the fixed one, and the moveable index brought to zero on the screw-head, the micrometer is completely adjusted. This having been done with all the microscopes, and the opposite ones being made to agree, each with the other, in such manner, that the fixed wires may become a correct diameter, the whole instrument will have been completely adjusted.

Before taking an observation of right ascension and declination, the telescope must be adjusted to the meridian mark, so as that the centre wire may exactly bisect it, in which situation care must be taken to make the index wires of the equatorial micrometers bisect the points of  $360^\circ$  and  $180^\circ$ , by means of the adjusting screw of the polar axis; and when an observation is made out of the meridian the altitude and angle of the horary and vertical circles must be taken by the refraction apparatus; then with these arguments, the refraction and parallax, in north polar distance, and in right ascension, may be found by inspection in the subjoined tables, by which any observation may be readily reduced to the meridian.

In this account of sir George Shuckburgh, the reader may have observed, that the order of the adjustments proposed is not that which is best in practice; as some of the leading adjustments must necessarily be deranged by the subsequent ones as he has described them, and indeed so as to

## EQUATORIAL.

tender new adjustments necessary; but we were unwilling to transform the baronet's directions that have met with the approbation of the Royal Society, though we cannot dismiss the account without this remark for the reader's consideration; *viz.* the rectification of the telescope, levels, &c. ought certainly to precede the adjustments of the circles, that depend on their accuracy of position.

*The Armagh equatorial instrument by Mr. Ed. Troughton.*—The instrument which now claims our attention is represented in *Plate XVI. of Astronomical Instruments*, and, though similar to its predecessor shewn in *Plate XV.*, as to its use and properties, yet forms a striking contrast with it, in regard to compactness and beauty; too evident a contrast indeed to be overlooked at the first glance of comparative inspection. The arrangement of its principal parts is so novel, and at the same time so natural, as well as the connection of its smaller ones effected with such symmetrical precision, that the mind is struck with the contemplation of it, and spontaneously considers it as an instrument of a superior order, that seems to place at a distance every other individual of its kindred: we therefore feel a peculiar pleasure in concluding our article with the account of an instrument, which, though it comes last, ought in our estimation to stand first, as a model for future imitation. As the different component parts of the equatorial instrument are now become familiar to the reader, who has perused the preceding descriptions, we shall satisfy ourselves with a brief detail, unaccompanied by alphabetical references to the drawing, which presents a perspective view of all the leading features.

The horary or equatorial circle, without centre or radii, occupies the middle part of the instrument; and is held in its proper place by eight conical tubes of brass, four above and four below, which converge respectively towards the upper and lower poles, and which stand at the distance of a quadrant from each other. A strong and light frame is thus formed of the shape of two similar cones joining their bases at the horary circle, and connected near their summits by two pieces of metal that terminate each with a hollow cylinder of about two inches diameter; this frame is further braced by cross connecting tubes, as well as by side braces, or props, in the manner sufficiently explained by the figure; and the whole frame, thus firmly united, supplies the place of a revolving axis, and carries the horary circle round with it, when it is made to turn on its cylindrical pivots. On these pivots the horary circle was finally turned true, after the frame was united and made fast in all its parts, so that the eccentricity of the circle, if it had any previously, was done away, by being turned on its own pivots. The inferior end of the polar axis or frame is supported by a solid stone, about 30 inches above the floor, with which it has no connection to produce unsteadiness; this stone is capped by an apparatus of strong brass work, in which is produced the adjustment for bringing the instrument into the plane of the meridian, as well as that for giving the polar axis its proper elevation. This lower end of the axis terminates in a hemispherical button of hardened and finely polished steel, which presses endwise against a plane of agate, and is kept central by two rollers that form an angle to receive it on the lower part of the apparatus; all which contrivances may be readily conceived without more minute description. The support for the elevated pole consists principally of a stone pier, reaching from the ground to the centre of the instrument; but on it is firmly fixed a strong frame of wrought iron, so constructed as to turn its edges towards the telescope hereafter described, in every direction; otherwise it would obstruct

the field of view in elevations below the upper pole. The upper gudgeon is received between two rollers similar to those below, except that these are perforated, as well as the gudgeons, in order that as little light as possible may be intercepted when the telescope is pointed to the pole. At about six feet distance from each other, in the east and west line, upon the same solid foundation that supports the bearing stone and pier, are firmly fixed two pillars of stone, each nearly three feet high; and on the tops of these are placed fast two strong cones of brass to support the microscopes for reading off the horary angles. The length of these two cones of brass is so proportioned as to correspond to the effective length of one half of the frame, or polar axis, in its inclined state, in all changes of temperature, by which means the microscopes preserve their relative situations at the horary circle. This circle is divided into 5' spaces, or spaces of 20 seconds of time, upon its extreme or exterior edge, which was made broad for this purpose, and the heads of the equatorial micrometers are so divided as to subdivide the said spaces into tenths of a second of time. The axes of the microscopes of course are horizontal. At the tops of the conical parts of the pillars are adjustments for moving the microscopes; one with respect to perpendicular height, another with respect to the distance of the exterior edges of the horary circle, and a third along its plane. An apparatus also for quick or slow motion is attached to each of the cones in question, by means of which the instrument may be securely fixed, either in the meridian, or in any other given position, as it regards the meridian. The declination circle likewise occupies the middle of the frame, and has its centre precisely in the same point that is the centre also of the horary circle, these two circles being concentric, but having their planes exactly at right angles to each other, after the manner of the meridian and equatorial circles of a common ring-dial, when put into a state for use. The declination circle is double, or composed of two complete circles united in several places by connecting pillars, and having each eight radii also connected in the same manner, after being inserted into the common axis, which is of the shape of a double cone. The telescope passes through the bases of the united cones of the axis, and has an aperture of  $2\frac{2}{3}$  inches, consequently the connecting pillars are long enough to admit such a telescope between the united circles, in which situation it is not very easily distinguishable in the figure. Its eye-piece, however, is discernible just under the declination circle. It is 44 inches long, and revolves within the horary circle; consequently requires a diagonal or reflecting eye-piece when directed to the equator, in which situation the aperture admits light enough, notwithstanding the interposition of the horary circle. When the elevation is great, the head of the observer must necessarily be admitted between two out of the four lower conical pillars of the frame, which circumstance points out the scale of magnitude on which an instrument of this construction ought to be made, to be useful at all degrees of elevation of the telescope. The telescope has various magnifying powers, which may be used according to circumstances. Two opposite quadrantal arcs of the horary circle have chord-bars parallel to each other, at the middle points of both which are sockets for the gudgeons of the declination axis to work in as their supports; which bearings made the braces of the frame and horary circle essentially necessary to give strength and firmness to the whole. The declination axis, which is about three feet long, has an adjustment at one end for setting it at right angles to the polar axis, and carries also a very sensible spirit-level parallel to itself; with another of which

the telescope is likewise furnished, which it cannot be necessary to particularize further, after our former descriptions of spirit-levels, except that in those the adjustment screws had divided heads, whereas in these there are divided scales of ivory, by means of which the half differences can be accurately estimated to the *fraction of a second*. The declination circle is divided into spaces of 5', which are again subdivided by the microscopic micrometers into minutes and single seconds. One of these microscopes is seen above the horary circle and the other below, but both are supported by it, and point horizontally to opposite points of the declination circle, as one of the others is seen at the top of one of the pillars pointing to the exterior edge of the horary circle. The apparatus for quick or slow motion, to govern the declination circle, is attached to the lower part of the frame, or polar axis, as represented in the figure. The excellence of this instrument has been fully established in public estimation, by the use that has been made by Mr. Pond of the Armagh observations, taken with it in 1797, when he formed his catalogue of some of the principal stars, as we have already stated; in which catalogue (see our article DECLINATION,) it will be seen that the accuracy of its measures accord very nearly with the results derived from an average of the best modern instruments: and we may add, that the coincidence would doubtless have been still more remarkable, had not the divisions, which are by dots, been injured by an accident. An intense frost, to which the instrument was exposed at the top of the maker's house, covered it with black spots, and corroded its surface so as almost to obliterate the dividing points, which were necessarily enlarged by hand, and of course might be altered a little by this manual operation, however carefully performed. The divisions of the other circle met also with an accident at the other side of the water, which, though of a different nature, has rendered the divisions less correct than they were at first. Besides which, two other circumstances ought also to be named as drawbacks in this instrument, when compared with the circular instruments with which it has been contrasted, namely, its verifications were not made with a plumb-line; and its polar position may be considered as somewhat unfavourable for taking declinations with the utmost nicety; but notwithstanding all these deductions, the accurate performance of the instrument has stood the test of a rigid comparison with the instruments of three modern observatories.

*Adjustments.*—1. Turn the *wire-plate* round, if necessary, so as to make the middle vertical wire continue, throughout the whole field of view, on some distant and well defined point, while the telescope is elevated or depressed as it turns on the axis of the declination circle, to which the wire will in that case be perpendicular.

2. Slide the *object-glass* of the telescope in or out, while you view a star of the second magnitude, until the parallax of the wires is taken off, that is, until the vision is as distinct as possible.

3. To adjust the *level* of the *declination axis*. By the motion round the polar axis bring the bubble of the level to the middle of the tube, and in this situation make its scales or indices to coincide with both its ends; turn the level, end for end, and if it now stand in the middle, as before, the axis is level; if not, alter one half of the deviation from the truth by a slight motion round the polar axis, and the other half by the screws of the level itself; and repeat these rectifications till the bubble will stand always in the middle of the tube when its ends are reversed. But the bubble of a hanging level may also require a lateral adjustment; to examine it in this respect, turn it round on its

own axis a little, and if the bubble has a tendency to go to either end of the tube it must be rectified by the side screws till this tendency is removed, and then if the bubble will yet bear reversing, the level is properly adjusted.

4. To adjust the *pivot-holes* of the level *parallel* to the *axis* of the declination-circle, and the *axis horizontal*; bring the bubble of the level to the indices on the tube, with the level above the axis, by moving the instrument round the polar axis; then turn the declination-circle half round till the level is under its axis, and if the bubble now settles to the middle, as pointed out by the indices, the level is right; if not, alter one half of the error by turning the polar axis round, and the other half by the two screws that govern the pivot-hole; in the next place turn the telescope 90° round the declination-axis, and by the screws that govern the other pivot-hole, bring the bubble to the indices, and the axis will be horizontal, as well as the pivot-holes parallel to it in all directions; for when the level itself is adjusted, as above directed, it is evident that if the bubble keeps its place at the indices during a revolution of the declination-circle, the axis itself must necessarily be horizontal.

5. To set the *declination-axis* at *right angles* to the *polar axis*, we may use the level itself instead of the declination-axis, after it has been set parallel thereto as just directed; for this purpose, bring the bubble to the indices by moving round the polar axis, and bisect opposite points of the equatorial circle by the two wires of the microscopes; turn the instrument exactly half round by the help of the microscopes so adjusted, and if the bubble now settles to the indices, the two axes are at right angles to each other; if not, alter one half of the error by the slow motion of the polar axis, effected by the equatorial tangent screw, and the other half by the two screws at one end of the declination-axis adapted for this purpose.

6. To set the *line of collimation* true in *right ascension*, let the bubble be brought to the middle of the tube, or to the indices as in the last adjustment, and look at any well-defined small object near the horizon, as bisected by the middle vertical wire; then having noted this mark, turn the instrument half round the polar axis, as indicated either by the level or equatorial microscopes, which are now adjusted to do the same thing; and when the telescope is turned back round the declination-axis, note if the same object or mark be intersected as before, if not, alter one half of the deviation by the equatorial tangent screw, and the other half by moving the wires of the eye-piece in the telescope; thus when the same mark is bisected by the middle vertical wire, in reversed positions of the telescope, the line of collimation will be right with respect to right ascension.

7. To place the *indices* of the declination-circle to read *polar distances* truly. Before we describe this adjustment, it may be proper to remark, that the microscopes themselves of this circle have each three separate adjustments, the first, that which alters the power by altering the distance of the object lens, so as to make one minute on the circle equal to a revolution of the micrometer screw; the second, that which produces distinct vision by varying the distance of the entire microscope from the divisions of the circle; and the third, that which places zero on the scale of minutes to agree with zero on the declination-circle, and also zero on the scale of seconds, to agree with zero on the scale of minutes, as effected by the head of the micrometer being made to turn independently of the screw. These minor adjustments being understood, point the telescope to any distant land object, and let the middle horizontal wire bisect it, and read off the polar distances shewn by the indices, and take half their sum; make

## EQUATORIAL.

the same observation when the instrument is turned half round the polar axis, and take another mean of the angles now shewn by the opposite indices; subtract the former mean from  $180^\circ$ , and add the difference to the latter mean, and *half of this sum* is the angular distance from the pole of the instrument, to which quantity the indices must be put within the exactness of a minute or so, as this process must hitherto be considered as an approximation only: repeat the operation we have described of obtaining two means of polar distances more accurately by using the scales of minutes and seconds; thus, read off by the indices the quantity to the division next below the sub-divisions to be measured by the scales; then turn the micrometer head till the wire of the microscope bisects the next following point, taking care to count the notches passed over as minutes, and the seconds and parts on the micrometer scale to be added to the quantity given by the indices alone; and the *supplement* of the mean of the two measures by the microscopes, added to the mean read off in the same way, when turned half round the polar axis, being divided by two, will give the *true* angle from the pole of the instrument; and the scale of minutes, as well as scale of seconds on the micrometer head, must be finally adjusted thereto.

8. To place the *declination-level parallel to the line of collimation* of the telescope, bring the declination-axis level, or nearly so, and let the bubble of the declination-level be brought to the middle of its tube, by the motion round the

polar axis, and let the indices be put to its ends; turn the level a small quantity round its own axis, and try if the bubble has any tendency to either end; if it has, adjust it laterally by the screws that move one of its pivots sideways, till it is right in this respect; now reverse the level, and if the bubble does not stand in the middle, alter one half the error by moving the telescope in declination, by means of its screw for slow motion, and the other half by the screws that govern the pivots of the level, and the level itself will then be adjusted. In this situation of things look for some object in the centre of the field of the telescope, and note it; turn the instrument half round the polar axis, and as much round the declination-axis as to bring the telescope exactly to the same object again; if the bubble now stands in the middle, the adjustment is right, but if otherwise, one half of the error must be altered by the motion of the telescope in declination, and the other half by altering the pivot-hole of the level. Lastly, turn the instrument the space of *six hours* round the polar axis, and adjust the other pivot hole till the bubble stands in the middle of its tube, and the adjustments are all complete, provided the polar axis of the instrument be exactly parallel to the axis of the earth, which we have all along taken for granted, and which may be effected by its own adjustments as pointed out by an observation of a circum-polar star, agreeably to our directions given under our article *EQUATORIAL Sector*.

## EQUATORIAL.

### *Explication and Use of the Tables.*

The three first tables are particularly calculated for the use of a large equatorial instrument, for the purpose of clearing observations made with it from the effects of refraction and parallax, when neither Dollond's refraction apparatus is used, nor the micrometer circle of Ramsden's for adjusting the wire used in taking altitudes; but the four last are adapted more peculiarly for portable instruments. They are copied from sir George Shuckburgh's account in the Philosophical Transactions, and, being adapted for all latitudes, are a suitable appendage to the descriptions we have given of the different instruments.

Table I. gives the correction of the refraction in north polar distance, by entering it with the altitude at the top, and the angle of the horary and vertical circles on the left hand side; and in the common point of meeting is found a quantity in seconds and decimal parts, that is in all cases to be added to the apparent polar distance to give the true; but if it be entered with the angle of the horary and vertical circle in the right hand column, it will give the refraction in right ascension, by multiplying the quantity here found by the secant of the declination to be found in Tab. IV., which is a readier operation than dividing by the cosine, and amounts to the same thing.

Table II. gives the effect of the sun's parallax in right ascension and north polar distance, and is to be entered with the same arguments as Tab. I.; and the parallax in right ascension is to be multiplied by the secant of the declination as before; the sun's horizontal parallax being assumed = 8".6.

Table III. is a similar table, only calculated to an horizontal parallax of 10"; so that whatever be the parallax of the sun or planets, this correction may readily be found, almost by inspection, viz. by multiplying the tabular number by the exact quantity of parallax of the body observed, and cutting off the decimal quantity.

Table IV. contains the natural secants to each degree, extracted from Sherwin's tables, to be ready for the operations required above.

Table V. gives the correction of the time; viz. of the sun or star's distance from the meridian, as ascertained by a portable instrument not previously adjusted to the meridian; this quantity also is to be multiplied by the secant of the declination.

Table VI. gives the correction of the meridian line in minutes and decimals, which may be near enough for portable instruments; but the quantity here found must be multiplied by the secant of the altitude.

Table VII. (like Table I.) is adapted to seconds of time, and gives the refraction in right ascension in terms suited to such instruments as have the equatorial circle divided into hours and minutes.

Table VIII., in like manner, gives the refraction in declination. The arguments are the same in all the tables.

These tables were constructed by sir G. S. in the year 1774, for his own use, and were founded on the principles explained by the Hon. S. M'Kenzie in fig. 4. of Plate XIII., where I F is a portion of a vertical circle = the refraction in altitude; C F a parallel to the equator; I C a portion of an horary circle = the refraction in declination, found by Tab. I. and Tab. VIII., the angle C I F, the angle of the horary and vertical circle; C F the refraction in right ascension, found by Tab. I. and Tab. VII.; D I (a parallel to the horizon) the correction of the meridian, found by Tab. VI.; and D F the correction of the time, found by Tab. V.; and as I F will hardly ever be found to exceed 30', these triangles have been considered all as plane; making due

allowance, in the proportion of the sine to the radius, for the distances of the arcs D I, F C, and D F, from their respective poles, which has been noticed at the foot of each table. The refraction in altitude was taken from Mayer's Tables, 1770, London; which is calculated for a density of the air expressed by 29.6 inches of the barometer, and 50° of Fahrenheit's thermometer.

EQUATORIAL Micrometer, is an apparatus applied to a telescope, that has an equatorial motion, for the purpose of measuring small differences of right ascension and declination of any two heavenly bodies, that pass either successively, or at the same time nearly, through the field of view, so as to be both visible at the same elevation of the telescope. This method requires no graduated circles with verniers or compound microscopes, and yet is capable of great accuracy within certain limits of difference between the relative situations of the bodies to be compared together; and if the right ascension and declination of one of the two observed bodies be previously known with sufficient accuracy, the place of the other can be determined therefrom by the observed differences. The common wire micrometer has been long in use as an appendage to the eye-piece of a telescope, and was used by Dr. Bradley in making astronomical observations, his manner of doing which was communicated to the Royal Society in the year 1772 (vol. lxiii.) by Dr. Maskelyne; but as the telescopes then in use were from ten to fifteen feet long, for want of the achromatic object-glasses, an equatorial motion was given, not from one centre, but by means of supporters at each end of the wooden tubes, so contrived as to be manageable both in altitude and azimuth; which apparatus is still preserved at the Royal Observatory. The wires of the micrometer have been adapted differently by different makers, some making only one moveable, and some more; but they all agreed in placing them in the focus of the eye-piece of the telescope. It is not, however, our intention to enter into a detail in this place of all the different constructions of the micrometer, as applied to various purposes, but to confine ourselves to a notice of those that have been more particularly applied to telescopes having an equatorial motion. For the other constructions, we refer to the article MICROMETER.

Soon after the discovery of the properties of the achromatic object-glass of a telescope had reduced the length of the astronomical telescope to a portable size, without diminishing either its power or size of its field of view, not only were equatorial instruments contrived of various constructions, as we have already described, but equatorial stands for simple telescopes were invented, and continue to be in use with the best telescopes to the present day. To these telescopes the micrometers are a very necessary and useful appendage, inasmuch as they render it capable of being applied with advantage in ascertaining the right ascension and declination of a comet, planet, or other body out of the meridian, when they happen to be near enough to a known body to admit of being taken into the same field of view without altering the elevation. Though the wire micrometer was first invented, as applied to the focus of the eye-piece, and continues to be used in many instruments, yet since the invention of the achromatic object-glass, Dollond's object-glass micrometer has by some astronomers been preferred, or at least deemed equally useful, particularly when the cross wires are also used in conjunction, as described by Dr. Maskelyne in his paper on this subject read to the Royal Society of London on Dec. 12, 1771, which was the year after Smeaton finished his wire micrometer, that had been begun about forty years before. If we give

## EQUATORIAL.

an account of these two kinds of micrometers in succession, the reader will perceive the varieties that may arise from them by slight deviations of construction. We will begin with Smeaton's, as being of prior origin:

We are not aware that Mr. Smeaton has left behind him any perspective drawing of his equatorial micrometer, though we have heard that there is an undescribed sketch of one among his papers, at present in the possession of Mr. Lloyd; but there is a section of one accompanying his paper read to the Royal Society of London on June 7, 1787, which is sufficient for explaining the principle of its application. *Fig. 3. of Plate XIII. of Astronomical Instruments*, is the said section, as viewed from the eye-end of the telescope. "This micrometer," says the author, "is furnished with five horary wires, denominated in their order, *a, A, B, C, D*, (*B* being the middle horary wire,) and the two declination wires are denominated *A, B*, each moveable by a separate and independent micrometer-screw, from the outside of the field to the centre, and a little beyond it; so that each wire can be moved into the place of the other, when at or near the centre." The field of view was only  $1^{\circ} 17'$ , and the magnifying power as low as 20, with an eye glass of  $1\frac{1}{2}$  inch focus, and a double object-glass of  $34\frac{2}{3}$  focal length; notwithstanding the author calculates that a difference of only  $2\frac{1}{4}''$  may be read by such apparatus, which he concluded was near enough for any instrument to read out of the meridian. In the construction of the stand every thing was done to ensure stability of position at any given elevation, and the frustum of an hexagonal stone was used as a pedestal, detached from the floor of the observatory. With an apparatus so steady, it was not necessary to confine the observations to two bodies, to be compared, whose difference of right ascension was only a few minutes, but even hours could be admitted of for the interval of the successive transits, provided the difference of the declinations did not exceed the interval between the two adjustable cross wires. The difference of the right ascensions was easily ascertained by a regulator or chronometer, measuring the interval between the transits, and the distance between the bodies as measured by the interval between the cross wires, gave the difference of the declinations. The first trial of the steadiness and accuracy of this apparatus was made with Saturn and  $\gamma$  Capricorni, from which it was found that the star had the same right ascension and declination, determined on two separate evenings, at the distance of 48 hours, though the instrument had not been touched during the interval. But the principal observations noticed in the memoir, are those relating to the elongation of Mercury, as taken from Sep. 23, to Oct. 13, 1786, the result of which was, that at  $5^{\text{h}} 22^{\text{m}} 35'$  mean time on Sep. 23, A.M. Mercury's right ascension, deduced from a comparison with  $\alpha$  Orionis, was  $163^{\circ} 59' 21''$ , and his declination north  $7^{\circ} 44' 25''$ . For the particulars of the calculations and the tables of the observations, see the *Phil. Trans. of 1787*. Also for the manner in which a simple telescope may be made to move in an equatorial direction, see our article *Equatorial Stand of a telescope*.

The object-glass micrometer of Dollond, of his most improved construction, is represented by *fig. 4. of Plate XII.* agreeably to a drawing given in Mr. Dollond's pamphlet that accompanies his equatorial instrument. By the improvement, says the author, this micrometer has received, it is rendered capable of being applied to telescopes of small aperture; the focal length of the object-glass being considerably increased, the scale by which the angles are measured is much enlarged. By this increase in the focal length of the object-glass of the micrometer,

the perfection of the telescope is less injured; but the greatest advantage that is derived from the improvement, is the length of the segments, which admit of the whole aperture of the telescope, even in measuring the largest diameters of the sun or moon, and the object retains the same brightness in measuring the largest angles as in measuring the smallest.

Notwithstanding these several advantages, the instrument is greatly reduced in size, as will appear by inspecting the figure representing the micrometer on the end of the telescope; the description of which is as follows:—

*a* and *b* are two long segments of an achromatic object-glass, divided into separate pieces by a diametrical line, and fitted into separate frames, so that by sliding one or both the segments, they may be made to form in effect either one object-glass or two, it being the property of half a well ground glass to give as distinct an image as the whole would do; the segment *a* is moved by turning the milled head *c*, and the segment *b* is moved by turning the handle *d*. When an observation is to be made, it is generally known what number of minutes the angle will contain nearly; suppose, for example, the diameter of the sun were to be measured, which is known to be about  $32'$ ; move the segment *a* till the index *e* comes to 32 on the scale *ff*, then looking through the telescope, move the segment *b*, by turning the handle *d* till the circumferences of the two images, formed respectively by the two segments, are brought to touch one another externally, and the quantity that the segments have moved will be measured by the scale *gg*, and vernier *b*, by which an inch is divided into five hundred parts: the greatest exactness is required in this scale, as the angle is absolutely to be determined by the measure taken with it; the scale *ff* being only of use to set the segment *a*, so that in measuring the angle by moving the segment *b*, they may be both moved nearly the same quantity.

The handle *i* is to turn the micrometer round, to bring the line dividing the two segments of the object-glass into the plane passing through the two objects, whose distance is to be measured. It is necessary, in making observations with the micrometer, that the telescope, when the micrometer is on, be adjusted to the *most perfect vision* of the object to be observed, as a small error in this respect may occasion a considerable difference in the observation. To find if there is any error in the adjustment of the micrometer scale *gg*, turn the handle *d*, so as to make the two images perfectly unite, and the number shown by the scale and vernier will be the error of adjustment, if there is any; this error may either be allowed for in the observations, or be corrected by the vernier screws at *k*. The object proper to be used for adjusting the focus of the telescope with the micrometer on, may be any of the celestial bodies, or some distant well defined land object; but for adjusting the micrometer scale, the object may be nearer, such as a printed paper at two or three hundred feet distance, provided the focus be first well adjusted to this object. A table is usually given with the micrometer, which shews the number of minutes and seconds answering to the divisions on the scale. When the micrometer is on the end of the tube of the telescope, it is necessary that the screw at the centre of motion be tight, otherwise, which is better, that there be a counterpoise at the eye-end to preserve the equilibrium in any elevation. Also, as the object-glass of the micrometer is concave, the common focus of the object-glass of the telescope end of it is lengthened, which circumstance requires the tube of the eye-glass

## EQUATORIAL.

to be longer than when the telescope is used without the micrometer.

The properties peculiarly ascribable to the two kinds of micrometers we have described are, that the one at the focus of the eye-glass is adapted for measuring the differences of right ascensions and declinations of two bodies, one of which has its plane known; but the one placed at the object end of the telescope is calculated, by means of its graduated scale, to measure absolute small distances; and the accuracy of its scale may be brought to the test by a comparison with a known interval between two stars or other distant bodies. Dr. Maskelyne, in the paper we have already noticed, has however shewn how, by the addition of two cross-wires in the focus, the differences of right ascensions and declinations may also be measured by Dollond's micrometer, thus: "Suppose it be required to measure the difference of right ascension and declination of two stars, whose difference of declination does not exceed the extent of the scale of the micrometer, and the distance of the meridians passing through the stars does not exceed the semi-diameter of the field of view, turn the wires about till the western star runs exactly along the cross-wire by the diurnal motion; then separate the two segments of the divided object-glass to a convenient distance, and turn the micrometer about, by means of its proper handle, till the two images of the same star, formed by the two segments of the object-glass, pass the horary or vertical wire at the same instant. Lastly, partly by the feet-screws of the stand, and partly by the handle that separates the segment, cause the southernmost image of the northernmost star, and the northernmost image of the southernmost star to appear both upon and run along the cross or horizontal wire: the numbers standing upon the scale of the micrometer will then shew the difference of declination of the said stars; and if the times be noted when they pass successively the horary or vertical wire, the difference of the two times will give the difference of their right ascensions also." (See Phil. Trans. vol. lxi. article xlix.) It was one of Dollond's object-glass micrometers, attached to an 18 inch reflecting telescope by Short, and another attached to a two feet reflector, that lieutenant (afterwards captain) J. Cook, of the Endeavour, and Mr. Charles Green; formerly assistant at the Royal Observatory, used in observing the transit of Venus over the sun's disc on June 3, 1769, in King George's island, or Otaheite, in the South sea, as recorded in the same volume of the Philosophical Transactions.

For an account of the history of the micrometer, and its various constructions by different artists and ingenious men, see the article MICROMETER.

**EQUATORIAL Sector**, an instrument sometimes used in *Practical Astronomy*. This instrument was invented by Mr. George Graham, F. R. S. for measuring greater differences of right ascension and declination of a heavenly body, as compared with another body, than the equatorial micrometer alone will give, and may be made of any convenient dimensions. One of these instruments made by Mr. Graham, is yet preserved at the Royal Observatory at Greenwich, and is occasionally employed to determine the right ascensions and declinations of a comet or other body out of the meridian, for doing which it is still found to be serviceable. Doctor Robert Smith has described the principle and construction of Graham's sector, in the year 1738, and Mr. B. Martin copied the account verbatim in his magazine, from one or other of which authors the different dictionaries have their description transcribed.

*Graham's Equatorial Sector.*—In justice to the contriver

of the equatorial sector, we propose to describe it agreeably to its original construction; but as we have copied the different parts of the drawings, as given by Dr. Smith, to be thrown into one perspective instrument, it becomes necessary to vary the detail accordingly. *Fig. 1. of Plate XIII. (of Astron. Instr.)* is a perspective view of the principal parts of the sector lying in its inclined stand or bed, which we have supposed to be firmly fixed to a sloping pedestal, exactly parallel to the earth's axis. This inclined bed, A B, is a strong brazen plate or bar, turned up at the ends in a perpendicular direction at C and D; the lower end C has a screw, entering it from below, strong enough to bear the inferior end of the sector's axis E F G, the conical hole made in the end of the latter at E, resting on the conical point of the former; the upper end D has a slit in it, into which the axis is demitted at the cylindrical part F, below the circular plate H attached to the axis. The whole length of the axis is 18 inches, of which the square part E F is 12. On the posterior part of the bent end D of the inclined supporting plate A B, is a clamp I, turning on two pivots, so that it may be elevated or depressed without turning round in an equatorial direction; this clamp fixes the circular plate H, in any given place on its edge from turning round, but adapts itself to the plate, so as to press equally on both surfaces, by means of its vertical motion on pivots; consequently the axis E F G, to which the plate H is attached, may have a motion like the polar axis of the earth when wanted, and may be firmly fixed by the clamp acting on its plate in any given situation. At the superior end G of the axis is fixed another circular brazen plate K L on one of the flat sides of the squared axis, and having a motion round a pin with screws and a tightening collar; on this plate a cross of brass is screwed fast, composed of four bars at right angles to each other, two of which bars constitute an inverted cock, on the bent parts of this the long radial bar M N is fixed, which is made strong by an edge-bar on its under side. Whenever, therefore, the circular plate K L moves round its central pin at G, the radial bar, carried by it, partakes of its motion, and *vice versa*; this plate has also a clamp O, similar to the clamp I in every respect, by which it may be made steady in any given situation. The length of the radial bar is  $2\frac{1}{2}$  feet, and its breadth at M and N  $1\frac{1}{2}$  and 2 inches respectively: at N is a small arch of a circle, 6 inches long and  $1\frac{1}{2}$  broad, graduated into  $10^\circ$ , and subdivided into quarters, that read and are figured both ways. Upon this radial bar is mounted a telescope P, of  $2\frac{1}{2}$  feet in length, moveable on the point M, as an axis of motion, near the object-end, and having a vernier near the eye-end with 16 quarters of a degree divided into fifteen equal parts, so as to read off exact minutes. This vernier is moved by the nut of an endless screw Q, that is adapted as an apparatus for fast or slow motion, in the usual way. The diameters of the two circular plates are each 5 inches, and the plates are strong enough to hold the telescope in any given position that an observed body may require.

The polar axis E F G of this instrument must be placed *truly* in the meridian and parallel to the earth's axis, which may be done by bringing the telescope parallel to the axis itself, and, after fixing it, by following a circumpolar star therewith, and noting the apparent path as it respects the intersection of the cross-wires of the telescope: the deviation above or below the cross-wire will point out the error of elevation of the axis, and the difference in the times of the star's passage through the two semicircles, east and west respectively, will discover the deviation from the meridian

## EQUATORIAL.

line; then half these errors may be corrected by the screws that fix the inclined bar *AB* to the pedestal, and the other half by altering the position of the telescope, till, after several successive trials, the star will accompany the intersection of the wires through its entire circle. It is necessary, however, that the polar axis be placed, by means of a small quadrant or other such contrivance, very nearly in its proper degree of elevation, as well as nearly in the meridian on the pedestal previously to the adjustment by a circumpolar star. It is also necessary that the line of collimation of the telescope be parallel to the plane of the sector, as well as the latter at right angles to the circular plate *H*, which represents the equator; the former may have its truth examined by a distant plumb-line suspended in a vertical position; for if the intersection of the cross-wires of the telescope will pass along this line, when the plane of the sector is vertical, and when the telescope derives its motion from the screw of the vernier alone, it may be concluded that the line of collimation is parallel to the plane of the sector; but the plane of the sector itself must be previously set right, as it regards the equatorial plate *H*, by the screws that fix it to the inverted cock of the cross, attached to the circular plate *KL*. From a consideration of this instrument, as we have described it, it is obvious, that, provided the telescope, thus having a polar motion and bearing a graduated sector, be made perfectly steady, and placed in the true direction of an hour circle in the heavens, the difference of declination of any two bodies in the celestial regions, that does not exceed the extent of the sector's limb, may be measured to the accuracy of a minute of space, and that whether the two bodies pass the telescope together or successively, provided the elevation of the telescope does not vary in the mean time; and also the difference of right ascension of any two bodies, similarly situated, may be had by noting the difference of sidereal time, (by a regulator,) of their passages over the horary wire; provided the situation of the sector itself does not alter while the telescope is raised or depressed; but much of the accuracy of the results will depend on the steadiness of the parts that are clamped. Were the equatorial sector to be constructed at this time, the reading by a microscopic micrometer would greatly enlarge the powers of this instrument.

"But however well adapted this instrument may be to the purposes for which it was intended," says professor Vince (*Treatise on Pract. Astron.* p. 141, and sec. 7.) "yet it will not conveniently admit of a large telescope; Dr. Maskelyne, therefore, thought of a construction which would admit of one of a larger size, and which has, besides, several other advantages in respect to the adjustments, as will be evident when we come to describe them. The instrument was made by Mr. Sisson, the construction of which we will first describe, and then proceed to its adjustments."

*Equatorial sector by Mr. Jonathan Sisson.*—*AB*, in *fig. 1.* of *Plate XVII.* (of *Astron. Infl.*) is a polar axis, *HI* a circle fixed upon, and at a small distance from it, on the centre of which is an axis, about which the telescope *CD* turns, carrying the indices *a, b*, each having a vernier which subdivides to minutes, and the circle is graduated to shew north polar distances; this, which is called the cross axis, goes through *AB* into a fixed case *E* on the other side, and is moveable by a screw *q* in order to fix it perpendicular to the polar axis: *LM* is an arc of  $22^\circ$  fixed upon *AB*, and concentric with *HI*; *vw* is a vernier whose arm *K* may be screwed to the axis on which the telescope turns, and consequently in that case will turn with it, but if the screws be released, the telescope will turn without it.

*NOPQ* is a brass frame, the two ends of which, *ON*, *PQ*, consist of two pieces, one of which goes over the arc *LM*, and the other under, so that by means of two screws at *y* and *x* to press them together, the frame may be fixed to the arc, in which case the screw *cd*, passing through a nut at *s* on the arm *K*, will move the vernier *vw*; *V* is a brass circle graduated on the edge, and moveable with the screw *cd*, against which is fixed a piece of brass *r* as an index; *W* is a piece of brass fixed on an immoveable piece of wood, on which is another piece not seen to receive the end of the axis *B*, and in which it turns, and this piece is moveable east or west by a screw of adjustment; the end turns in a brass socket *e f*, moveable by a screw *T* in order to alter the inclination of the axis *AB*, and thence adjust it to the latitude; *RS* is an equatorial circle fixed perpendicular to *AB*, having a vernier *mn*; this circle is divided into 24 hours, and each hour into minutes, and the vernier subdivides into seconds.

The adjustments are three; first, to set *AB* parallel to the earth's axis; secondly, to adjust the line of collimation parallel to the circle *HI*; thirdly, to adjust the cross axis perpendicular to the polar axis. The first adjustment consists of two parts, to set the axis at the proper angle, and to place it in the plane of the meridian. Now to adjust the axis to an angle equal to the latitude of the place, the instrument is supposed to be at first fixed as nearly as possible to the true angle, and then the error is to be corrected by adjustment; to do which, turn about the polar axis until the circle *HI* becomes perpendicular to the horizon, and direct the horizontal wire of the telescope to the pole star, or any other whose polar distance is known, when it comes above or below the pole; then turn the axis half round (which is shewn on the equatorial circle); in which case the circle becomes perpendicular to the horizon again; then if the axis be at the proper angle, it is manifest that the telescope is now directed to a point as much below or above the pole as it was above or below before, that is, to the polar distance of the star increased or diminished by the refraction of the star at the first observation; hence, if we turn the telescope till the star be again observed at the same wire, the indices *a, b*, will have moved over twice the refraction, supposing the star to be so near to the pole, that the refraction may be considered the same both above and below; for if the star be first observed above, its apparent place is above the true, and therefore if the telescope and star revolve about the axis till they come below, the telescope is now directed to a point below the true place by the refraction, and as the apparent place is now above the true place by refraction, the telescope is directed to a point distant from the apparent place of the star by twice the refraction; but if it do not move over twice that distance, then half the difference is the error of the angle of the elevation of the axis; move the telescope therefore through twice the distance which the indices *a* or *b* will shew, then turn the telescope, and bring it half way to the star, and by the screw *T* bring the star to the wire, and the axis is adjusted to an angle equal to the latitude of the place; in the same manner we determine whether the axis be in the plane of the meridian, by observing the star in the equator, either in the east or west, and then turning the axis half round, if the axis be rightly adjusted to the meridian, the telescope must be moved  $180^\circ$  in order to bring the star to the same wire; hence if the telescope do describe  $180^\circ$  the axis is right; if not, half the difference is the error; move, therefore, the telescope through  $180^\circ$ , and then by turning it bring it half way to the star, and by the screw at top out of sight bring

## EQUATORIAL.

bring it the other half, and the polar axis is truly adjusted. Secondly, to adjust the line of collimation parallel to the circle  $H I$ . Observe a star in the equator, and note the time of its transit over the middle wire of the telescope by a clock, adjust it to sidereal time, and note also the time shewn by the vernier  $m n$  on the hour circle  $R S$ ; turn the polar axis half way round according to the order of the figures on the hour circle  $R S$ , and the vernier shews a difference of 12 hours; now as the line of collimation is first directed to the equator, it must be perpendicular to the polar axis, and therefore by turning the polar axis about, it must continue to be directed to the equator, whether or not it be parallel to the plane of the circle  $H I$ ; and if this could be done, and the telescope turned about, and the observation repeated without loss of time, the star would appear on the same wire, provided the line of collimation were parallel to the plane of the circle  $H I$ , for then the line of collimation in the second observation being parallel to what it was in the first, it must be directed to the same point in the heavens, the telescope being turned half round; but as this operation will take up some time, the polar axis must be turned a little more than half round in order to bring the star to the same wire, and the vernier would point out the same difference of times as the clock shews in the interval of the observations; but if these differences of times shewn by the clock and the hour circle be not equal, the line of collimation is not parallel to the plane of the circle, and half that inequality of times is the error, which must be corrected by the adjustment for that purpose. Thirdly, to adjust the cross axis perpendicular to the polar axis, or to the line of collimation. By the last adjustment, the line of collimation was made to move in a plane; therefore, if that plane be adjusted to the polar axis, the line of collimation will describe a secondary to the equator. On this supposition, if we take a star of any declination, and note the time of its transit over the middle wire by the clock, and also the hour on the hour circle; then turn the polar axis half round, and observe again as in the last position, and the differences of the times of the two observations shewn by the clock, and on the hour circle diminished by 12, must be equal; but if the line of collimation do not describe a secondary, the differences will not be equal. To correct, therefore, this error, let  $E Q$ , *fig. 2. Plate XVII.* be the equator,  $E P Q$  a great circle passing through the pole  $P$ ,  $E F Q$  the great circle described by the line of collimation, and let the telescope be directed to a star  $z b$ , and let  $d b y$  be a portion of its parallel, take  $a d = a b$ , and draw the secondaries  $P d m$ ,  $P b c$ . Now it is manifest, that if we turn the polar axis half round, the plane  $E F Q$  will then lie as much on the contrary side of  $E P Q$ ; and, therefore, when the telescope is directed to the star's parallel, it will cut it at  $d$ , and half  $m C$ , or  $E c$ , is the error of right ascension. Note the time on the hour circle, and continue to turn (in the present instance) the polar axis until the star, now at  $x$ , on account of its motion, be again brought to the middle wire, and note again the time on the hour circle, and we have the difference  $m r$  shewn by the hour circle, from which subtract the time  $c r$ , shewn by the clock between the observations, and we have  $m C$ , the half of which is  $E c$ . Now the star being on the middle wire, move the polar axis so as to cause the hour circle to move through an arc  $r s$  equal to  $E c$ , and by the screw  $g$ , *fig. 1.* alter the position of the cross axis, and consequently of the plane  $E F Q$  till the star appears again on the same wire, moving, if necessary, the telescope on the circle  $H I$  to bring the star into the field; and then as  $y x = a b$ , the line of collimation would have been corrected so as to make it pass through  $P$ ,

and the adjustment would have been truly made, provided the star had not moved in the time of this last operation. Correct again, therefore, and you will get the line of collimation to describe a secondary to the equator, when the telescope is moved on the circle  $H I$ . Thus the instrument is adjusted for use.

*To find any object in the heavens, whose right ascension and declination are known.*—Find its distance, at the time required, from the meridian in the usual way, and reduce it to sidereal time, and turn about the polar axis, that way the object lies from the meridian, until the hour circle points out that distance of the telescope from it; then turn the telescope till the indices  $a, b$ , shew the polar distance, and the object will be in the field of view. By this means we direct the telescope to a comet, or any other body whose place is known, which is invisible to the naked eye.

*To find the true place of a body, and trace out its path in the heavens.*—Screw the index  $K$  to the cross axis of the telescope; bring the body upon the wire parallel to the equator, and take the time of its transit over the middle wire perpendicular to it, and note the degrees on the arc  $L M$ , pointed out by the vernier  $v w$ ; then if there be any known fixed star near its parallel, move the telescope on the circle  $H I$  (the polar axis remaining fixed) to the star's parallel, wait till the star enters the field of view, and make it run along the same wire as the body did, and take the time of its transit at the middle wire, and the difference of these times will give the difference of their right ascensions, and the difference of the arcs on  $L M$ , pointed out by the vernier  $v w$  at the times of the transits, gives the difference of their declinations; hence the right ascension and declination of the body is known. Continue these observations as long as the body is visible, and you will get its path in the heavens. The utility and convenience of this method is, that we can at any time determine the place of a body without waiting for its coming to the meridian; where, besides the inconvenience of waiting, an observation might be hindered by the badness of the weather, or the body might come to the meridian in the day-time, when it could not be seen.

An instrument, somewhat similar in construction, but with considerable improvements, was begun by Mr. Bird in the last year of his life, or the year preceding, for the observatory at Oxford, and was finished by Mr. Troughton (the senior) about the year 1773, by order of Mr. Bird's executors. We regret that we have not had the means, in due time, of obtaining a perspective drawing of this instrument, that we might have gratified our readers with a description of it.

*EQUATORIAL Stand* of a telescope is a contrivance for making a common telescope follow a celestial body in its apparent path along, or parallel to, the equator; and answers the purpose of a polar axis of motion, while it adds but little to the expence of a simple stand for horizontal and vertical motions only. The thing required to be done to a common stand, was to give the horizontal motion an equatorial direction, and then the vertical motion, of itself, becomes a motion in declination, or in an horary circle, as well out of, as in the meridian. Various methods have been devised of effecting this purpose in the simplest way; but the contrivance invented by Mr. Smeaton, usually called *Smeaton's Block*, and which has all the advantages of cheapness, stability and simplicity, has been preferred to all others, and in our opinion merits a place in our collection of astronomical instruments.

*Fig. 5. of Plate XIII. of Astron. Infl.* is a representation of an equatorial stand of Smeaton's construction, in which  
the

the three legs are of mahogany, well braced together, and shortened at the lower extremities for the purpose of bringing them within the plate. The part *ab*, at the top of the legs, in the shape of a blunt wedge, is of mahogany, and is fast to the legs; the other similar part *cd*, above it, is also mahogany, and sloped exactly like the part *ab*; the two parts taken together are called the *block*, the lower half of which is fixed, and the upper moveable on a strong cylindrical piece of brass fixed to the piece *cd*, at right angles to the line of section, or plane of contact, and passing through the piece *ab* so as to be fixed, when necessary, by a finger screw below the block, and within the junction of the three legs. The plane of contact of the two halves of the block is so sloped as to make an angle exactly equal to one half of the co-latitude of the place of observation, with a horizontal line, in which the under-face of the block is supposed to be by its position; but as the upper half of the block is exactly similar to the under one, its face, when in the present equatorial position, makes an angle with the horizon equal to the whole co-latitude of the place; *i. e.* when in the meridian, is coincident with the plane of the equator. When the part *cd* is turned half round, so that the point *d* may coincide with the point *a*, and the point *c* with the point *b*, the slopes of the two halves of the block are then reversed, and the face of *cd* becomes horizontal: hence it appears that a motion of the half block *cd* round its axis of motion, will carry any telescope *g*, or other body, placed on it parallel to its face, in the direction of the equator, provided it be placed in the meridian of the place when it has the greatest elevation. Accordingly an axis of motion of a small graduated equatorial circle *e* is attached perpendicularly to the face of the half block *cd*, round which the said circle is moveable; and over this circle is mounted a graduated semicircle of declination *f*, or of altitudes, when the block is in its horizontal position, to which the telescope is made fast. The circle *e* is divided into half degrees, or two minutes of time, and is subdivided by a vernier into  $\frac{1}{10}$ th of this quantity, that is, into minutes of space, and four seconds of time; the declination-semicircle is also subdivided into minutes of space by a vernier; and by enlarging the radii the subdivisions might be rendered still more minute; but the use of these graduations is merely to find a star or planet, by its right ascension and declination, to which purpose the instrument is quite competent. Mr. Troughton informs us, that he has made this stand an universal one sometimes, by dividing the block diagonally by an angle of  $45^\circ$ , in which case it would take any degree of elevation from a horizontal to a vertical position, and one of the half blocks, being graduated into  $360^\circ$ , was read by a vernier fixed to the other, so as to ascertain any given quantity of elevation; but as the construction of the instrument does not admit of great accuracy in its adjustments and motions, he considered such addition rather as curious than really useful in astronomy. Still, however, when the telescope is fitted up with the best micrometer for measuring the difference of right ascensions and declinations, and when the stand is made very steady, the instrument may be very serviceable in an observatory, and is often made a part of its furniture.

The sliding tubes *h* are sometimes superadded to brace the eye-end of the telescope, and are found to answer a good purpose, when well made, and fitted to any pair of the legs that may happen to be turned towards this end of the telescope. Both the equatorial circle *e* and semicircle *f* have the usual apparatus for quick or slow motion; and when the block is in the horizontal position, the telescope may be fixed, by the finger screw under the block, to be conveniently used for viewing terrestrial objects; in which posi-

tion the instrument makes no contemptible theodolite, as well as equal-altitude instrument, when a level is added.

**EQUEA**, in *Geography*, a town of Africa, on the Gold coast.

**EQUERY**, or **ECURY**, a grand stable or lodge for horses, furnished with all the conveniences thereof; as stalls, manger, rack, &c.

The word is formed from the French, *escurie*, which signifies the same thing. Some again derive *escurie* from the Latin, *scuria*, which not only denotes a place for beasts to be put up in, but also a grange or barn. But a more probable derivation is from *equile*, a stable for horses, of *equus*, horse.

Some hold that the word stable, in propriety, relates only to bullocks, cows, sheep, hogs, &c. and equery, to horses, mules, &c.

A simple equery is that provided for one row of horses; a double equery that provided for two, with a passage in the middle, or two passages; the horses being placed head to head, as in the little equery at Versailles.

Under equery are sometimes also comprehended the lodgings and apartments of the equeries, grooms, pages, &c.

**EQUERY**, *escuyer*, is also an officer who has the care and management of the horses of a king or prince.

**EQUERIES**, or **EQUERRIES**, popularly called *querries*, are particularly used amongst us for offices of the king's stables, under the master of the horse, five in number, who, when his majesty goes abroad, ride in the leading-coach, are in waiting, one at a time, monthly, and have a table with the gentlemen-ushers during the time, and a salary of 300*l.* a-year each: that of the first equerry and clerk-martial being 500*l.*

They used to ride on horseback by the coach side when the king travelled: but that being more expensive to them than necessary to the sovereign, it has been discontinued.

**EQUERIES of the crown stable**, have that appellation, as being employed in managing and breaking the saddle-horses, and preparing them for the king's riding.

The equerry of the crown stable has an annual salary of 200*l.* and is, or always should be, in close waiting at court; and when his majesty rides holds the stirrup, while the master of the horse, or one of the equeries in his absence, assists in mounting him; and when his majesty rides, they usually attend him. To the establishment of the queen's household belong two equeries with a salary of 220*l.* each. There are also two belonging to the prince of Wales's household. Officers under the same denomination form a part of the established households of the royal dukes, &c.

**EQUES AURATUS**, is used to signify a knight bachelor, called *auratus*, *q. d. gilt*, because anciently none but knights might gilt or beautify their armour, or other habiliments of war, with gold.

In law this term is not used, but instead of it *miles*, and sometimes *chevalier*.

**EQUESTRIA**, among the Romans, a place in the theatre where the equites or knights sat.

**EQUESTRIS**, **EQUESTRIAN**, formed of the Latin, *equus*, knight, horseman, of *equus*, horse, a term chiefly used in the phrase equestrian statue, which signifies a statue representing a person mounted on horseback.

The Fortuna equestris, in ancient Rome, was a statue of the goddess on horseback. We sometimes also say, *equestrian column*, which see.

**EQUESTRIAN cohort**, in *Antiquity*. See **COHORS equitata**.

**EQUESTRIAN games**, *ludi equestres*, among the Romans, horse-races, of which there were five kinds, the prodromus,

or plain horse-race, the chariot race, the decurfory race, about funeral piles, the ludi fevirales, and the ludi neptunales.

EQUESTRIAN order, among the Romans, signified the order of the knights or equites.

EQUI, in *Ancient Geography*, a small town of Africa Propria, near a lake in the vicinity of Utica. According to Diodorus Siculus it was taken by Agathocles.

EQUIANGULAR, in *Geometry*, is applied to figures whose angles are all equal; such are the square, and all regular figures.

All equilateral triangles are also equiangular.

An equilateral figure inscribed in a circle is always equiangular; but an equiangular figure inscribed in a circle is not always equilateral, except when it has an odd number of sides. If the number of the sides be even, then they may be either all equal, or else half of them will always be equal to each other, and the other half to each other; the equals being placed alternately. See Hutton's *Math. Misc.* p. 272.

EQUIANGULAR is also applied to any two figures of the same kind, when each angle of the one is equal to a corresponding angle in the other, whether each figure, separately considered, be an equiangular figure or not, that is, having all its angles equal to each other. Thus, two triangles are equiangular to each other, if, *e. g.* one angle in each be of  $30^\circ$ , a second angle in each of  $50^\circ$ , and the third angle of each equal to  $100^\circ$ .

Equiangular triangles have not their like sides necessarily equal, but proportional to each other; and such triangles are always similar to each other.

EQUICRURAL TRIANGLE, is what we more usually call an isosceles triangle.

EQUICULUS, EQUULEUS, or *Equus minor*, in *Astronomy*, a constellation of the northern hemisphere. See EQUULEUS.

EQUIDIFFERENT, in *Arithmetic*. If in a series of three quantities there be the same difference between the first and second as between the second and third, they are said to be continually equidifferent; but, if in a series of four quantities, there be the same difference between the first and second as between the third and fourth, they are said to be discretely equidifferent.

Thus, 3, 6, 7, and 10, are discretely equidifferent, and 3, 6, and 9, continually equidifferent.

EQUIDISTANT, in *Geometry*, a term of relation between two things which are every where at an equal or the same distance from each other. Thus, parallel lines are said to be equidistant, as they neither approach nor recede.

EQUILATERAL, of *æquus*, equal, and *latus*, side, is applied to any figure whose sides are all equal. Thus, an equilateral triangle is that whose sides are of equal length. In an equilateral triangle all the angles are likewise equal. See EQUIANGULAR.

All regular polygons and regular bodies are equilateral. See POLYGON, REGULAR, &c.

EQUILATERAL Hyperbola, is that in which the conjugate axes, and every pair of conjugate diameters, are equal to each other. The asymptotes are also at right angles to each other, and each of them forms a right angle with the axis. Such an hyperbola is also equal to its opposite hyperbola, and likewise to its conjugate hyperbola, so that all the four conjugate hyperbolas are mutually equal to each other.

Hence, as the parameter is a third proportional to the

conjugate axes, they are all mutually equal; consequently,

if in the equation for the hyperbola  $y^2 = \frac{p}{t} \times tx + x^2$ , or =

$\frac{c^2}{t^2} \times tx + x^2$ , in which  $t$  is the transverse axis,  $c$  the conjugate,  $p$  the parameter,  $x$  the absciss, and  $y$  the ordinate,  $t$ ,  $c$ , and  $p$  being made equal, the equation for the equilateral hyperbola becomes  $y^2 = tx + x^2$ ; differing from that of the circle merely in the sign of the term  $x^2$ , which in the circle is —. See HYPERBOLA.

EQUILIBRIUM, or EQUIPOISE, in *Mechanics*, means an equality of forces acting in opposite directions, so that they mutually balance each other. Thus, the scales of a balance are said to be in equilibrio, when neither of them preponderates, in consequence of which the beam of the balance remains perfectly horizontal. But, it must not be imagined, that the equality of weights alone determines the equilibrium of mechanisms in general; for that is only the case when the velocities and directions are equal, as in the above-mentioned case of the balance, where the two arms of the beam being equal, the weights in the scales have equal velocities, supposing that the balance is made to vibrate, and move in vertical directions. Therefore, it has been said above, that the equilibrium takes place, when the forces, which act in opposite directions, are equal; for the forces are estimated from the weight of the bodies, their velocities, and directions conjointly. Thus, in the common mechanical powers, the equilibrium takes place, when the power is to the weight as the velocity of the weight is to the velocity of the power. The equilibrium of solids forms a considerable part of the science of statics, and the equilibrium of fluids forms a considerable part of hydrostatics.

EQUILIBRIUM is also used figuratively on other occasions. A painter must take care to observe the equilibrium of his figures, *i. e.* dispose them well on their centre of gravity, that they may not seem ill-supported, or ready to tumble. Thus, *e. gr.* if one arm be moved forward, the other must be proportionably backward to poise the figure.

In a picture there should always be an equilibrium between one part and another; that is, the objects are to be distributed so as to balance and contrast each other; and not too many, *e. gr.* be crowded on one side, and the other be left bare.

EQUIMULTIPLE, in *Arithmetic* and *Geometry*, is applied to simple magnitudes when multiplied equally, *i. e.* by equal quantities or multipliers.

Thus, taking A as many times as B, or multiplying them equally, there will still remain the same ratio between the magnitudes thus multiplied, as between the primitive magnitudes before multiplication.

Now those magnitudes, thus equally multiplied, are called equimultiples of the original ones A and B; whence we say, that equimultiples have the same ratio as the simple quantities. In arithmetic, we generally use the term equimultiples for numbers which contain equally or an equal number of times their submultiples.

Thus 12 and 6 are equimultiples of their submultiples 4 and 2, inasmuch as each of them contains its submultiple three times.

EQUINA SELLA. See SELLA.

EQUINOCTIAL, in *Astronomy*, a great circle of the sphere, under which the equator moves in its diurnal motion.

The equinoctial is conceived by supposing a semidiameter of the sphere produced through a point of the equator, and there, by the rotation of the sphere about its axis, describing a circle on the immoveable surface of the primum mobile.

The

The poles of this circle are the poles of the world. The sphere is divided by it into two equal parts, the northern and southern. It intersects the horizon of any place in the east and west points; and at the meridian its elevation above the horizon is equal to the co-latitude of the place.

Whenever the sun, in his progress through the ecliptic, comes to this circle, it makes equal days and nights all around the globe; as he then rises due east and sets due west, which he never does at any other time of the year. And hence the denomination from *æquus* and *nox*, night, *quia æquat diem nocti*. All the stars that are under this circle, or that have no declination, do also rise due east and set due west.

The equinoctial, then, is the circle which the sun describes, or appears to describe, at the time of the equinoxes: that is, when the length of the day is every where equal to that of night, which happens twice a year. (See EQUINOX.) From this circle is the declination in the heavens or latitude of places on the earth counted in degrees of the meridian. Upon this circle is reckoned the longitude,  $180^{\circ}$  west and  $180^{\circ}$  east, in all  $360^{\circ}$ . Hence,  $1^{\circ}$  of longitude answers to  $4'$  of time;  $15'$  to  $1'$  of time; and  $1'$  to  $4$  seconds of time, &c.

The shadows of those who live under this circle are cast to the southward of them for one-half of the year, and to the northward of them during the other half; and twice in a year, *viz.* at the equinoxes, the sun at noon casts no shadow, being in their zenith.

EQUINOCTIAL *colour*, is that passing through the equinoctial points. See *COLURE*.

EQUINOCTIAL *dial*, is that whose plane lies parallel to the equinoctial. See *DIAL*.

EQUINOCTIAL *hours, line, orient*. See the substantives.

EQUINOCTIAL *points*, are the two points wherein the equator and ecliptic intersect each other: the one, being in the first point of Aries, is called the vernal point, or equinox; and the other, in the first point of Libra, the autumnal point, or equinox.

The equinoctial points, and, indeed, all the other points of the ecliptic, are found, by observation, to be continually moving backwards, or in antecedentia, *i. e.* towards the west. This retrograde motion is called the *Precession of the equinoxes*; which see.

EQUINOX, in *Astronomy*, the time when the sun enters one of the equinoctial points.

The equinoxes happen when the sun is in the equinoctial circle, of consequence the days are equal to the nights throughout the world, which is the case twice a year, *viz.* about the 21st of March, and the 22d of September, the first of which is the vernal, and the second the autumnal equinox.

As the sun's motion is unequal, that is, sometimes swifter and sometimes slower (from the causes already explained under the article *EQUATION*), it comes to pass, that there are about eight days more from the vernal to the autumnal equinox than from the autumnal to the vernal, the sun spending so much more time in travelling through the northern than the southern signs.

According to the observations of M. Cassini, the sun is  $186^{\text{d}} 14^{\text{h}} 53'$  in the northern signs, and only  $178^{\text{d}} 14^{\text{h}} 56'$  in the southern. The difference of which is  $7^{\text{d}} 23^{\text{h}} 57'$ .

The sun, continually advancing forwards in the ecliptic and gaining a degree every day, makes no stay in the equinoctial points, but the moment he arrives in them he also leaves them.

Of course, therefore, though the day the sun enters the

equinoctial point is called the equinox,  $\ast$  being reputed equal to the night; yet it is not precisely so, unless the sun enter the equator at mid-day: for if the sun rising, should enter the vernal equinox at setting, he will have departed from it, and have got northwards about  $12'$ ; consequently, that day will be somewhat longer than 12 hours, and the night proportionably shorter.

The time of the equinoxes, *i. e.* the moment in which the sun enters the equator, is found by observation, the latitude of the place of the observation being given.

Thus, in the equinoctial day, or near it, take the just meridian altitude of the sun; if this be equal to the altitude of the equator, or the complement of the latitude, the sun is that very moment in the equator: if it be not equal, the difference is the sun's declination. The next day observe the meridian altitude as before, and find his declination; if the declination be of different kinds, *viz.* the one north and the other south, the equinox has happened in the interval of time between them; otherwise, the sun has not entered the equinoctial, or had passed it at first. From these observations a trigonometrical calculus gives the time of the equinox.

Thus, let DG (*Plate XII. Astronomy, fig. 110.*) represent the equator, AC the ecliptic, E the equinoctial point; the points A, B, C, the places of the sun at the times of observation; the arcs AD, BE, CG, the corresponding declinations; in the right-angled spherical triangles CEG, BEF, the obliquity of the ecliptic, and the declinations are known; whence may easily be found EC, EB; then BC, the sum or difference of EC, EB is the ecliptic arc described in 24 hours: then say as BC : BE :: 24 hours for BC : time for BE; and this time shews the distance of the equinox from the time of the middle observation.

EQUINUS BARBATUS, a kind of comet. See *HIPPEUS*.

EQUINUS *ellipticus* and *quadrangularis*. See *HIPPEUS*.

EQUINUS *venter*. See *VENTER equi*.

EQUIP, *To*, in *Naval Language*, a term borrowed from the French marine, and frequently applied to the business of fitting a ship for sea, or arming her for war. See *FITTING-OUT*.

EQUIPAGE, in *Navigation*. See *CREW* and *FITTING-OUT*.

EQUIPAGE, *Camp*. Under this term we confine ourselves entirely to what relates to the tents generally in use; remarking, that such as suit admirably for a cold climate, would be found totally unserviceable in higher latitudes, where the air, confined in a small space, under a vertical sun, while probably not a leaf is in motion, could not fail to be unfit for respiration. Therefore, we shall give the regulation sizes of tents, both according to the home service, and to what is found necessary for troops employed in the East Indies.

*Home Service, Laboratory Tent*, with mallets, poles, pins, &c. should weigh 3 cwt. 24 lb.; and ought to be sustained on poles of  $14\frac{1}{2}$  feet each in length; the ridge pole should be 18 feet. Some of these are made with half-walls; that is, their flies, or canopies, do not come within three feet of the ground, but are there fastened to a half-wall, or curtain, which being laced or hooked to the interior of the fly, hangs perpendicularly to the ground, to which it is secured by wooden pins, or pegs.

*India Service, Laboratory Tent*.—This class of tents is nearly similar, but they have commonly extra flies, standing at about a yard distant from the inner shell, which are sometimes

well soaked in oil, or slightly with tar, at least sufficiently to throw off rain. This occasions them to be extremely ponderous; the poles being some feet longer, and the spread of canvas considerably greater; the average weight of a laboratory tent may here be taken at nearly half a ton. Such a weight could only be conveyed on an elephant, or on a cart, (the latter being far too dilatory for most situations,) were it not that the fly, the shell, and the walls, are all made to separate. By this means two camels may conveniently bear one of these tents.

*Home Service, Bell Tent*, should, according to the new construction, have a pole of 9 feet long, and form a circular spread of 14 feet in diameter, so as to give shelter to twelve men. Since it has been found necessary to reduce the quantity of baggage attached to our armies, little or no use is made of any tents that are inadequate to the shelter of a certain number of persons; consequently those bell tents, which were called "Bells of Arms," have in a manner ceased to be known in our arsenals, they being totally incompetent to any essential service. The modern bell tent is, therefore, to be considered as a medium between the bells of arms, and the private tents formerly in use; they are extremely portable, and, in proportion to their weight, which ought not to exceed 45 lb. are far more serviceable; as they cover twelve men better than the common infantry tents, that weighed 27 lb., did five. The facility with which a tent, having only a pole, is raised, or struck, the great safety it insures from presenting no flat side to the wind, and the paucity of pins, &c. requisite for its use, give it a very considerable claim to preference.

*Indian Service, Bell Tents*, are made of very stout canvas, supported on poles of about 7 feet in length, and overlapping in their front, for the purpose of keeping the arms they contain perfectly dry. The musquets, &c. are filed round the pole of a bell tent by means of two sticks, about 18 inches in length, passing at right angles to each other, and to the pole also, through two holes made in the latter. These, which may be drawn at pleasure, form a cross, in the four divisions of which the arms of the company are filed. Average weight, when dry, 1 cwt.; when wet, 1 cwt. 1 qr. 14 lb.

*Home Service, Common Infantry (or Private) Tents*, which are now less used than formerly, require two standard poles, each 6 feet in length, and a ridge pole of 7 feet. They should weigh *in toto* 27 lb., and be capable of covering five men. It is obvious, that a tent of this description must be less safe, and less comfortable to its inhabitants, than the bell tent now substituted.

*Indian Service, Private Tents*, stand upon two poles, each 9 feet long, and have a ridge pole of 8 feet. These tents are made of very strong canvas, and are sometimes lined separately; whereby they are rendered tolerably cool. They should be capable of sheltering twelve men commodiously; but in hot weather not more than eight ought to be allotted to one tent. Considerable relief is afforded by the walls of these tents; which are generally about 30 inches high. The average weight of one, complete, may be about 2 cwt. 1 qr. when dry; but when wet, it will perhaps exceed 4 cwt.

*Home Service, Officer's Marquee*, should have two standard poles, each 8 feet high, and a ridge pole of 7 feet: the total weight about 130 lb. This kind of tent has walls about 4 feet in height, and is generally furnished with a separate lining throughout.

*Indian Service, Marquees*, are upon a very different construction. The proportions are as follows; *viz.*

	Length.	Breadth.	Ridge Poles.	Standard Poles.
Captain's marquee on two poles lined throughout with gingham, and having walls of 5 ft. 6 in.	23 feet.	15 feet.	10 feet.	12 feet.
Subaltern's tent on 1 pole	14 feet.	14 feet.	—	11 feet.

These proportions may seem very great, but they are found to be actually necessary in that climate. The total weight of a captain's marquee may be estimated, when dry, at 4 cwt.; when wet, at 6½ cwt. A subaltern's marquee, when dry, 3½ cwt.; and when wet, 5 cwt.

With respect to the larger classes of tents, such as are used by our colonels and general officers, they approach somewhat towards the construction of what, in the Indian service, are called field officers' sleeping tents, which generally have from 12 to 14 feet between two poles of 14 feet in height. They are chiefly composed of strong shells made of Russia-duck, with flies of canvas, and are ordinarily lined with perpet. The weight of such a tent may be computed at 5 cwt. when dry; and when wet at 7½ cwt. State tents may measure about 18 feet in the ridge, and have standards of full 16 feet in height. Their poles are generally made in two pieces, joining in their centres by means of a cylinder of iron; on the same principle as the sliding ferrils in ladies' parasols.

We have thus given some insight into the proportions between the tents appropriated to the several classes, so far as they could tend to instruct the reader; who will, of course, understand, that in proportion as the standards of a tent are lengthened, so will the several slopes of the fly be lengthened in a suitable ratio. The ordinary computation is, that the direct depth of the slope ought to be two-thirds the length of the poles where a full wall is to be attached; four-fifths where a half-wall is to be furnished; and that the pole should be one-quarter, or even a third, less in length than the direct slope of the fly is deep, if no walls whatever are to be added. The climate will indicate the necessity for more or less steepness in the slope; for if little rain falls, less declivity will answer; whereas, if, as in India, the rains are abundant and heavy, such a slope must be given as may insure that the interior should remain dry.

It is of the utmost importance, that all camp equipage should be made not only conformably to a particular pattern, thereby to preserve uniformity of appearance; but, as nearly as practicable, of the same kind of materials, and of a given weight; so that a very correct estimate may be formed both of the bulk and gravity of the whole, when about to be conveyed either by land or by water. Besides, it is expedient, that the camp-colourmen, batmen, &c. should have a perfect understanding of this branch of military economy, and have the whole of the tents handed to them, when about to be laden, or conveyed, packed in a regular manner; so as to occupy as little space as possible; otherwise they never can flow to advantage, so as to be safe, and to afford as much space as can be spared for other articles.

**EQUIPAGE**, in the *Military Art*, denotes all sorts of utensils, artillery, &c. necessary for commencing and prosecuting with ease and success any military operations.

**EQUIPOLLENCE**, in *Logic*, is when there is an equivalence between any two or more terms or propositions; *i. e.* when they signify one and the same thing, though they express it differently. Such propositions, &c. are said to be equipollent.

**EQUIPPE'**, in *Heraldry*, expresses a cavalier equipped, *i. e.* armed at all points.

**EQUIRIA**, in *Antiquity*, a festival instituted by Romulus, and celebrated on the 27th of February, in honour of Mars, at which there were horse-races.

**EQUISELIS**, in *Natural History*, the name of a large fly, of the size of a hornet, but having only two wings and no sting: it otherwise much resembles the common hornet in shape. This fly is found only in Macedonia. We have also in England flies which nearly resemble the hornet, wasp, and bee, but in their wanting stings and having only two wings.

**EQUISELIS**, in *Ichthyology*, a name used by some authors for a sea-fish, caught on the Spanish shores, and supposed by many to be the same with the *Dorado*, or *Coryphæna*, with the forked tail of Artedi. See *CORYPHÆNA*.

**EQUISETUM**, in *Botany*, from *equus*, a horse, and *feta*, a strong hair or brittle. Horsetail. Plin. Hist. Nat. lib. 26. cap. 13. Linn. Gen. 559. Schreb. 753. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 1102. Hedwig. Theor. 33. t. 1, 2. Juss. 17. Class and order, *Cryptogamia Filices*. Linn. *Cryptogamia Miscellaneæ*. Schreb. Nat. Ord. *Filices spicate*.

Gen. Ch. *Fruifications* in an ovate-oblong terminal catkin, composed of whorled, stalked scales. Each scale peltate, somewhat orbicular, but with many sides, bearing on its under side from four to seven tubular, angular, obtuse sheaths, parallel to and surrounding the stalk of two valves, bursting internally, containing numerous florets. *Stam.* Filaments four, coiled up round the germen, in a spiral manner, while moist, divaricated when dry; anthers terminal, simple, spatulate. *Pist.* Germen globose, wrapped up in the stamens; style none; stigma obsolete, acute. *Seeds* globose, deciduous, accompanied by the stamens.

Ess. Ch. Catkin with peltate scales, fructifying on their inside. Partial involucrems tubular, of two valves. Seeds numerous, naked, surrounded by four spiral stamens.

Many different opinions have existed concerning the fructification of this genus, but Hedwig's, as above given, seems to us the most satisfactory. In the artificial classification we retain it among the ferns, to which it is closely allied in natural affinity, though of itself a most natural and distinct genus; nor do we think Schreber's order, entitled *Miscellaneæ*, lessens in any degree the difficulties respecting this tribe.

Seven species of *Equisetum* are found in Britain, and two or three foreign ones are imperfectly known besides.

*E. sylvaticum*, Engl. Bot. t. 1874, known by its compound drooping branches, is one of the prettiest. It occurs chiefly in mountainous countries, in moist, shady spots.

*E. hyemale*, Engl. Bot. t. 915, called Shave-grass or Dutch rush, is remarkable for the callous roughness of the ribs of its naked stem, which renders it useful in polishing wood, ivory, and even brass. Being rare in England, it has for these purposes been imported from Holland. Professor Davy has detected a large proportion of stinty earth in the cuticle, to which its hardness and asperity are owing.

*E. variegatum*, Engl. Bot. t. 1987, found on the sandy-sea-coast of Scotland, by Mr. G. Don, and a native also of Sweden, Denmark, Switzerland, &c. is a smaller species, nearly related to the last, and having a similar roughness.

*Equiserum*, in *Natural History*, is the name by which some writers have denominated certain fossil plants, (*phytolithii*), which are found bearing some faint resemblance to the recent plant called horse-tail. Mr. William Mar-

tin, after describing an organic remain of this kind in his "*Petrificata Derbienia*," says, "there are other plants with stellate leaves, to which it might with as much propriety be referred: *hippuris*, *asperiala*, and *galium*, for instance," and he continues, "we may here observe, that little has yet been done with respect to discriminating the original genera of fossil plants: those parts indeed, on which such discrimination *must* be founded, are rarely, if ever, visible in the petrified state. The characteristic distinctions of the species are frequently attainable, if studiously sought after, by a diligent and careful comparison of various specimens; and the habit or general appearance of the fossil often leads to the knowledge of the natural class and order of the recent plant: but its genus, for the most part, remains undetermined or doubtful." The great importance of the organic remains or *reliquia* in tracing and identifying the strata, according to the new discoveries of Mr. Smith and his pupils, will, it is hoped, ere long, induce naturalists seriously to turn their attention to this neglected branch of science.

**EQUISONANCE**, in *Music*, a name by which the ancients distinguished octaves from other concords. Octaves being the only *paraphoni*, or concords, when doubled above or below. This is a distinction which would be as useful in modern music as in the ancient. All other concords, doubled, become discords.

**EQUITANTIA, FOLIA**, in *Botany*, is applied to leaves so folded at the base, as to embrace each other in two ranks. See *LEAF*.

**EQUITATA COHORIS**, in *Antiquity*. See *COHORIS Equitata*.

**EQUITY, ÆQUITAS**, denotes justice or right, mitigated and tempered by the consideration of particular circumstances; or a correction and abatement of the severity of some law; or a temperament, which, without being unjust, abates the rigour of some just law.

Equity, as Grotius defines it, is the correction of that, wherein the law (by reason of its universality) is deficient. For since in law all cases cannot be foreseen or expressed, it is necessary, that when the general decrees of the law come to be applied to particular cases, there should be somewhere a power vested of defining those circumstances, which (had they been foreseen) the legislator himself would have expressed. And these are the cases which, according to Grotius, "*lex non exactè definit, sed arbitrio boni viri permittit.*"

This is what the Greeks call *επιεικειη*. The utmost severity of a good law is frequently contrary to justice; it should always have equity for its rule and guide. "*Summum jus, sæpe summa injuria.*"

The foundation of equity is not that there is any mistake in the law, but that the law was laid down universally, because all circumstances could not be considered or taken in under one law.

For an instance, suppose it an express law, that the city being now beset with an enemy, the gates be all shut; and suppose it fall out that the enemy is then in pursuit after some of the citizens by whom it is defended, so that it would be highly prejudicial thereto not to open for them the gates; equity here decrees the gates to be opened, contrary to the express words of the law.

As equity depends, essentially, upon the particular circumstances of each individual case, there can be no established rules and fixed precepts of equity laid down, without destroying its very essence, and reducing it to a positive law. And, on the other hand, the liberty of considering all cases in an equitable light, must not be indulged too

## EQUITY.

far; lest we thereby destroy all law, and leave the decision of every question entirely in the breast of the judge. And law, without equity, though hard and disagreeable, is much more desirable for the public good, than equity without law; which would make every judge a legislator, and introduce infinite confusion, as there would then be almost as many different rules of action laid down in our courts, as there are differences of capacity and sentiment in the human mind.

Equity is of two kinds, and those of contrary effects; the one abridges, and takes from the letter of the law; and the other enlarges, and adds to it.

The first is defined the correction of a law, made generally in that part wherein it fails; as suppose a statute made, "that whosoever does such a thing shall be a felon, or suffer death:" yet if a mad-man, or an infant, who hath no discretion, do the same, he shall neither be a felon nor suffer death.

The other is defined an extension of the words of the law to cases which are not expressed, which yet come under the same reason: so that when one thing is enacted, all other things which are of the like degree are so too.

Thus, the statute which ordains, that in action of debt against executors, he who appears by distress shall answer, extends by equity to administrators; and such of them as shall appear first by distress, shall answer by the equity of the said act, "quia sunt in æquali genere."

EQUITY is also used for the virtue of justice. See JUSTICE.

EQUITY, in our *Laws*, &c. is also frequently used for the COURT of *Chancery*, (which see,) where controversies are supposed to be determined according to the exact rules of equity and conscience, by mitigating the rigour of the common law.

"Æquitas sequitur legem," is an old maxim in law; but, from the great increase of suits in chancery, some have thought fit to give it this construction, that in all cases after a man has been at law, he must go to equity.

Judge Blackstone has given a brief, but comprehensive view of the nature of equity, as it is now understood and practised in our several courts of judicature. Equity, he says, in its true and genuine meaning, is the soul and spirit of all law; *positive* law is construed, and *rational* law is made by it. In this, equity is synonymous to justice: in that, to the true sense and sound interpretation of the rule. But the very terms of a court of *equity*, and a court of *law*, as contrasted to each other, are apt to confound and mislead us; as if the one judged without equity, and the other was not bound by any law. Whereas every definition or illustration to be met with, which now draws a line between the two jurisdictions, by setting law and equity in opposition to each other, will be found either totally erroneous, or erroneous to a certain degree. Thus, in the *first* place, it is said, that it is the business of a court of equity in England to abate the rigour of the common law; but no such power is contended for. The learned judge specifies various cases of positive law, in which the court of equity can give no relief, and in which these, as well as the courts of law, must say with Ulpian, "hoc quidem perquam durum est, sed ita lex scripta est." Again it is said, that a court of equity determines according to the spirit of the rule, and not according to the strictness of the letter: but so also does a court of law. Both, for instance, are equally bound, and equally profess, to interpret statutes according to the true intent of the legislature. In general laws, all cases cannot be foreseen; or, if foreseen, cannot be expressed: some occur that will fall within the mean-

ing, though not within the words of the legislator; and others, which may fall within the letter, may be contrary to his meaning, though not expressly excepted. These cases, thus out of the letter, are often said to be within the equity of an act of parliament; and so cases within the letter are frequently out of the equity. Here by equity we mean nothing but the sound interpretation of the law; though the words of the law itself may be too general, too special, or otherwise inaccurate or defective. These are the cases to which Grotius refers in the passage cited above. But there is not a single rule of interpreting laws, whether equitably or strictly, that is not equally used by the judges in the courts both of law and equity; the construction must in both be the same, or, if they differ, it is only as one court of law may also happen to differ from another, each endeavours to fix and adopt the true sense of the law in question: neither can enlarge, diminish, or alter that sense in a single tittle.

It has been further said, that *fraud*, *accident*, and *trust*, are the proper and peculiar objects of a court of equity. But every kind of *fraud* is equally cognizable, and equally adverted to, in a court of law. Many *accidents* are also supplied in a court of law. And, although a technical *trust*, created by the limitation of a second use, was forced into the courts of equity; and this species of trusts, extended by inference and construction, has ever since remained as a kind of *peculiar* in these courts; yet there are other trusts which are cognizable in a court of law. Moreover, it has been said that a court of equity is not bound by rules or precedents, but acts from the opinion of the judge, founded on the circumstances of every particular case. Whereas the system of our courts of equity is a laboured, connected system, governed by established rules, and bound down by precedents, from which they do not depart, although the reason of some of them may perhaps be liable to objection.

In short, if a court of equity in England did really act, as many ingenious writers have supposed it (from theory) to do, it would rise above all law, either common or statute, and be a most arbitrary legislator in every particular case. Formerly, indeed, our courts of equity arrogated to themselves such an unlimited authority as hath totally been disclaimed by their successors for more than a century past. But the systems of jurisprudence, in our courts, both of law and equity, are now equally artificial systems, founded in the same principles of justice and positive law; but varied by different usages in the forms and mode of their proceedings; the one being originally derived (though much reformed and improved) from the feudal customs, as they prevailed in different ages in the Saxon and Norman judicatures; the other (but with equal improvements) from the imperial and pontifical formularies, introduced by their clerical chancellors.

The suggestion indeed of every bill, to give jurisdiction to the courts of equity (copied from those early times) is, that the complainant hath no remedy at the common law. But he, who should from thence conclude, that no case is judged of in equity, when the law might have given relief, and, at the same time, casts his eye on the extent and variety of the cases in our equity reports, must think the law a dead letter indeed. The rules of property, rules of evidence, and rules of interpretation, in both courts, are, or should be, exactly the same; both ought to adopt the best, or must cease to be courts of justice. Neither a court of equity nor of law can vary men's wills or agreements, or (in other words) make wills or agreements for them. Both are to understand them truly, and therefore both of them uniformly.

uniformly. The rules of decision are in both courts equally apposite to the subjects of which they take cognizance. Such then being the parity of law and reason which governs both species of courts, it may be asked what constitutes their essential difference? It principally consists in the different modes of administering justice in each; in the mode of proof, the mode of trial, and the mode of relief. Upon these, and upon two other accidental grounds of jurisdiction, which were formerly driven into these courts by narrow decisions of the courts of law, *viz.* the true construction of securities for money lent, and the form and effect of a trust or second use; upon these main pillars hath been gradually erected that structure of jurisprudence which prevails in our courts of equity, and is inwardly bottomed upon the same substantial foundations as the whole system of law. As to the mode of proof, when facts, or their leading circumstances, rest only in the knowledge of the party, a court of equity applies itself to his conscience, and purges him upon oath with regard to the truth of the transaction; and, that being once discovered, the judgment is the same in equity as it would have been at law. But, for want of this discovery at law, the courts of equity have acquired a concurrent jurisdiction with every other court in all matters of account. From this compulsive discovery upon oath, the courts of equity have acquired a jurisdiction over all matters of fraud. As to the mode of trial, this is by interrogations administered to the witnesses, upon which their depositions are taken in writing, wherever they happen to reside. With respect to the mode of relief, the want of a more specific remedy, than can be obtained in the courts of law, gives a concurrent jurisdiction to a court of equity in a great variety of cases. Thus it is in executory agreements, and in various kinds of frauds, &c. The true construction of securities for money lent is another fountain of jurisdiction in courts of equity. The form of a trust, or second use, gives the courts of equity an exclusive jurisdiction as to the subject-matter of all settlements and devises in that form, and of all the law terms created in the present complicated mode of conveyancing. This is a very ample source of jurisdiction. Blackst. Com. vol. iii.

*EQUITY of redemption*, on mortgages, is that right which a mortgagor has of redeeming his estate upon payment of the money borrowed. This enables a mortgagor to call on the mortgagee who has possession of his estate to deliver it back, and account for the rents and profits received, on payment of his whole debt and interest; thereby turning the *mortuum* into a kind of *vivum vadium*. But on the other hand, the mortgagee may either compel the sale of the estate in order to get the whole of his money immediately, or else call upon the mortgagor to redeem his estate presently, or, in default thereof, to be for ever foreclosed from redeeming the same, that is, to lose his equity of redemption without possibility of recall. And also in some cases of fraudulent mortgages, (stat. 4 & 5 W. & M. c. 16.) the fraudulent mortgagor forfeits all equity of redemption whatsoever. This is done by proceedings in the court of chancery. But the chancery cannot shorten the time of payment of the mortgage money, where it is limited by express covenant, though it may lengthen it; and then upon non-payment, the practice is to foreclose the equity of redemption of the mortgagor. 2 Vent. 364.

To foreclose the equity, a bill in chancery is exhibited, to which an answer is put in, and a decree being obtained, a master in chancery is to certify what is due for principal, interest, and costs, which are to be prefixed by the decree, whereupon the premises are to be re-conveyed to the mortgagor; or, in default of payment, the mortgagor is order-

ed to be foreclosed from all equity of redemption, and to convey the premises absolutely to the mortgagee. Law of Securities, p. 129. 133.

By stat. 7 Geo. II. cap. 20; after payment or tender by the mortgagor of principal, interest, and costs, the mortgagee can maintain no ejectment, but may be compelled to re-assign his securities.

*EQUITY*, in *Mythology*, sometimes confounded with Justice, a goddess among the Greeks and Romans, represented with a sword in one hand and a balance in the other.

*EQUIVALENT*, is understood of something that is equal in value, force, or effect, to another.

Equivalence is of various kinds, in propositions, in terms, and in things.

*EQUIVALENT propositions*. See *EQUIPOLLENCE*.

*EQUIVALENT terms*, are where several words that differ in sound have yet one and the same signification; as "every body was there," and "nobody was absent," *nihil non*, and *omne*.

*EQUIVALENT things*, are either moral, physical, or statical. Moral, as when we say that the commanding or advising a murder is a guilt equivalent to that of the murderer. Physical, as when a man who has the strength of two men is said to be equivalent to two men. Statical, whereby a less weight becomes of equal force with a greater, by having its distance from the centre increased.

*EQUIVOCAL*, *EQUIVOCUM*; denotes a word or expression that is dubious and ambiguous, or that may have several senses, one true and another false.

Equivalent terms answer to what are otherwise called *homonyma*, or homonymous terms.

Such is the word *emperor*, which is both the name of a dignity, the proper name of a person, and the name of a plant. So also the Latin *gallus*, which stands indifferently for a cock and a Frenchman.

In these cases, one word denotes two or more different ideas, or different sorts of objects; whence that common definition of equivocal in the schools, "quorum nomen est commune ratio vero essentia secundum illud nomen diversa." Philosophers distinguish equivocal into active and passive; or *equivoca æquivocantia*, and *æquivocata*.

*Æquivoca æquivocantia*, or those that denominate and signify things, are words common to several things in a very different signification, *i. e.* to several things which have a similar essence correspondent to the similar denominations. *E. gr.* The word *taurus*, which stands for a sign, a mountain, and an animal; and in one signifies a lowing animal; in another, a heap of stones and earth; and in the third, a constellation or system of stars.

*Æquivoca æquivocata*, or those that are called or denominated, are the things signified by ambiguous names, *e. gr.* a sign, a mountain, and an animal; which last species of equivocal alone Aristotle seems to have had in view in his definition, which agrees to these, and these only.

*EQUIVOCAL action and cause*. See *ACTION* and *CAUSE*.

*EQUIVOCAL generation*, is a method whereby animals and plants are supposed to be produced, not by the usual way of coition between male and female, but by some supposed plastic power or virtue in the sun, &c.

Thus, insects, maggots, flies, spiders, frogs, &c. have usually been supposed to be produced by the heat of the sun warming, agitating, and impregnating the dust, earth, mud, and putrified parts of animals.

This method of generation, which we also call *spontaneous*, was commonly asserted and believed among the ancient philosophers; but the moderns, from more and better observations, unanimously reject it, and hold that all animals,

animals, nay, and vegetables too, are univocally produced; that is, from parent animals, and vegetables of the same species and denomination.

It were a thing, one would imagine, sufficient to discredit the Aristotelian, or rather the Egyptian doctrine of equivocal generation, to find flies, frogs, lice, &c. to be male and female, and accordingly to ingender, lay eggs, &c.

The doctrine of equivocal generation we call an *Egyptian doctrine*, as having, in all probability, had its rise in Egypt, to solve the hypothesis of the original production of men, and other animals, out of the earth, by the help of the sun's heat.

To prove which, the Egyptians, as Diodorus Siculus observes, produce this observation, that about Thebes, when the earth is moistened by the Nile, and afterwards impregnated by the intense heat of the solar rays, an innumerable swarm of mice come forth: whence he infers, that all kinds of animals might equally have arisen out of the earth at the beginning of things; and from these bishop Stillingfleet takes the other writers and adherents to the doctrine of equivocal generation, Mela, Pliny, Ovid, &c. to have borrowed the hypothesis without inquiring into its truth. Derham's *Phys. Theol.* lib. iv. cap. 15. See GENERATION.

**EQUIVOCATION**, *ÆQUIVOCATIO*, the using a term or expression that has a double signification.

Equivocations are expedients to save telling the truth; and yet without telling a falsity. The fathers are great patrons of equivocations and mental reservations, holding, that the use of such shifts and ambiguities is in many cases allowable.

St. Augustine, particularly, is reproached with endeavouring to vindicate Isaac for saving his wife from a crime by an equivocation; "tacuit aliquid veri, & non dixit aliquid falsi." To advance a dubious proposition, knowing it will be understood in a sense different from that you give it in your mind, is an equivocation, and a breach of good faith and sincerity.

In moral theology, it is strictly understood of a term or phrase with two different significations, the common and obvious, the other more unusual and remote; the latter of which being understood by the speaker, but the former by the hearers, they conceive something different from one another.

Of this we have an instance in St. John, chap. xi. where our Saviour is represented as saying, "Lazarus sleepeth," for the disciples who took the word sleeping in the usual signification, concluded that Lazarus, whom they had been told, was sick, began to take rest, and would soon recover; but Jesus, using the word in a less direct and usual signification, meant that Lazarus was dead.

When the equivoque consists of several words, it is properly called an *amphibology*, (which see,) of which we have an instance in St. John, chap. ii. "Destroy this temple," says Jesus, speaking to the Jews, "and I will raise it again in three days."

The lawfulness of the use of equivocations has been greatly disputed among the modern casuists; many grave authors deny that it is allowable to use them on any occasion whatever. Their reason is, that an equivoque is to all intents and purposes the same thing with a lie.

**EQUIVOQUE**, *L'*, in *Music*, is when a sharp, by extreme modulation, becomes a flat, and *à contra*. As the chord of D♯ becoming the chord of C♯ with a sharp 3d, &c. See MODULATION, and EXTRANEOUS.

**EQUULEUS**, or **ECULEUS**, in *Antiquity*, a kind of

rack, or engine of torture, used for extorting the truth; at first chiefly on slaves, but afterwards turned against the Christians.

The patient's arms and legs being fastened on the equuleus with cords, he was hoisted aloft, and extended in such manner that all his bones were dislocated. In this state, red-hot plates were applied to his body, and he was also goaded in the sides with an iron-forked instrument, called *ungula*.

The equuleus was of wood, and had holes at certain distances, with a screw, by which the criminal was stretched to the third, sometimes to the fourth or the fifth hole: at intervals, the screw was slackened again, by which he had some respite; but then he was tormented with questions.

The equuleus in more ancient times was constructed in the form of a horse; the criminal was laid on his back, and his arms were turned under the breast of the equuleus, his hands were bound, and his feet stretched out towards his tail. A rope fastened to the feet was made to pass over a smaller pulley between the hind-legs of the equuleus, and made to coil over another larger pulley fixed under the belly by means of a handle, which the executioner turned round till all the bones, &c. were dislocated. See a learned dissertation on the form and use of this instrument, by Dr. Ward, in the *Phil. Transf.* vol. viii. part iv. p. 32, &c.

Hieronimus Magius, when a prisoner among the Turks, wrote an express treatise "De Equuleo;" and another of Bells, merely as it is said from his memory, without any assistance of books. Sigonius had another treatise on the same subject.

**EQUULEUS**, *Equiculus*, and *Equus minor*, *equi scētio*, the *Horse's Head*, in *Astronomy*, a constellation of the northern hemisphere, whose stars in Ptolemy's Catalogue are 4, in Tycho's 4, in Hevelius's 6, and in Mr. Flamsteed's 10. See CONSTELLATION.

**EQUULEUS**, in *Arts and Manufactures*. See HORSE.

**EQUUS**, in *Zoology*, a genus of the *Belluæ* order. The fore-teeth in the upper jaw are six, erect, and parallel; the lower six, and more prominent; tusks solitary, included, remote; teats two, inguinal.

#### Species.

**CABALLUS**. Tail with long flowing hair. *Equus cauda undique setosa*, Linn. *Equus auricularis brevibus erectis, juba longa*, Briss. *ἵππος*. Aristot. *Ælian*, &c. *Equus, equa, equiferus*, Pliny. *Gesn. Aldr. &c. Cheval*, Buff. *Ross*, *Gesn. Horse*.

**FERUS**. α. *equus ferus*, Hasselq. *Wilde Pferde*, Gmel. Pallas. *Tarpany*, Rytfschk. Orenb. *Wild horses*, Bell.

**DOMESTICUS**. β. *equus domesticus*. *Domestic horse*.

This generous animal is cultivated in most parts of the earth, and is found in a wild state in the deserts of Great Tartary, in the southern parts of Siberia, the banks of the river Don, and other parts of Asia and Africa. See HORSE.

**HEMIONUS**. Longitudinal dorsal stripe without humeral transverse band; tail hairy at the tip only. *Equus hemionus*, Pallas Nov. Comm. Petrop. v. 19. Gmel. *Czigitai*, Buff.

This curious animal, described by Pallas in the Transactions of the Royal Academy of Petersburg, is supposed by that naturalist to be the hemionos of Aristotle, and which appears, if this conjecture be correct, to have remained almost unnoticed from the time of Pliny, who mentions it as a native of Cappadocia.

## EQUUS.

The *Czigitai*, or, as more commonly called, *Dshiggetai* in the Mongolian language, is a native of the desert regions between the rivers Onon and Argun, in the southern parts of Siberia, and especially those of Gobi, which extend even to the confines of China and Thibet. The name *Dshiggetai* signifies *Great Ears*, and is given to this species of wild horse, because its ears exceed in proportion the size of those of the common kind. They are, nevertheless, straighter and better formed than those of the mule, to which the whole conformation of the animal bears much similitude. His stature is that of a mule of the common dimensions: the length being more than five feet, and his weight from four to five hundred pounds. The head is large, with an appearance of heaviness, and the front flattened: the eyes moderate, with ash-coloured irides. The mouth is furnished with thirty-four teeth. The neck is slender, and compressed with a soft, short, erect mane, and on the fore-top a tuft of downy hair about two inches in length. The body is rather long; the breast large and protuberant; the back somewhat concave or depressed, with the flanks and posterior part thin, as in the mule. The limbs are long and slender, with an oval callus within the fore legs; the hoofs like those of the ass; and the tail, which is two feet in length, corresponding with that of the cow, in being naked for half its length, and having the tip hairy.

During summer the prevailing colour of this animal is yellowish brown, with the upper part of the head and inner part of the limbs tawny, and sometimes the inside of the hind thighs and belly are said to be whitish. The nose is white; the mane and tail blackish; and the back marked with a line of chestnut or deep black, extending from the mane to the tail. The dorsal line is rather dilated on the loins, and becomes narrower towards the tail. The summer coat is much smoother than that which it assumes in winter, for the hair during the latter season is longer, and changes to a deeper or more ruddy hue, inclining at the tips to grey.

These animals are of a social disposition among themselves, living together in troops of twenty or thirty, or sometimes an hundred. They prefer the open plains, abounding in salt marshes; and never approach the forests nor mountainous situations. Each of these troops is placed under the guidance of a leader, who is constantly on the watch while the rest of the herd is at rest, or feeding; and who, in case of danger, gives the signal of alarm, by leaping and looking steadfastly at the object which excites his fears. This vigilant leader is often killed, because he is stationed at some distance from the herd, and oftentimes approaches still nearer to the hunters, in order to watch them attentively; and when he falls the herd does not disperse till many of them are killed. When alarmed and put to flight the best horses could not overtake them; their swiftness surpasses that even of the antelopes. They have the senses of sight and smell in exquisite perfection. In their manners they are naturally timid, but when closely pressed by an enemy are very fierce, and defend themselves both with their teeth and feet. Their neigh is more shrill than that of a horse. The pregnant females are with young from August till the following spring, when each produces a foal, or rarely two.

The *Czigitais* would form an excellent race of small horses, could they be reduced to a state of domestication, but such is the untractableness of their disposition, that the difficulties of training them for this purpose appear unsurmountable. The people of the vast deserts which they inhabit pursue them only for the sake of their flesh and skin, the former of which they esteem a delicacy.

**ASINUS.** Tail bristly at the extremity; a black cross on the shoulders. Linn. **The Ass.**

This animal is described at length under the article **ASINUS.**

**ZEBRA.** Body pale buff, with perpendicular fuscous bands; limbs transversely striped with fuscous. *Equus zebra*, *fasciis fuscis versicolor*, Linn. *Equus indicus*, Jonst. *Equus brasiliensis*, Jacob. *Zecota*, Ludolf. *Asne de beauté extraordinaire*, Thevenot. *Indianisch Maulthier*, Gessn.

The zebra is one of the most beautiful quadrupeds known; uniting to the grace of the horse, and swiftness of the stag, a peculiar combination of colours, that renders its appearance admirable. This animal is rather larger than the common ass, and bears some resemblance to the mule. The head is of moderate size, and well formed, the ears long, the legs delicate, the body graceful, and the beauty of its shape heightened by the smoothness of the skin. The colour is either milk white, or faintly tinged with brown, or pale ferruginous, and the whole animal adorned with alternate pale and fuscous bands disposed with such amazing regularity as to have rather the appearance of art than nature. The stripes run in a transverse direction both on the body and limbs. The head is striped with fine bands of black and whitish, forming a centre in the forehead. The neck is adorned with stripes of the same, running in the same direction as those on the back, all which point perpendicularly towards the belly. The thighs and legs are fasciated transversely with fuscous. The tail is of moderate length, round, rather slender, marked with blackish bands, and terminated by a thick tuft of brownish hair. The colours in the male are remarkably vivid, being sometimes of a fine yellow or yellowish, with the stripes nearly black, the female is almost white, with the stripes brown.

These animals are found in the hotter regions of Africa, from Ethiopia to the Cape of Good Hope; and are in particular met with in great plenty in the extensive solitary mountainous wastes of the latter tract of country. They live in large herds, and possess much of the manners both of the horse and the ass, are excessively swift and vigilant, and prefer subsisting on the hard and dry herbage their sterile haunts afford, to descending into the more fertile and more frequented plains. The disposition of the zebra is more unmanageable than that either of the horse or ass; and even such as have been taken when very young have evinced the same invincible degree of passion for liberty, when grown up, as those caught at an age of maturity. The Dutch have taken great pains to train them for domestic purposes, but with little success, and which is the more to be regretted as the domestication of these animals would be of essential utility to the colony. This is testified from the actual observations of many travellers.

The zebra, transported into the temperate climates of Europe, have been known to produce young; but their offspring degenerates. It has been known to couple with the Arabian horse, and to give birth to a small mule not very unlike the hybrid creature formed between the horse and ass. According to Sparrmann, the zebra is hunted by the Hottentots for the sake of its flesh, which they deem excellent; but, in reality, it is in no respect superior to that of the horse. Le Vaillant describes the manners of these animals; the cry of the zebra, according to this writer, is very singular.

**QUAGGA.** Above chestnut fasciated with fuscous, sides spotted; belly, legs, and thighs white. *Equus quagga*, Gmel. *Opeagha*, or *quagga*, of the Hottentots. Madson's Travels, Phil. Trans.

The quagga approaches so nearly in resemblance to the zebra, as to have remained till very lately confounded with it, and from various circumstances to be considered as the female. This animal is inferior in size to the zebra. The prevailing

prevailing colour reddish brown, and the upper part is marked with bands of black, but one of the principal differences consists in the belly, legs, and thighs being white, and destitute of bands, as are also the flanks and buttocks. There is an obvious distinction between the two sexes of this animal, the colours of the male being far more vivid than those of the female.

The more solitary regions in the southern parts of Africa are the haunts of this beautiful animal. They are of a social disposition, and in a state of wildness, herd in troops of a hundred or more together; and it is observed that though they inhabit the same deserts as the zebra they never associate with that species. The quagga, unlike the zebra, is of a tractable nature: in size it is smaller, but stronger, and in proportion more robust. The attempts of the colonists of the Cape to reduce this animal to a state of servitude, like the horse, has been attended with some success; an instance of this is mentioned by Sparrmann. Quagga, opeagha, and also *owab*, or *kwab*, are the names by which the Hottentots distinguish this animal; its cry resembles the barking of a dog, in which sounds, similar to the latter words, are frequently repeated. Its flesh, which resembles that of the zebra, is eaten by the natives.

#### Appendix.

*Bifidulus*. Hoofs cloven. Gmel. *Guémul*, or *Huémul*, Molina. Hill. Chili.

The cloven-footed, or Chilese horse, is an animal of very ambiguous character, and which, if our suspicions be well founded, will be removed from the equus tribe whenever naturalists become better acquainted with this supposed species than they appear to be at present. The animal seems to have been unknown till observed by Wallis in the straits of Magellan. Molina, in his "Storia Naturale del Chili," describes it as a horse, under the title of *Guémul* or *Huémul*, and, as later writers depend on the authority of Molina for their description of this anomalous animal, it may not be amiss to repeat the particular information his account affords us. The guemul is described by him as resembling in different respects both the horse and the ass; it bears an affinity to both, but cannot appertain to either; the division of the hoofs alone being sufficient to remove it from these apparently congenerous animals. In point of stature and appearance, the texture of the hair, and colour, the guemul, according to Molina, resembles the ass. The form and disposition of the teeth correspond with those of the horse. The ears are not long, as in the ass; they are short, straight, and pointed, as in the horse; neither is the back or shoulders of the guemul marked with the black stripe by which the ass is usually distinguished. The head is better formed than that of the ass, the chest more elegant, and the tail and buttocks more graceful. The internal conformation affords the most obvious diversity; and the voice, dependant, in a material degree, on this interior organization, rather resembles the neighing of the horse than the bray of the ass. Gmelin is not correct in his translation from Molina, when he describes the "structura interna," &c. as corresponding with that of the ass; this point may be thought material to the development of the true character of the animal, and should be therefore mentioned; and the more especially since the same mistake prevails in all the English descriptions of this cloven-footed, or Chilese horse, that we have seen.

Molina speaks of the guemul as an animal of a vicious nature, wild, and of surprizing velocity. It inhabits the heights of the most inaccessible mountainous regions of the

Andes of Chili; and it is said, besides, to be found in other Alpine tracts of South America.

The information upon which this animal is described appears to be not sufficiently explicit. We think the guemul ought not to be retained with the horse or equus tribe. Perhaps it is of the camelus tribe, or that, with still more propriety, it ought to be allowed to constitute a new genus. An ingenious writer observes, that "if only a single specimen of this animal had been described, we might have hesitated as to admitting it otherwise than as an accidental variety." We could have wished the other authorities alluded to had been adduced. The continental naturalists offer argument and speculation dependant on the description given by Molina only; any farther information would therefore prove acceptable. In the Gmelinian "Systema Naturæ" this animal is classed as a horse. Sonnini considers it as allied to the lama, or camelus glama, and camelus vicugna. According to the character "pedes ungula indivisa," established by Linnæus for the equus genus, nothing can be more absurd than a cloven-footed horse. Its affinity to the camel appears rather more evident, or, as before intimated, if it be not of that tribe, it is not improbable that it may constitute a new genus.

*Equus Marinus*, in *Ornithology*, the *Fulmar* of Pennant and Latham, and the *PROCELLARIA Glacialis* of other writers, which see.

*Equus Marinus*, in *Zoology*, a name given by some to an animal very different from the hippopotamus, or river-horse, and more usually known by the name of the *Marje*. See *TRICHECHUS Rosmarus*.

ERA, in *Chronology*. See *ÆRA*.

ERA, in *Geography*, a river of Tuscany, which runs into the Arno; 14 miles above Pisa.

ERABA, a town of Persia, situated on the eastern bank of the river that answers to the Arabius of Alexander and Nearchus.

ERACLISSA, in *Botany*, so named by Forskall, from the Greek village near which he gathered it, is according to Jusseu, no other than *Audrache telephioides* of Linnæus. See Forsk. Fl. Ægyptiaco-Arab. 208.

ERACTUM, in *Ancient Geography*, a town of European Sarmatia, in the country of the Baltharæ, according to Ptolemy. It has been thought to be the modern *Row*, a small town of Podolia.

ERADICATIVE, in *Medicine*. See *RADICAL*.

ERÆ, in *Ancient Geography*, a small maritime, fortified town of Asia Minor, in Ionia, according to Strabo, who says that it was either founded or possessed by the Teians.

ERAGI, a town of Africa, in the Pentapolis, according to Ptolemy.

ERAGISA, RAJIK, a town of Syria, in the Cyrrhastii territory, upon the banks of the Euphrates, according to Ptolemy, situated S. S. E. of Hierapolis.

ERAGROSTIS, in *Botany*, from ερα, *love*, and αγραστis, *grass*, the name of an elegant grass, *Poa Eragrostis* of Linnæus, called in Latin *Gramen Amoris*, and in French *Amourettes*. See Sm. Fl. Græc. Sib. t. 73, where the Linnæan *Briza Eragrostis* is given as a synonym.

ERANA, in *Ancient Geography*, a borough of Asia, in Cilicia; being the chief place of mount Amanus, upon which it was situated; on the same side with the altars of Alexander. Cicero says it resembled a town rather than a village.

ERANARCHA, formed of εραρος, *alms*, *contribution*, and αρχη, *command*, a public officer among the ancient Greeks, whose business was to preside over and direct the alms given, and provisions made for the poor.

The eranarcha was properly the administrator or steward of the poor: when any person was reduced to poverty, taken captive, or had a daughter to marry, which he could not effect for want of money, &c. this officer called an assembly of friends and neighbours, and taxed each, according to his means and estate, to contribute towards his relief. This is what we learn from Cornelius Nepos, in his life of Epaminondas.

ERANG, in *Geography*, a town of the island of Ceylon.

ERANGELIA, in *Botany*, (*Ἡραγγελία*, the herald of spring), a name given by Rensselm in his *Specimen Historiæ Plantarum*, 97, to the Snow-drop. See GALANTHUS.

ERANNA, in *Ancient Geography*, a town of the Peloponnesus, in Triphylia, a province of the Elide. Strabo calls it *Erana*, and places it between Cyparissia and Pylus.

ERANNOBOAS, or ERRANOBOS, a river of India, according to Arrian; situated within the Ganges, into which it discharged itself near the town of Palibothra. This river was of the third degree of magnitude among the Indian rivers, and inferior to none but the Ganges and Indus. Major Rennell cannot apply the name Erranobos to any particular river. Pliny certainly says, that the Jomanes (Jumnah) entered the Ganges by Palibothra, between Methora and Clifobara (otherwise Caryfobora and Cyrifoborea): but it is equally true, that in another place he mentions the conflux of the Ganges and Jomanes, and in the very next article says that Palibothra is situated 425 miles below that very point of conflux. Strabo does not give the name of the adjoining river. See PALIBOTHTHA.

ERANTHEMUM, in *Botany*, from *ἔρα*, the earth, and *ἄνθος*, a flower, according to Linnæus (*Phil. Bot.* 177.) who is the author of the name; but such a derivation is, in the present instance, wholly destitute of any appropriate meaning. We should have supposed it rather from *ἔρα*, love, on account of the beauty of the flower, which might well justify such a denomination; and it is not impossible that Linnæus might have had this idea in his mind when he wrote the *Flora Zeylanica*, but forgot it when composing his *Philosophia Botanica*. Linn. *Fl. Zeyl.* 6. *Diff. Nov. Gen. Pl.* 1. *Am. Acad.* v. 1. 334. *Gen. Pl.* ed. 4. 418. cl. 6. 11. Schreb. 15. Willd. *Sp. Pl.* v. 1. 51. Mart. *Mill. Dict.* v. 2. *Juss.* 110.

*Gen. Ch.* Cal. Perianth five-cleft, tubular, very narrow, erect, short, pointed, permanent. Cor. of one petal; funnel-shaped; tube very long and thread-shaped; limb deeply five-cleft, (occasionally four-cleft), flat, its segments obovate. *Stam.* Filaments two, very short, in the mouth of the corolla; anthers nearly ovate, compressed, projecting beyond the tube. *Pist.* Germen ovate, minute; style thread-shaped, reaching to the top of the stamens; stigma simple. *Peric. and seeds* not known. Linnæus adds, that he had seen only a single specimen, (which by the mark †, was a dried one), and therefore he left the genus to the attentive examination of other botanists.

*Ess. Ch.* Corolla five-cleft; tube thread-shaped. Anthers projecting beyond the tube. Stigma simple. Fruit . . .

Such are the characters given by Linnæus, and copied by Schreber, but the plant whence they were taken being other than a *Jussiaea*, very near, if not the same with *J. palebella*, Roxb. *Corom.* t. 177, *Erantlemum* falls to the ground. Linnæus indeed, in his own *Gen. Pl.* has made the following manuscript corrections: that the two upper segments of the calyx are the shortest; segments of the corolla not obovate but oblong, two of them joined together; anthers within the mouth of the tube.—Whence

these corrections were taken we have no knowledge; probably from some of the plants he subsequently referred to *Erantlemum*, for he certainly never again saw the specimen he originally described from Herman's herbarium, nor had he in his own any thing to illustrate the subject. In the *Species Plantarum* one species only is mentioned, by the name of *E. capense*, said to grow in Ethiopia, and to have the habit of a *Chironia*; yet he comprehends under it the plant of his *Flora Zeylanica*, which, as we have said, is a *Jussiaea*, and with this last the synonyms of Herman's *Paradilus*, Amman and Ray have certainly no connection. In the thirteenth and fourteenth editions of the *Systema Vegetabilium* *Selago dubia* of Sp. Pl. having but two stamens and its fruit not ascertained, is called *Erantlemum angustifolium*; while another species, called *parvifolium*, is adopted from Bergius, along with a synonym of Commelin, who figures it with four stamens and all the aspect of a *Selago*: indeed Linnæus, in his own copy of Bergius, has expressed a suspicion of its being such. *E. falsoides*, from *Teneriffe*, the only supposed species besides is described in the *Suppl. Pl.* but wholly unknown to us. How far the above, and other spiked species of *Selago*, may constitute a genus by themselves, as Jussieu suspects, we must leave in doubt; but if so, they cannot have any thing to do with the name or the above generic characters of *Erantlemum*. S.

ERANUSA, in *Ancient Geography*, a small town of Italy, placed by Pliny near the promontory of Lavinium.

ERARIUM. See *ÆRARIUM*.

ERAS, in *Ancient Geography*, a town of Asia Minor, in Ionia, in the vicinity of Ephesus, according to Thucydides.

ERASED, in *Heraldry*, expresses any thing that seems violently torn off from its proper place. It is used in contradistinction to couped, which signifies a thing clean cut off. The family of Card bears ermine, a demy lion rampant erased, azure, &c.

ERASINUS, in *Ancient Geography*, a river of the Peloponnesus, in Arcadia, according to Strabo, who says that this river had its mouth near Bura, in the gulf of Corinth.—Also, a river of Greece, in Eretria. Strabo.—Also, a river of Greece, in Attica, near Brauron. Strabo.—Also, a river of Asia Minor, in Lycia.—Also, a river of the Argolide, towards the S. E. of Cenchrea, which formed a confluence with the Phryxus.

ERASISTRATUS, in *Biography*, a physician of great reputation among the ancients, but of whose parentage and birth-place, as well as of the æra in which he flourished, different accounts have been transmitted to us by different writers. It appears most probable, however, that he was born at Julis, in the isle of Cea or Ceos, (and not in Cos, the birth-place of Hippocrates, as has been asserted,) that he was the most distinguished pupil of Chrysippus, the Cnidian physician, and had attained a high character in his profession in the 123d olympiad. His fame acquired him the notice and esteem of Seleucus Nicanor, king of Syria, at whose court he is said to have evinced his sagacity in the following manner. Antiochus, the king's son, was seized with a severe malady, and the most ingenious physicians of the time were unable to discover the cause of it; until Erasistratus, observing the prince most attentively, remarked, that whenever Stratonice, his father's second wife, entered his apartment, he became considerably agitated, a blush suffused his countenance, his voice grew more feeble, and his pulse quickened:—whence the physician decided that his disorder was the effect of a concealed passion for Stratonice. In order to inform the king of this delicate affair, he stated that

## ERASISTRATUS.

Antiochus's disease was the result of a passion, the more unfortunate as it could not be gratified. The king, surprised at the impracticability of gratifying the inclinations of his son, demanded eagerly who was the object of his love. "My wife," replied Erasistratus, promptly. Seleucus having urged him strongly not to occasion the death of his son, by refusing to give up his wife, Erasistratus inquired, if he would give up Stratonicæ to save his son's life, were she the object of his affection; with which the king expressed his ready compliance, and Erasistratus vowed that this would be the only means of preserving the life of Antiochus. Seleucus immediately declared him king of the provinces in Upper Asia, and gave him Stratonicæ in marriage, although she had already had one child.

The great character of Erasistratus, however, is founded upon more solid ground than this anecdote displays. He may be considered as the father of anatomical science, at least conjointly with Herophilus. It seems to be clearly established, that, before the time of these physicians, no one had dared to dissect human bodies; anatomical examinations had been confined exclusively to the bodies of brutes. Human bodies had, indeed, been opened for the purpose of embalming, among the Egyptians, but no anatomical inquiry had resulted from that practice. The Ptolemies, especially Soter and Philadelphus, being desirous that the arts should be cultivated, and having surmounted the prejudices of the age, granted the bodies of malefactors to the physicians for dissection, of which opportunity Erasistratus and Herophilus availed themselves largely, and made several important discoveries. To what extent these discoveries were carried, it is not easy to ascertain, since the works of these physicians are lost; and what we learn respecting them is chiefly through the medium of Galen, who deeming Erasistratus in some sort a rival of his idol, Hippocrates, seldom quotes him but to confute him. It is asserted by Celsus (*De Medicinâ, Præfat.*), that the monarchs above-mentioned took the condemned criminals from prison, and gave them up to Erasistratus and Herophilus, who dissected them alive, in order to obtain a more accurate knowledge of the vital motions. (*See EMPIRIC.*) It has been doubted, however, whether they were guilty of this barbarous practice, in consequence of their adoption of the opinion of Praxagoras, that the veins only received blood, and the arteries, and left ventricle, air; since, if they had opened the living body, they must have had ocular demonstration of the existence of blood in the latter: and this imputation is supposed to have been thrown upon them in a fabulous age; just as Medea is said to have boiled living men, because she was the first who practised warm bathing. (*See Eloy Dict. Hist.*) It would appear, however, from the statement of Galen, that the evidence of their senses, upon this subject, was contravened by this sort of subterfuge: "as soon as the left ventricle of the heart is opened," they observed, "the air is dissipated, and the ventricle is instantaneously filled with blood." (*Galen, an sanguis sit naturâ in arteriis.*)

Erasistratus and Herophilus were the first who dissected the human brain accurately; according to the fragments preserved by Galen, Erasistratus described the brain minutely, its convolutions, the division of cerebrum and cerebellum, its cavities or ventricles, with their passages of communication, and the origin of the nerves; and he inferred that the brain was the common sensorium, or source of all the vital actions and sensations, which were effected through the medium of the nerves. (*Galen, De Hippoc. et Platon. decret. lib. vii. cap. 3.*) He also examined minutely the structure of the heart and of the great vessels, and was the first to point out the valvular apparatus, and its peculiar form in each of

the cavities of that viscous. (*Loc. cit lib. i. cap. 10. and lib. vi. cap. 6.*) He affirmed that the veins divided in the liver, for the purpose of secreting the bile; and knew that the urine was secreted by the kidneys.

His physiology, in general, was not, however, very profound, and his pathology necessarily imperfect; although he attempted to explain the causes of diseases from his knowledge of the structure of the body. The function of respiration served, in his opinion, merely to fill the arteries with air. "The thorax being dilated," he said, "the lungs expand at the same time, and receive air: this air passed to the extremities of the divisions of the trachea, and from them into the extremities of the pulmonary artery, whence it is pumped into the heart, by the dilatation of that organ, in order to be distributed to all parts of the body, by the great artery." He attributed digestion to attrition produced by the coats of the stomach; but he did not attempt to explain the particular manner in which the stomach accomplished such attrition.

The hypothesis, by which Erasistratus attempted to explain the origin of inflammation, resembled, in its leading feature, that modern supposition, which, sanctioned by the name of Boerhaave, was generally received in the medical world for a long series of years. (*See ERROR loci.*) He maintained, as we have already stated, that the great vein (*vena cava*) was the reservoir of blood, and the great artery (*aorta*) the reservoir of air. "These reservoirs are divided and subdivided," he affirmed, "until they arrive at the surface, where the ramifications become so minute, that the blood cannot pass farther. Here the mouths or extremities of the arteries and veins close to each other, but the blood continues within its proper bounds, and does not enter the arterial or air-vessels, so that the body continues in the natural state. But when any cause of violence occurs to disturb this regularity, the blood is insinuated into the arteries, and hence the origin of diseases. Among the causes of disturbance just alluded to, too great abundance of blood is the principal; for by it the coats of the veins are preternaturally dilated, and their extremities, which are ordinarily impervious, open, and admit of the passage of the blood into the arteries. This transfused blood becomes an impediment to the course and motion of the arterial spirit or air, which is sent from the heart; and if the opposition of the two matters is direct, or if the blood be arrested near a vital part, a fever is produced; but if the air repel the blood, so that it pass not farther than the extremity of the artery, inflammation of that part is the consequence." (*Galen, de venâ sect. advers. Erasistratum.*)

The practice of Erasistratus, like that of his master Chryssippus, was extremely simple. He did not employ blood-letting, nor purgatives; considering the former as hazardous in the operation, and debilitating in its effects, and the latter as not bringing away the proper humours of the body, but humours in a sort of corrupted state. He sometimes employed glysters, but these of the mildest qualities. All these remedies operated, in his opinion, by reducing plethora, which might be effected more safely and naturally by fasting, or abstinence in diet, especially when aided by exercise. He advised his patients, therefore, to use such articles of diet as contained little nutriment, as melons, cucumbers, and vegetables in general. He was exceedingly averse from the employment of compound medicines, and especially of the mixture of mineral, vegetable, and animal substances; and he exclaimed against the use of the antidotes of the physicians of his day, in which simplicity was altogether shunned.

From the fragments of his writings to be found in Galen and

and Cælius Aurelianus, it would appear, that Erasistratus wrote an accurate treatise on the dropsy, in which he disapproves of the operation of tapping; and that he had left other books on the following subjects:—*viz.* on the Diseases of the Abdomen, on the Preservation of Health, on wholesome Things, on Fevers, and Wounds, on Habit, on Palsy, and on Gout.

Having lived to extreme old age, and suffering severely from the pains of an ulcer in the foot, Erasistratus is said to have terminated his existence by swallowing the juice of cicuta, or hemlock. See Le Clerc, *Hist. de la Médecine*, Eloy, *Dict. Hist. Cælius Aurcl.*

ERASMUS, DESIDERIUS, a man of great celebrity in the republic of letters, was born at Rotterdam on the 28th of October, 1467. He was the natural son of Gerard, a native of Tergou, by Margaret the daughter of a physician, whom he intended to marry, but being deceived by a report of her death, he entered into the church, and on this account Erasmus has been called, by way of reproach, the son of a priest, though his father was not in orders at the time of his birth. When Erasmus was about nine years old he was sent to school at Deventer, where he made very considerable progress in learning, and was particularly distinguished by the excellence of his memory. His mother, who followed him to Deventer, to watch over his health, died of the plague when he was about 13 years of age. He was now left an orphan, and his guardians, forgetful of the sacred trust reposed in them, forced him into the church with a view of embezzling his property. Erasmus resisted their importunity for a considerable time, but at length, when he was nineteen years old, he entered among the regular canons in the monastery of Stein, near Tergou. He was of a delicate constitution, and his health was not sufficiently robust for the life of a monk. His temper and sentiments were likewise averse from the habits of the profession; he accordingly, with the leave of his superiors, accepted, in his 23d year, an invitation to reside with the archbishop of Cambray; but finding the patronage of that prelate not equal to his expectations, he went to Paris and studied in the college of Montaigne. Here he supported himself by giving private lectures to those who were less advanced in their learning than himself. His necessities required great exertion, and thus he acquired habits of industry which raised him to the highest pitch of literary excellence. Some of his pupils at Paris were the sons of Englishmen of considerable consequence, by whose liberality and earnest request he visited their country, and contracted many valuable friendships. This was in the year 1497; from England he went to Italy, continued a year or more at Bologna, from thence to Venice, where he published his *Adagia*; afterwards to Padua, and at last he visited the capital, Rome, where his reputation was very high, and where he might have settled to great advantage, had he not determined, at the entreaties of his friends, and by the express invitation of Henry VIII. to return to England. Henry, while prince, had contracted a friendship and high respect for Erasmus, and in a few months after he succeeded to the crown, we find Erasmus at the court of London high in favour with the monarch, with Wolsey, with the archbishop of Canterbury, and with other persons of distinction.

At first he lived with sir Thomas More, under whose roof he wrote his "*Morizæ Encomium*," or "*Praise of Folly*," a witty and satirical composition. He afterwards went to Cambridge, and read lectures to the students in Greek and theology. For this he was remunerated with a living and many valuable presents, though not of so substantial a nature as to satisfy his expectations. He wished for an

independency, and not being able to secure that in England, he went over to Flanders in 1514, and was shortly after created nominal counsellor to prince Charles of Austria, with a stipend. Soon after this he paid a visit to Basil, where he formed an intimacy with some valuable friends, which induced him to spend his latter days in that place. At Basil he published, in the year 1516, his New Testament, in Greek and Latin, which was received with the utmost eagerness by all those whose minds were turned to theological pursuits. It was dedicated to Leo X. In the course of the same year, his edition of St. Jerome, a favourite author, made its appearance, which he inscribed to his generous patron, archbishop Warham. Erasmus was ever inimical to that system of war which in his time, as in ours, was but too much in fashion among the ambitious rulers of mankind; he published, in 1517, a work entitled "*Querela Pacis, undique gentium ejectæ profligatæque*," which is written with much strength of reasoning and true eloquence. By his contemporaries he was charged with maintaining the unlawfulness of war on all and every occasion: this, however, was a calumny invented by his enemies, of whom he had many, for, in the work alluded to, he expressly says he is speaking only of wars undertaken on trifling and unjustifiable occasions. "I think," says he, "very differently of wars, which are strictly and purely defensive, such as with an honest and affectionate zeal for the country, repel the violence of invaders, and at the hazard of life, preserve the public tranquillity." He was aware of the horrors and atrocities of a state of warfare, and thought almost any sacrifice might be made by wise princes to prevent it. He undertook to vindicate the cause of peace, whom he makes the speaker on this occasion. But the arguments which he puts into her mouth, and the persuasive eloquence with which she addresses the sovereign princes of those dark times, as they are sometimes called, would scarcely be borne by the monarchs of Europe in this enlightened age. His descriptions are vivid, and his reflections but too just: "*Exuruntur vici, vastantur agri, diripiuntur templa, trucidantur immeriti cives, dum princeps interim otiosus ludit aleam, dum saltitat, dum delectat se morionibus, dum venatur, dum amat, dum potat. O Brutorum genus jam olim extinctum! O fulmen Jovis aut cæcum aut obtusum.*" To whom this is particularly applied it does not appear, but the "*Querela Pacis*" was occasioned by the following remarkable circumstance:

It was a favourite project at this period to assemble a congress of kings at Cambray, consisting of the emperor of Germany, the kings of France, England, and the Low Countries; "of which," says the author, "I am a native. They were to enter into mutual and indissoluble engagements to preserve peace with each other, and throughout Europe. This momentous business was very much promoted by William a Ciervia, and by one, who seemed to have been born to advance the happiness of his country, and of human nature, John Sylvagius, chancellor of Burgundy. But certain persons, who get nothing by peace, and a great deal by war, threw obstacles in the way which prevented this truly kingly purpose from being carried into execution. After this great disappointment, I sat down and wrote, by desire of Sylvagius, my *Querela Pacis*." This work was dedicated to Philip of Burgundy, bishop of Utrecht, who was likewise a zealous promoter of peace, and who, so far from being offended with the free sentiments of the book, thanked the author, and even pressed him to accept a living, as a remuneration, which he civilly refused. Erasmus sought no preferment, though, says his biographer, he merited the highest: he sought the happiness of his fellow creatures, and felt himself abundantly rewarded by his own conscience,

and their approbation. The bishop, however, in token of his high esteem, sent him a most beautiful ring, set with a sapphire, which his own brother, his predecessor, in the bishopric, had constantly worn, and which he desired Erasmus to wear for his sake.

The commencement of the reformation, under Luther, was a circumstance of considerable importance in the life of Erasmus. He had thence himself inimical to the superstitions of the times, he had arranged the principles and practices of the monks, and had done much to undermine the whole system of popery, and to expose the various frauds which had been attached to its observance by avaricious and licentious priests; yet he was not prepared to join the reformers as such, his zeal was not sufficient to enable him to endure persecution: he did not wish to break openly from the church, nor was he quite satisfied with the doctrines of the reformers, and still less was he disposed to coincide with the rudeness, vulgarity, and contempt of polite literature which characterized some of that class of people. It has also been said that he was very desirous of being noticed by the great, that he had habituated himself to that degree of indulgence, which would render the prospect of poverty and imprisonment absolutely insupportable to his mind. His income likewise arose almost entirely from pensions which he received from crowned heads, prelates, and men of consequence belonging to the Catholic persuasion, which he would unquestionably have lost had he gone over to the opposite side. These are the reasons which have been assigned why Erasmus did not come boldly forward in defence of the reformation; but with these deductions there is enough in his character to challenge the admiration and gratitude of the friends to liberty and the human race. He was ever the undaunted advocate of free enquiry, and perpetually waged war against the ignorance and bigotry that characterized the age in which he lived. On these accounts he was, in the first years of the reformation, highly regarded by Luther, and it was owing to some unadvised, and, probably, unwarranted attacks made upon Erasmus, about the year 1520, by the zealous reformers, that he was driven to enlist among the defenders of the church of Rome.

In the year 1522, he published his "Colloquies," which, though apparently intended for young persons, were generally read, and are supposed to have been very efficacious in promoting the principles of the reformation. As soon as their tendency was discovered, the clergy attempted to stop their sale, but it was then too late; more than twenty thousand copies of them were disposed of in Paris, besides a number of editions which were printed and sold in other places.

In 1524, Erasmus published his treatise, "De Libero Arbitrio," which was an avowed attack upon Luther's opinion concerning predestination, but the author, in his zeal, spoke against reformers in general; Luther replied, and had unquestionably the best of the argument: in some passages he seemed to commiserate the case of his antagonist, and to regret the necessity that he was under of exposing him. "We saw," says he, "that the Lord had not conferred upon you the discernment, the courage, and the resolution to join us in opposing those monsters, and therefore we dared not to exact from you that which greatly surpasses your strength and capacity." He then refers to the motives of worldly interest by which Erasmus had suffered himself to be swayed from the path of rectitude. The controversy increased in violence, and much unjustifiable acrimony proceeded from the pens of the disputants. Under the article REFORMATION we shall have occasion to enter more at large into this subject, and also into the controversy between Erasmus and Melancthon.

Another antagonist with whom our author had to contend was Julius Cæsar Scaliger, who had put himself at the head of those who were so fastidious in the use of pure Latin as to reject every word not to be found in the works of Cicero, and who on that account had assumed the title of "Ciceronians." Erasmus, superior to this pedantry, employed new words for new ideas, and in justification of his conduct published, in 1528, a dialogue entitled "Ciceronianus," in which he attacked the sect both with argument and ridicule. Scaliger wrote against him with all the malignity that human wit and learning could devise, and he was backed in his scurrility by others of the Ciceronians less able in the warfare, but not less inveterate than their master. The nature of this controversy is fairly exhibited in the notes on the life of Erasmus by Bayle.

Erasmus, wearied, perhaps, by disputation, published, in a short time after his "Ciceronianus" had made its appearance, a treatise of much ability and learning, entitled "De Recta Latini Græcique sermonis Pronunciatione." In the year 1529, Erasmus left Basil for Friburg, in order to shew his attachment to the church which had for some years been losing ground in Basil, and so completely had the reformed religion gained an ascendancy there at this period, that all the images were taken from the town-house and other public places and burnt, which was supposed to have been the means of putting an end to the differences among the common people. Erasmus was now advancing in life, and seemed, more than ever, fearful of being thought friendly to the reformation, and to shew his zeal for the opposite system he wrote and published an epistle against some "who falsely call themselves Evangelists," and as they, from his former works, had produced his authority against persecution, he began to maintain that there were certain cases in which they might lawfully be punished capitally as blasphemers and seditious persons. Such were the unworthy steps to which he was led by an anxiety to keep on good terms with his patrons and protectors.

In 1535 he returned to Basil, and so highly was he esteemed by the church of Rome, that there was an intention to give him a place in the college of cardinals; but it was too late for him to accept of the high honour. His health rapidly declined, and on July 12, 1536, he died of a dysentery at the age of sixty-nine. He was buried with great funeral pomp in the cathedral church of Basil, where his tomb still remains. By his will he left legacies to several friends, and the residue of his property he devoted to charitable purposes. In person he was below the middle size, well-shaped, of a fair complexion, with a cheerful countenance, a low voice, and agreeable elocution. He had assumed the name of Erasmus in conformity with the pedantic taste then prevailing among men of letters of taking names of Greek or Latin etymology; he translated his name of "Gerard," signifying "Amiable," into the equivalent ones of "Desiderius" in Latin, and "Erasmus" in Greek, making use of both, but the latter was his common and perpetual appellation.

Erasmus was a voluminous writer; and his works were published in nine volumes folio. They consist of numerous translations from the Greek; of grammatical and philological pieces; of poems, declamations, and orations; of a collection of adages and apophthegms; of works in divinity on various topics, moral, didactic, and controversial; of a version of the New Testament, paraphrases of the gospels and the epistles, and commentaries on some other parts of scripture; and of apologies, epistles to correspondents, &c. A new and handsome edition of his works was published in Holland by Le Clerc in eleven volumes folio,

1703. Dr. Jortin, the biographer of Erasmus, speaking of his Latin style, says, it "is that of a man who had a strong memory, a natural eloquence, a lively fancy, and a ready invention, who composed with great facility and rapidity, and who did not care for the trouble of revising and correcting; who had spent all his days in reading, writing, and talking Latin; for he seems to have had no turn for modern languages, and perhaps he had almost forgotten his mother-tongue. His style, therefore, is always unaffected, easy, copious, fluent, and clear; but not always perfectly pure and strictly classical."

No one contributed so much as Erasmus to throw discredit upon the barbarism and ignorance of the schools, or to make literature agreeable, and connect it with good sense and solid criticism. He was a great public benefactor; and therefore he is justly regarded as one of the principal glories of his age and country. His memory is equally honoured at the place of his birth and of his death. Several of his relics are preserved at the latter place, and at the former, the house in which he was born, is marked with an inscription, and his statue decorates the great square. Jortin's life of Erasmus. Bayle. Complaint of Peace. 1802.

ERASMUS, in *Geography*, a mountain of the island of Ceylon; 30 miles N.W. of Trincomaly.

ERASTIANS, in *Ecclesiastical History*, a religious sect or faction, which arose in England during the time of the civil wars, thus called from their leader, Thomas Erastus, a German divine of the sixteenth century, whose distinguishing doctrine was, that the church had no right to discipline, that is, no regular power to excommunicate, exclude, censure, absolve, decree, or the like.

According to the founder of this sect, the pastoral office was only persuasive, like a professor of the sciences over his students, without any power of the keys annexed. The Lord's supper and other ordinances of the gospel were to be free and open to all. The minister might dissuade the vicious and unqualified from the communion, but might not refuse it, or inflict any kind of censure; the punishment of all offences, either of a civil or religious nature, being reserved to the magistrate. The pretended advantage of this scheme was, that it avoided erecting *imperium in imperio*, or two different powers in the same civil government; it effectually destroyed all that spiritual jurisdiction and coercive power over the consciences of men, which had been challenged by popes, prelates, presbyteries, &c. and made the government of the church "a creature of the state." Most of our first reformers adopted these sentiments so far as to maintain, that no one form of church government is prescribed in scripture as a rule for future ages, as Cranmer, Redmayn, Cox, &c. and archbishop Whitgift, in his controversy with Cartwright, delivers the same opinion. The Erastians formed a party in the Assembly of Divines in 1643, and the chief leaders of it were Dr. Lightfoot, Mr. Colman, Mr. Selden, and Mr. Whitlock; and in the house of commons there were, besides Selden and Whitlock, Oliver St. John, esq., sir Thomas Widdrington, John Crew, esq., sir John Hipley, and others of distinguished reputation. In the assembly, the Erastians did not except against the presbyterian government as a "political institution," proper to be established by the civil magistrate, but they were against the claim of a "divine right." Accordingly the clause of divine right was lost in the house of commons. Neal's Hist. Purit. vol. ii. 4to.

ERASTUS, THOMAS, in *Biography*, a physician, was born, in 1523, at Auggenen, a village in the district of Badenweiler, in Switzerland. He studied at Basil, where he was seized with the plague in 1542, and narrowly escaped

death. He suffered a long and tedious convalescence, which, together with his poverty, threw an almost insurmountable impediment in the way of his studies; but he fortunately found a generous protector, who opened the door of the sciences to him, and furnished him with the means of travelling to Italy. He took up his residence at Bologna, where his proficiency in the study of philosophy and medicine was such, that he obtained the honour of the degree of doctor of these two sciences. Finding himself in a short time holding a distinguished situation among the men of learning, he followed the custom of the times by changing his name; giving a Greek turn to his original name, which was Lieber, (beloved,) he called himself Erastus. Under this appellation he became a teacher of medicine at Heidelberg, where he obtained considerable reputation; and in 1581 he was called to fill the medical chair in the university of Basil. But this honourable situation he did not long enjoy; he died on the 1st of January, 1583.

He left many works behind him, of which some were printed during his life, and others have been published since his death; their contents, however, are not particularly interesting; the following is a list of their titles and editions. "Disputationum de Medicina nova Philippi Paracelsi," p. i. Basil, 1572, p. ii. ibid. 1572, p. iii. ibid. 1572, p. iv. et ultima, ibid. 1573, all in 4to. In these volumes he refutes the doctrines which Paracelsus had previously taught at Basil, and had committed to writing. 2. "De Causa Morborum Continente," 4to. 1572. 3. "De Occult. Pharmacorum. Potestatibus," 4to; ibid. 1574; Francofurti, 1611. 4. "Disputat. de Auro Potabili," 4to. Basil, 1578, 1594. 5. "De Putredine Liber," 4to. ibid. 1580; Lipsiæ, 1590. 6. "Epistola de Astrologia Divinatrice," 4to. Basil, 1580. 7. "De Pinguedinis in Animalibus Generatione et Concrecione," 4to. Heidelbergæ, 1580. 8. "Comitis Montani, Vicentini, novi Medicorum censoris, quinque Librorum de Morbis nuper Editorum Viva Anatomie," 4to. Basil, 1581. 9. "Ad Archangeli Mercenarii Disputationem de Putredine responsio," 4to. ibid. 1582. 10. "Varia Opuscula Medica," folio, Franc. 1590. See Eloy Dict. Med. Biog. Dict.

ERATO, from *εραω*, *I love*, in *Mythology*, the name of one of the nine Muses who presided over love-poetry. "By Erato," says Callimachus in his epigram on the nine Muses, "the pious hymn was made." To this Muse some have ascribed the invention of the lyre and lute; but particularly the psaltery or long lyre of nine strings; and she is represented with a garland of myrtles and roses, holding a lyre in one hand, and a bow in the other, and at her side a Cupid with his torch. In the portraits of Apollo and the Muses, dug out of Herculaneum, Erato is exhibited holding a plectrum or bow in her right hand, and seeming to play with the fingers of her left. The psaltery, or lyre, is more than twice the length of that in the hand of Terpsichore. (See MUSES.) There is also a Nereid of the same name.

- ERATONOS, in *Ancient Geography*, islands of the Arabic gulf. Pliny designates their aridity by the epithet *Sitientes*.

ERATOSTHENES, in *Biography*, an eminent Greek mathematician, philosopher, and chronologist, was born at Cyrene in the second year of the 126th olympiad, or 275 B. C. He was educated under Aristotle, the philosopher of Chios, and Callimachus, the poet; and he himself had several disciples who were eminent, and among the number was Aristophanes of Byzantium, one of the most celebrated grammarians of his time. Such was the fame of Eratosthenes as a man of extensive erudition, that he was denominated *πρωτελλος*, *i. e.* victorious in five contests, alluding

to the five prizes of the Olympic games, and expressing his pre-eminence in all kinds of literary pursuits. He was also styled the cosmographer and father of chronology, the measurer of the universe, and the second Plato. On the invitation of Ptolemy Euergetes, he removed from Athens to Egypt, and succeeded Zenodotus in the office of librarian to the famous library at Alexandria. This office he retained under three successive princes, discharging his trust with singular honour, and acquiring high reputation for literature and science by his writings and discoveries. Availing himself of the multitude of historical memoirs, which the library furnished, he was both prompted and enabled to determine the dates of many distinct facts, by laying down certain chronological canons, for which see CHRONOLOGY. He also employed his eminent abilities and learning, with equal success, in reducing geography to a regular system, and laying its foundation upon clear and solid principles. He likewise first introduced into his map a regular parallel of latitude, which was a geographical outline traced over certain places, whose longest day was observed to be exactly of the same length. He began it from the straits of Gibraltar, and it thence passed through the Sicilian sea, and near the southern extremities of Peloponnesus, and was continued through the island of Rhodes and the bay of Issus, and then entering Cilicia, and so crossing the Euphrates and Tigris, was extended to the mountains of India. By means of this line he endeavoured to rectify the errors in the ancient geographical map, supposed to be that of Anaximander. In drawing this parallel, he was regulated by observing when the longest day consisted of  $14\frac{1}{2}$  hours, which Hipparchus afterwards determined to be the latitude of  $36^\circ$ . The running of this parallel through Rhodes was a happy thought of Eratosthenes, because it not only encouraged him to trace upon his map other parallels at certain intervals from his first, such as one through Alexandria, another through Syene, and another through Meroe, but he undertook to trace at right angles to these a meridian passing through Rhodes and Alexandria down to Syene and Meroe. His progression this way enlarged his ideas with regard to the sciences of geography and astronomy, and induced him to attempt a more arduous task, which was that of determining the circumference of the globe by an actual measurement of one of its great circles, making his computation upon the whole by uniting certain accurate observations made in the heavens with a corresponding distance carefully surveyed, and taken upon a meridian of the earth. The segment of the meridian which he fixed upon for this purpose, was that between Alexandria and Syene, the distance of which was measured, and found to be 5000 stadia, and the angle of the shadow upon the scaphia, or sun-dial, which was observed at Alexandria, was equal to the 50th part of the circle; for at Syene there was no shadow from the gnomon at the mid-day of the summer-solstice; and that this might be more accurately taken, they dug a deep well, which being perpendicular, was completely illuminated at the bottom, when the sun was vertical. The substance of this account was taken from Cleomedes, who seems to have extracted it from Eratosthenes's original work, entitled *Μέγεθος*. (See Fabr. Bell. Græc. vol. ii. p. 477.) And it is published as such at the end of the Oxford edition of Aratus in 1672, though under the title of *Μέγεθος τῆς γῆς περιφέρειας*. By this account Eratosthenes made the circumference of the earth amount only to 250,000 stadia, whereas a multitude of original authors, (such are Strabo, Geminus, Vitruvius; Macrobius, Pliny, Capella, and Censorinus,) have uniformly given the numbers to be 252,000. In order to reconcile these differences, Dr. Murdoch (Enquiries con-

cerning Measures of length, prefixed to Busching's Geography, vol. i.) has ingeniously supposed, that instead of  $7^\circ 12'$ , the difference of latitude was  $7^\circ 8\frac{1}{2}'$ , which was the  $\frac{1}{3}$  of the circumference, which would bring the calculation to 252,000 stadia, and that Cleomedes neglected the small fractional part of the denominator; but that the principal mistake was in measuring the distance, and finding it to be 5000 stadia. Eratosthenes, by making the circumference to be 250,000 stadia, allowed 700 stadia to a degree, which, by the reduction of 8 stadia to a Roman mile of 5000 feet, amounted to  $87\frac{1}{2}'$  Roman miles to each degree. We shall return from this digression, after observing, that the map of Eratosthenes appears to have contained little more than the states of Greece, and the dominions of the successors of Alexander, digested from preceding surveys. He had seen indeed, and has quoted the voyages of Pytheas into the great Atlantic ocean, which gave him some faint idea of the western parts of Europe; but they were so imperfect, that they could not be realized into the outline of a chart. Strabo tells us that he was extremely ignorant of Spain, Gaul, Germany, and Britain, as well as of the Gæti and Bastarni; he was equally ignorant of Italy, the coasts of the Adriatic, of Pontus, and of all the countries towards the north. And he mentions in another passage, that Eratosthenes had made the distance from Epidamnus, or Dyrrhachium, on the Adriatic, to the bay of Thermæ on the Ægean sea, quite across Epirus, to be only 900 stadia, when it was really above 2000 stadia; and in another instance he had enlarged the distance from Carthage to Alexandria to be 15,000 stadia, whereas it amounted to no more than 9000 stadia.

Eratosthenes also observed the obliquity of the ecliptic, which, in the year 230 B. C. he makes  $23^\circ 51' 20''$ . (See ECLIP TIC.) In an epistle to king Ptolemy he gave a solution of the problem for the duplication of the cube; and he invented a convenient method of discovering the primary numbers, that is, such as have no common measure but unity, which has been called the sieve of Eratosthenes. He wrote also numerous treatises in grammar, astronomy, history, and geography, together with dialogues on the philosophical sects, and poems. Fragments merely of his different pieces have reached our times, some of which were published at Oxford in 1672, with brief annotations, in 8vo. These fragments were also printed in the Uranologium of Petavius at Paris in 1630, and afterwards at Amsterdam in 1703. The most valuable remnant of his works is his "Catalogue of the kings of Thebes in Egypt, from Menes, who first peopled Egypt after the deluge, to the time of the Trojan war." This contains a series of 38 kings in a direct line of succession, taken not only from the records in the Alexandrian library, but from the sacred archives in Diospolis, or Thebes itself, and probably intended for supplying the defects, and correcting the errors of Manetho's dynasties. This has been used by some of our ablest chronologers as an authority for settling the Egyptian chronology. Eratosthenes died at the advanced age of 80 or 81, having, as some authors report, starved himself to death, because he was unable to bear the depression of spirits occasioned by the decay of his sight. Suidas. Voss. de Hist. Græc. Fab. Bib. Græc. Moren. Anc. Un. Hist. Gen. Biog.

ERBACH, in Geography, a small town of Germany, in the circle of Franconia, anciently called Erdtpach, with an old castle, belonging to the counts of Erbach, who, before the dissolution of the German empire, had two voices at the diet of Ratisbon, in the college of the imperial counts of Franconia. The whole county is about 25 miles in length, and 20 miles in breadth; its population does not exceed the

number of 30,000 individuals. It is a mountainous country, but tolerably fertile, and producing both corn and wine; of the latter, that of Schouberg, near the Bergstrasse, is reckoned the best.

ERBAT, a town of Asiatic Turkey, in the province of Diarbekir; 58 miles S.E. from Diarbek.

ERBAZ, a town of Asiatic Turkey, in the province of Natolia; 36 miles W.S.W. from Deguzlu.

ERBITA, in *Ancient Geography*, a town of Sicily, written Herbita by Cicero. It is thought to be the modern *Nicosia*.

ERBLSPACH, or ERLSBACH, in *Geography*, a town of Germany, in Lower Bavaria; 34 miles E.S.E. from Ingolstadt.

ERCABUM, in *Ancient Geography*, a town of European Sarmatia. Ptolemy.

ERCE, in *Geography*, a town of France, in the department of the Ille and Vilaine, and district of Bain; 15 miles E. from Bain.

ERCEUS, of *επος, septum*, in *Mythology*, the name by which those who were appointed to guard the walls of a city invoked Jupiter. This appellation, sometimes written *Herseus*, was given to Jupiter, because his altars, especially in the houses of princes, stood under the open air in places inclosed with walls.

ERCHEE, in *Geography*, a town of Persia, in the province of Adirbeitzan; 60 miles E.N.E. of Tauris.

ERCILLA Y ZUNIGA, DON ALONZO DE, in *Bio-geography*, an eminent Spanish poet, was born at Madrid in 1533. His father, descended from a noble family, pursued the profession of the law, but dying while Alonzo was an infant, the child and his mother were received into the household of Isabella, wife of Charles V. Alonzo, as soon as his years permitted, was made page to the infant don Philip, whom he attended in his progress through the Low Countries, and part of Germany and Italy. He afterwards accompanied the same prince to England, to celebrate his marriage with queen Mary. During their stay here intelligence was received of a revolt in Chili, upon which troops were immediately sent off, with whom Ercilla embarked and proceeded to Lima. His duty required him personally to engage in a subsequent war with the Araucanians, whose courage and love of liberty he admired, and even applauded, though he was under the necessity of using all his efforts in subduing them. The intervals of warfare he employed in recording, in heroic verse, the interesting scenes to which he was witness. After he had escaped the dangers of the expedition, he had nearly lost his life at a tournament exhibited in honour of the accession of Philip II. During the fête a dispute arose between Ercilla and another gentleman; swords were drawn, and many joined in the conflict, which being construed into a plan of mutiny by the governor, he hastily, and without examining into the matter, condemned the principal disputants to be beheaded. Ercilla was led to the scaffold, and his innocence was demonstrated but just in time to save him from an ignominious death. He returned to Spain with his health very much impaired, in his twenty-ninth year; but after a very short stay at home, he commenced a tour through various parts of Europe; but with what particular view has never been ascertained. In 1570 he married, and was made gentleman of the bed-chamber to the emperor Rodolph II. Ten years after this, he was found residing at Madrid, in retirement and poverty. The king whom he had served, and to whom he dedicated his poem "Araucana," made him no requital for his services, and little more is known of him, than the mention made by a contemporary of his being engaged, in 1596, in celebrating

the victories of the marquis of Santa Cruz, in a poem that has never been published.

The "Araucana" is an historical poem, containing a narrative of real events, interspersed with fabulous circumstances. It contains 37 cantos, is formed on no regular plan, but is an unconnected series of adventures. The verse is said to be flowing and spirited, though sometimes it is profane and insipid. Mr. Hayley, in his Essay on Epic Poetry, has taken pains to make Ercilla known to the English reader, by translations of select parts, and an analysis of the whole poem. Gen. Biog. Hayley on Epic Poetry.

ERCTA, in *Ancient Geography*, a mountain of Sicily, near mount Erix. Diod. Sic. Polybius.

ERCYNA, a river of Greece, in Eæotia, not far from the cave of Trophonius.

ERDENI-TCHAO, in *Geography*, a town of Chinese Tartary, in the country of the Eluths; 680 miles N.W. of Peking.

ERDER, a town of Germany, in the circle of Westphalia, and country of Lippe; 12 miles N.N.E. from Lemgow.

ERDMANSDORF, a town of Germany, in the circle of Upper Saxony, and circle of Erzgeburch; 5 miles E. of Chemnitz.

EREBENNUS, *ερεβενδος*, a name given by Galen and some other of the Greek writers, as a distinctive epithet for the black chamæleon thistle, which was esteemed poisonous, and was by this word distinguished from the ægleus, or *αργυρε*, or white chamæleon, which was an esculent plant, and used by some as an antidote. It has happened, however, that the white chamæleon thistle has been by some called a poison, as well as the black; but this is only owing to a mistake of Pliny, in supposing the effects of birdlime to have been attributed to this plant, because of its yielding a viscous, but safe gum, at its root. It was called by some *ixias chamæleon*. See IXIAS.

EREBINTHUS, in *Botany*, (*ερεβινθος*), an ancient Greek name for some kind of vetch or legume), was applied by Mitchel to a supposed new genus of his own, which is the *Galega virginiana* of Linnæus. The latter in his Sp. Pl. inaccurately quotes Mich. Gen. which should mean Micheli, and professor Martyn, under his *Galega*, sp. 4, has Mant. Gen. both which would be unintelligible without an explanation.

EREBUS, *ερεβος*, from *ערב*, night, in *Mythology*, a term denoting darkness. According to Hesiod, Chaos engendered Erebus and Night, from whose mixture was born æther and the day. Aristophanes, ridiculing some ancient system of theogony, in his comedy of the Birds, introduces one of his actors as saying, that in the beginning were the Chaos, the black Erebus, and the vast Tartarus; but as yet there was neither earth, nor air, nor heavens. Night, with her sable wings, laid the first egg in the womb of Erebus, whence sprung, after some time, beneficent love, adorned with golden wings. From the union of love with chaos, arose men and animals. This was also the name of part of the inferi among the ancients: they had a peculiar expiation for those who were detained in Erebus.

Erebus was properly the gloomy region, and distinguished both from Tartarus, the place of torment, and Elysium, the region of bliss: according to the account given of it by Virgil, it forms the third grand division of the invisible world beyond the Styx, and comprehends several particular districts, as the limbus infantum, or receptacle for infants; the limbus for those who have been put to death without cause; that for those who have destroyed themselves; the fields of mourning, full of dark groves and woods, inhabited by those

those who died for love; and beyond these, an open campaign country for departed warriors. *Æn.* lib. vi. p. 427. &c.

EREC, or ERECH, in *Ancient Geography*, a town of Chaldæa, which is mentioned in the book of Genesis (ch. x. v. 10), as one of the places in which Nimrod began to establish his kingdom. This was probably the Aracca, placed by Ptolemy in Susiana, on the river Tigris, below its confluence with the Euphrates. Ammianus calls it Arecha. From this city the Aræctæan fields, which abound with Naphta, and sometimes take fire; derive their name.

"Ardet Aræctæis aut unda per hospita campis."

Tibull.

EREC, a province of Asia, which extended on both sides along the common bed of the Tigris and Euphrates, from their junction to the sea.

ERECT FLOWERS, in *Botany*, are such as grow upright, without hanging or reclining the head. See FLOWER.

ERECT leaf, *erectum folium*. See LEAF.

ERECT, in *Fortification*. The defences of a face, in fortification, are said to be erect when the several works bear directly and regularly upon the approaches, in such manner as to tend uniformly towards the capital, from which they are drawn respectively. Thus, when the two bastions which defend a curtain are equal and similar, and the raveline, with all its dependencies, stands evenly upon the line, or capital, of that face, without obliquity, or curve, the whole of such defences are said to be erect. It will be readily understood, that in every regular fortification the whole of the defences will be of this description: and that in all irregular fortifications there will probably be a mixture of erect and of oblique defence. The latter is by no means to be considered a defect; since innumerable cases might occur in which the prolongation, or the curtailment of any particular part, such, for instance, as the face or flank of a bastion, might be indispensably necessary, either to make way for some natural advantage, or to prevent that kind of weakness which might otherwise be entailed by the proximity of some height, whence enfilading might be successfully practised. When, therefore, the two bastions are dissimilar, or when they are unequal, so as to render the flanked angle of either less distant on the capital, if a line of defence were to be drawn upon, and formed from, the two extremities of such unequal bastions, the raveline must either stand a little obliquely, or the bastions must be unequally protected by it. This kind of obliquity is extremely rare, and is often neglected where great accession of strength might otherwise, by its adoption, be given to weak parts: it is peculiarly appropriate to fortresses, of which only one or two faces are understood to be subject to approach.

ERECT *Vision*, in *Optics*. See VISION.

ERECT, *direct*, and *declining*, &c. *dials*, &c. See DIAL.

ERECTHEUS, in *Biography*, is reckoned the 6th king of Athens, from Cecrops its founder, and is supposed to have succeeded his father Pandion about the year 1397 B. C. Some have referred to this reign the arrival of Ceres in Attica, after the rape of her daughter Proserpine, who taught the cultivation of corn, about the year 1383 B. C. and the institution of the Eleusinian mysteries. Erectheus reigned 50 years, and was slain in a battle with the Eleu-  
sians.

ERECTHIA, in *Ancient Geography*, a municipal place of Greece, in Attica, belonging to the Egeid tribe, and deriving its name from king Erectheus. It was the native place of the orator Isocrates.

ERECTION, the act of raising or elevating a thing in a right line.

The erecting of a perpendicular on a line given, is a popular problem in geometry. See PERPENDICULAR.

The term erection is also used figuratively; as the erection of a marquise into a duchy; bishoprics can only be erected by the king.

ERECTION, in *Physiology*, is the change in the state of the male penis, by which that organ is rendered capable of entering the vagina of the female, for the purposes of sexual intercourse. See GENERATION.

ERECTOR, in *Anatomy*, a name given to two muscles supposed to possess the power of bringing the organs with which they are connected into an erect state. They are the erector penis of the male, and erector clitoridis of the female subject. See GENERATION.

ERECTUM, FOLIUM, in *Botany*. See LEAF.

ERECTUS, CAULIS, an upright stem. See CAULIS, n. 6.

EREGEM, in *Geography*, a town of Flanders; 10 miles S.W. of Bruges.

EREGMOS, from ερημα, *I break*, a word used by the ancients to express a bean decorticated and broken into small pieces, in order to be boiled in ptisans; and also applied indifferently to all the leguminous fruits broken in the same manner.

EREKLI, in *Geography*, a town of Asiatic Turkey, in the province of Caramania; 60 miles E. of Cogni.

EREMEGIKE, a town of Asia, in Thibet; 25 miles S. of Tourfan.

EREMIT. See HERMIT.

ERES, or ERIS, in *Geography*, a town of Persia, in the province of Schirvan, on the borders of Armenia; 80 miles S.W. of Derbend, and 120 S.E. of Teflis.

ERESIA, in *Botany*, a name given by Plumier to a new American genus, Nov. Gen. 8. t. 25, in honour of the Grecian botanist Theophrastus Eresius; but Linnæus, and all succeeding writers, have, with the greatest possible propriety, called the plant *Theophrasta*, which see.

ERESMA, in *Geography*, a river of Spain, which runs into the Duero, between Simancas and Tordefillas.

ERESÓS, in *Ancient Geography*, a town of the island of Lesbos, which was the native place of Theophrastus.

ERESUS, or EBUSUS, a town of the island of Ebusus, founded by a colony of Carthaginians. Its harbour was commodious, its walls very large, and its houses well built.

ERETENUS, a river of Italy, in Venetia, famous, according to Ælian, for its excellent eels, and supposed to be the present Retona.

ERETHISMUS, (from ερεθίζω, *to irritate*, or *excite*). Medical writers extend the general meaning of this term to every kind of irritation which has a tendency to weaken and destroy the vital powers.

In this article we intend to take particular notice of a dangerous affection of the constitution, well known among surgeons by the name of the *mercurial erethismus*.

Mr. Pearson acquaints us, that on his first succeeding to the situation of surgeon to the Lock hospital, he had occasion to remark, that almost every year one, and sometimes two instances of sudden death occurred among the patients of that charity. No cause could be assigned for these events, but the subjects were commonly observed to be men who had either nearly, or completely finished a course of mercury. Messrs. Bromfield and Williams, on being consulted by Mr. Pearson, concerning these extraordinary cases, confessed themselves ignorant of the cause, mode of prevention, and treatment, and explained, that they had never been able to detect any diseased appearances in the bodies of such persons as had died in this sudden and unexpected manner.

Mr.

Mr. Pearson at length ascertained, that these unfortunate accidents were to be ascribed to mercury acting as a poison on the system, quite unconnected with its operation as a remedy; and that its deleterious qualities were neither in proportion to the inflammation in the mouth, nor to the actual quantity of mercury absorbed into the constitution. The disordered state of the system, implied by the mercurial erethismus, comes on after a long employment of mercury, and tends to a fatal termination. According to Mr. Pearson, it is characterized by great depression of strength, a sense of anxiety about the præcordia, irregular action of the heart, frequent sighing, partial or universal trembling, a small, quick, and sometimes an intermitting pulse, occasional vomiting, a pale contracted countenance, a sense of coldness; but the tongue is seldom furred, and the vital and natural functions are not much disordered.

Mr. Pearson observes, that when these, or the greater part of these symptoms are present, a sudden and violent exertion of the animal power will sometimes prove fatal. Walking hastily across the ward; rising up suddenly in the bed to take food; or slightly struggling with some of the other patients, are circumstances noticed by the above gentleman as having commonly preceded the sudden death of such persons as have died of the mercurial erethismus.

In order to avert the perilous effects of this peculiar affection, Mr. Pearson states, that the employment of mercury is, at all events, to be discontinued, whatever may be the stage, extent, or violence of the venereal symptoms. Every consideration must yield to the great object of extricating the patient from a state of impending destruction; nor would a perseverance in the use of mercury, under these circumstances, be of any avail, in regard even to the syphilitic complaints.

The patient should be exposed to a dry, cool air, without being subjected to any more fatigue than can be avoided. Mr. Pearson contends, that sitting in a room with a window open is not sufficient, but that the patient should go into a field or garden, and live as much as possible in the open air, till the above symptoms have disappeared. This plan should be conjoined with a generous diet. In this way patients have often been sufficiently relieved in the short space of ten or fourteen days, to re-commence the employment of mercury, and to bear its exhibition effectually, without any bad consequences.

The gradual approach of the mercurial erethismus is commonly indicated (according to Mr. Pearson's account) by paleness of the countenance, a state of general inquietude, and frequent sighing: the respiration becomes quicker, sometimes accompanied with a sense of constriction across the chest; the pulse is small, frequent, and often intermitting, and there is a sense of fluttering about the præcordia. In this early stage the further progress of the mercurial erethismus may be frequently prevented by the exhibition of the camphor mixture with large doses of the volatile alkali, the employment of mercury being at the same time suspended. Also, when the stomach is not oppressed by sarsaparilla, this medicine is productive of infinite benefit to persons afflicted with the mercurial erethismus. See Pearson on the "Effects of various Articles of the *Materia Medica* in the cure of Lues Venerea," edit. 2. p. 155 to 159.

ERETRIA, in *Ancient Geography*, a town of Greece, in the Phthiotide, a country of Thessaly.

ERETRIA, a town of the island of Eubœa, situated on the sea-coast at some distance to the south-east of Chaleis, opposite to the mouth of the Oropus, which, on the continent, separates the limits of Bœotia from those of Attica. This town was probably built by the Athenians, as Strabo

says, before, but according to Herodotus, after the war of Troy. It was for a long time a considerable place, and remained in a flourishing state under the reign of Darius, son of Hytaspes. It was destroyed by the Persians in the war of Greece, but was afterwards rebuilt, became very rich, and subsisted in the time of Strabo. It was amply furnished with pictures, statues, and such ornaments. We cannot trace any remains, except a persuasion that it existed in a place called by the modern Greeks *Gravelinas*.

ERETRIA terra, *Eretrian earth*, in the *Materia Medica*, the name of a very peculiar kind of alkaline bole, dug in the Negropont, near the ancient Eretria, and once in great use as an astringent and a sudorific.

The ancient writers in medicine all mention the Eretrian earth, and Dioscorides and Galen describe two kinds of it, a grey and white. The grey is what is properly distinguished by this name, being an earth of a different kind from all the other boles. The white, though the ancients seem not to have observed it, yet was plainly, from their own descriptions, the same with the white bole armenic, though found in a different place. Hill's *Hist. of Foss.* p. 5.

The grey or genuine Eretrian earth is a fine and pure greyish white earth, moderately heavy, naturally of a smooth surface, of a friable texture, easily crumbling to pieces between the fingers, but not staining the skin in handling; it sticks firmly to the tongue, but melts to a butter-like substance in the mouth; it burns to a perfect snow-white, and effervesces violently with aqua-fortis. But what abundantly distinguishes it from all other earths is, that if a little be wetted, and drawn over a plate of brass or copper, so as to mark a line, the mark will in a little time appear blueish. This is recorded of it so early as in the writings of Dioscorides, and experiment proves it to be true. It seems plainly to be owing to an alkaline quality in the earth; this it plainly manifests by its fermenting so strongly with acids; and it is as well known that alkalines draw a blue tincture from copper.

The ancients all esteemed it a great medicine, and were particularly careful in their way of preparing it for use, by frequent washing. It is now unknown in the shops, but its highly alkaline quality, in which it is so much superior to all the earths in use, might make it worth the bringing into use again; and it may still be had in its old place, in almost any quantities.

ERETRIAC SCHOOL, in the *History of Philosophy*. See ELIAC SCHOOL.

ERETRUM, in *Ancient Geography*, a town of Italy, in the country of the Sabines, N. E. of Rome, and S. W. of Cures. Strabo precisely marks its situation, when he says that it was on the Via Salaris, and that the Via Nomentana terminated there. It was at a small distance from the Tiber, near the 18th mile stone, according to the tables of Antonine and Peutinger.

EREUATIS, a town of Asia Minor, in Lycia.

EREUM, a town in the island of Sardinia.

EREWASH-CANAL, in *Geography*, is the parliamentary name of an important line of canal navigation, which nearly divides the counties of Derby and Nottingham for about twelve miles, of which an account has been given under our article CANAL, to this it may be necessary to add, that by the act of the 20th George III. for Cromford canal, the tolls on this canal for all articles, except coals and coke, were lowered to one-half of those mentioned in the original act, it being provided that no supplies of water to the canal should be taken for the use of the Cromford canal, except at thirty feet below the summit level of this. Upon this canal the very important experiment was tried,

at Ilkerton common, of suffering the coal-owners to work their coal under the canal instead of paying large sums in order to have the same left, as the act had provided, and a great length has been thus excavated and the ground settled, with only a trifling and temporary inconvenience to the canal, in raising the banks: on the Nottingham canal the same was also successfully tried, even under the locks, on the recommendation of Mr. Thomas Walker; see *Nottingham canal*. A rail-way branch conducts from the head of this canal to Beggarlea and another to Old Brinsley collieries in Nottinghamshire; and another, constructed in 1808, to the new collieries in Cotmanbury-wood in Derbyshire.

EREZEË, a small town of France, in the department of the Sambre and Meuse, chief place of a canton in the district of Marche, with a population of 640 individuals. Its canton has a territorial extent of 272½ kilometres, 13 communes, and 4519 inhabitants.

ERFA, a town of the island of Corsica; 25 miles N.N.W. of Bastia.

ERFURT, or ERFORT, anciently called *Erpes*, or *Erpifurt*, a very old town of Germany, in Thuringia, on the river Gera, 60 miles N. by E. of Coburg. N. lat. 51° 6'. It appears to have been founded in the beginning of the fifth century. The emperor Lewis held a diet at Erfurt in the year 852. The emperor Henry I. did the same in 935, and Rudolph I. in 1289. The last diet of the empire held at Erfurt was that of the year 1566. Erfurt was not an immediate free imperial city, but it enjoyed several considerable lordships and immunities, first under the protection of the landgraves of Thuringia, then of the princes of Brunswick, and lastly, from the year 1483, of the electoral house of Saxony: but the archbishops of Mentz claiming the sovereignty over Erfurt, it was at last agreed, in 1667, that they should keep a governor in the city, on the express condition that the Protestant doctrine and worship should be respected. The professors' chairs of the university, which had been established in 1392, were allowed to be filled half with Roman Catholic and half with Protestant teachers. In 1754 an academy of sciences was founded, to which were subsequently added a botanical garden, an anatomical theatre, an astronomical observatory, a riding school, and a society of natural history. The best public libraries are those of the Jesuits, of the Scottish convent, and of the Lutheran ministry, which contained some valuable ancient manuscripts of the Hebrew bible.

The most remarkable public building at Erfurt is its cathedral church, which is reported to have been built in the year 752. Its celebrated great bell weighs 275 cwt. In more superstitious times, pilgrims used to flock to Erfurt from all parts of Germany on a particular day, to dance the *dance of Death* (*den Todtentantz*.)

At the peace of Luneville, in 1801, the city of Erfurt, its territory and dependencies, and all the rights of sovereignty possessed by the ecclesiastical elector of Mentz, or Mayence, were ceded to the king of Prussia, as part of the indemnities to which this monarch was entitled for his losses on the right shore of the Rhine. The population of Erfurt and its territory, together with the Eichsfeld, was, in 1802, reckoned at 121,200 individuals, and in the territory of Erfurt in particular, inclusive of the town, there were 3517 individuals to the German square mile. The city of Erfurt, without the garrison, contained 16,500 inhabitants.

But Prussia having declared war against France in 1806, Erfurt was one of the first towns which surrendered to the French after the unfortunate battle of Jena or Auerstädt, in October 1806. The fort of Peterberg, which protects the city, and which had always been considered as very

strong, did not even attempt a defence. At the peace of Tilsit, in 1807, Prussia was stripped of all the new acquisitions and old possessions beyond the Elbe; and Erfurt, by the conqueror's decree of the 18th of August, 1807, was to form part of the new kingdom of Westphalia. But the French emperor having had a conference with the emperor Alexander I. of Russia at Erfurt in the month of October, 1808, this city was again transferred, by way of compliment, to the Russian emperor's brother-in-law, the present duke of Saxe-Weimar, who is a member of the Confederation of the Rhine. There is at Erfurt a considerable manufacture of ribbands, which employs above 500 individuals.

ERGALIA, of *εργον, opus*, a word used by the *Alchemists*, to express that part of their treatises which explains the instruments employed in their operations.

ERGANE, in *Mythology*, the *Inventress*, an epithet of Minerva, because to her was ascribed the invention of several arts; since, besides that of the art of war, Lucian ascribes to her that of architecture; the art of spinning, of making cloth, tapestry, silk and woollen stuffs, is also ascribed to her by the ancients. She was also reckoned the first who taught man to plant and cultivate the olive. She is likewise honoured with the invention of chariots, and of the use of trumpets and the flute, &c.

ERGASIMA, a name given by Dioscorides and other of the ancients to a very foul and coarse kind of myrrh.

ERGASTERIUM, a word used by the writers in *Chemistry*, sometimes to express the whole laboratory, and sometimes that part of a furnace on which the bottom of the retort, copel, or crucible, is to rest in an operation.

ERGASTINÆ, *Εργαστιναι*, in *Antiquity*, a select number of virgins employed in weaving Minerva's peplos or robe, which was carried in procession at the Athenian festival Panathæna. See *PEPLOS*, and *PANATHANEA*.

ERGASTULUM, among the *Ancients*, a house of correction, or workhouse, where slaves, by the private authority of their masters, were confined, and kept at hard labour for some offence. It was likewise called *sophronisterium*.

ERGATIA, *Εργατια*, in *Antiquity*, a Laconian festival, in honour of Hercules.

ERGAVIA, in *Ancient Geography*, a town of Spain, in the Tarragonensis. Ptol.

ERGAICA, a town of Hither Spain, S. of Bilbilis. This appears to have been a considerable place when it was taken by Gracchus in his campaign. Several medals were struck here, which represented Augustus and Tiberius, with an ox upon the reverse.

ERGENE, in *Geography*, a river of European Turkey, which runs into the Mariza, near Demotica, in Romania.

ERGERS, a river of France, which runs into the Ill, about two miles east from Grispoltheim, in the department of the Lower Rhine.

ERGETIUM, in *Ancient Geography*, a town of Sicily. Ptol. and Steph. Byz.

ERGINUS, a river of Thrace, in the vicinity of the Athyras, which ran before Sarpedon.

ERGITIUM, a town of Italy, in that part of Magna Græcia called Apulia, situated on the Appian way, between Teanum N.W. and Sipontum S. E.

ERGOT, in the *Manege*, is a stub, like a piece of soft horn, about the bigness of a chestnut, placed behind and below the pastern joint, and commonly hidden under the tuft of the fetlock. To dis-ergot, or take it out, is to cleave it to the quick with an incision-knife, in order to pull up a bladder full of water that lies covered with the ergot. This operation is scarcely practised at Paris, but in Hol-

land is frequently performed upon all four legs, with intent to prevent watery sores and foul ulcers.

ERGOT, in *Agriculture*, is a vegetable disease which affects different sorts of grain, and other crops, shewing itself, according to the author of *Phytologia*, by the seeds growing out into large horns, having a black appearance without, as in sea-cale, rye, and in carex. It very often attacks the rye in France, and occasionally in this country in such seasons as are very moist; the grain in these cases becoming considerably elongated, being either straight or crooked, containing a black meal along with the white; and is asserted to have the appearance of being pierced or perforated by insects, which are believed by some to be the cause of the affection. It has frequently other different appellations, such as clavus, or the spur, and horn seed. No certain remedy or method of preventing it has, we believe, been yet discovered. See next article.

ERGOT, in *Medicine*, a term originally applied, as we have seen, to a peculiar disease of corn, especially of rye, from the resemblance of the grains thus affected, to the spur of a cock: and, by metonymy, used to denote a disease in the human body, occasioned by taking this diseased, or *ergoted* rye as food.

The earliest account of this disease of rye, and of its pernicious influence on the human body, with which we are acquainted, is contained in a letter from M. Dodart to the editor of the *Journal des Savans*, published in March, 1676. (See vol. iv. part ii. p. 79.) The facts were communicated a few years before by the physicians and surgeons of Sologne, in which district the disease had been very prevalent. The grains of rye, affected by the ergot, according to M. Dodart, are of a blackish colour externally, but white within, and when dry, they are harder and of a more compact substance than the natural grains, and have no bad taste. They are considerably longer than the other grains, some of them being fourteen or fifteen lines in length, and two in breadth; and seven or eight of them are sometimes seen in one ear. They are obviously not foreign substances engendered between the grains of rye, M. Dodart adds, but the true grains, surrounded with their proper coats, in which the place of the germ is discernible. These grains were called *ergots*, *spurs*, in Sologne; in Gastoins, where they also were known, they were termed *bled cornu*. In various other places this diseased rye has been called *secale cornutum*, or *corniculatum*, *secale luxurians*, *clavus secalinus*, *mater secalis*, or *mutterkorn*, (by the Germans), &c. It is stated by Tissot, on the authority of Haller, that the ergot affects rye only, or two or three other Alpine plants of the grass-kind. (See *Philos. Transact.* vol. lv. for 1765, p. 110. A minute description of the ergot was published by C. N. Langius in 1717, the substance of which may be found in the *Acta Eruditorum* for 1718, p. 309.)

The learned Tissot, in his letter to sir George Baker, just referred to, states that there are two other diseases which affect rye and wheat, and which have been confounded with each other, as well as with the ergot, or *secale cornutum*, viz. the *rubigo*, or mildew, and the *ustilago*, *bruſure*, or blight; the former being characterized by the appearance of a reddish yellow powder, of a glutinous nature, adhering to the stalk and head of the corn; and the latter by a blackness and degeneration of the corn. (See Fontana on this subject, and sir Jos. Banks on the diseases of corn.)

The ergot was particularly observed in rye in wet seasons, and more especially when a wet spring was succeeded by excessive heat. M. Dodart remarks that the bread, which was made of ergoted rye, did not differ from ordinary bread

in point of taste; that this rye was most particularly pernicious when new; but that its effects were not observed until it had been eaten for a considerable time. M. Noël affirms that it loses its deleterious qualities altogether after being kept a few months in sheaf. (See a letter in *Queſnay's Traité de la Gangrène, seche*, p. 407, Paris, 1749.) And writers in general agree in stating, that the disease, which the ergoted rye induces, is prevalent only at the conclusion of harvest, and ceases before the commencement of winter; and that it was chiefly observed among the poor, who were unable to procure wheaten bread in those seasons of humidity and scarcity. (See Muller in *Comment. Lipsiæ*, anno 1752, p. 634, &c.)

The symptoms of the ergot in the human body are described somewhat differently by different writers; but they coincide in representing a dry gangrene, and ultimately death, as the ordinary results of the disease. It commences with a lassitude and debility, but with little interruption to the functions in general. A degree of torpor in the lower extremities is then observed, accompanied, according to some of the writers, with a sense of prickling, and of the creeping of insects (*formicatio*) upon the skin; a slight degree of swelling, but without inflammation, ensues, often accompanied by the most excruciating pains, and with a sense of burning heat; soon succeeded by that of extreme cold; the skin of the feet and legs becomes shrivelled, and of a dark hue, as if dried in smoke, afterwards black and destitute of feeling; in fact the limb dies, or is gangrenous, but in a dry state, which has been compared to that of a mummy. By degrees the dead parts separate from the living, as if they had been destroyed by caustic. In this mutilated condition, deprived of one, sometimes of both legs, more rarely of the hands or arms, some individuals have survived for months, or even years.

Besides this spontaneous gangrene of the limbs, another species of disease has been ascribed to the use of *ergoted* rye by Hoffmann, Tissot, and some other writers; but with what justice or propriety may perhaps admit of a question. The disease alluded to was a febrile disease, said to be of a contagious and malignant nature, and to be accompanied and principally characterized by various spasmodic and convulsive symptoms, by which, or by a general epilepsy, the patients were frequently carried off. This disease is said to have been epidemic in Heflia, Westphalia, and other parts of Germany, at several different periods, in the 16th and 17th centuries; and a description of it by the professors of the university of Marburg, in the year 1597, is generally referred to, as the first complete account of the disease. But in that account, of which a translation is given by Gregorius Horstius, no allusion whatever is made to the ergot, or *secale cornutum*; bad bread is mentioned only among other sorts of crude and unwholesome aliment, to which the disease (occurring in a time of dearth) is there ascribed. The whole of what is said respecting the exciting causes of that epidemic is contained in the compass of these few lines. "*Causas hujus affectus quod attinet, ex ægrotantium relatione scire licet, quod externa causa communiter in alimento, ad nutriendum minus idoneo et improporcionado, consistat, dum pauperes rebus ad vitam necessariis destituti, panem impurum et male coctum longo tempore, in summâ famiâ urgentiâ, devorant, interdum etiam poma acerba et auſtera, fungosque et similia deglutientes, sese edulis crudis, immaturis, et astrigentibus ingurgitant, de quorum depravatâ concoctione cruditates obortæ, &c.*" (See Greg. Horit. *Opera*, vol. ii. lib. viii. obs. xxii.) A similar statement, respecting the origin of this epidemic, is given by Sennertus in his chapter, "*De febre Malignâ cum Spasmo*," probably

upon the authority of the Marburg professors. The disease he supposed to be excited by a malignant vapour or humour, vellicating the brain and nerves. "Malignus autem ille vapor et humor ortum habuit ex victu pravo, dum, ob annonæ caritatem, panem non bonum, fructus corruptioni obnoxius, fungos, et id genus alia, ad explendam famem, pauperes devorabant. Ex quo victu pravo vitiosos humores in corpore colligi necesse est, &c." (Sennert. de Febribus, lib. iv. cap. 16.) The disease, therefore, is obviously considered by the original writers as originating from defect of nutritious food, and the ergot is not in any way alluded to. The symptoms of this fever, which was called by the Germans *die kriebel, krankheit, oder ziehende feuche*, the convulsive pebtilence, are thus briefly enumerated by Hoffmann. "The disease in its commencement occupies the limbs and the extremities of the hands and feet, in which a sense of formication is felt. In some instances it begins with sickness and vomiting. Then follow violent spasmodic contractions of the fingers and toes, which at length also attack the knees, shoulders, elbows, and even the face, eyes, and lips, accompanied by an intolerable pain, and sometimes with a sense of extreme coldness, sometimes with that of a burning heat. These symptoms return at stated periods, and sometimes continue for several weeks. As the pains diminish, the patients fall into a state of drowsiness and torpor, often into an alienation of mind, and are affected with giddiness and deafness, the limbs remaining stiff, and destitute of the power of motion. In the extremities of the limbs large vesicles, filled with serum, often appear, and sometimes other tumours, which pass into a gangrenous condition, but by a very slow progress, by which ultimately even the bones have been gradually destroyed. A state of general convulsion, or epilepsy, occasionally supervenes, and proves fatal, especially in children." (Hoffmann. Med. Rat. vol. ii. par. ii. cap. 9. § xvi.) A more detailed account of the symptoms is given by Sennertus, loc. cit. Dr. Cullen has followed Linnæus and Vogel in denominating this disease *Raphania*; (See Amœn. Academ. vol. vi.) but questions whether it be the same disease as the *Necrosis ustilaginea*, by which term Sauvages has designated the ergot. (See Cullen. Nosol. Meth. gen. 52. Sauvage Nosol. Meth. class. x. gen. 39.) There is, in fact, much confusion in the accounts of authors upon this subject; and it seems probable that the true effects of the ergoted rye are to be found only in the dry gangrene, and not in the epidemic fevers, which have been ascribed to it.

It was long ago known that corrupted corn was poisonous to the animal body. Galen remarked, that the seeds of colium temulentum mixed with wheat, or the degenerated grain, called black wheat, would produce fever, head-ache, delirium, and gangrenous ulcers. (De Aliment. facultat. lib. i. cap. 37.) Most of the writers on the subject, from M. Dodart downwards, have stated, that the ergoted rye, when given to fowls, hogs, and other animals, as food, produces the same symptoms as in man, and destroys life. More lately the Abbé Tessier made a series of experiments upon this subject, and has given a minute description of the ergot in rye. He found that by feeding or cramming turkeys and other animals with this diseased rye, he could produce in all of them the dry gangrene and death. (See Memoires de la Soc. Roy. de Medecine for 1776, p. 303. Hist. de l'Acad. des Sciences for 1710. Acta Erudit. Lips. 170 et 1752. Saviard Obs. Chirurg. The Treatise of M. Tessier, &c.)

The dry gangrene occurs from other causes than the ergoted rye. An account of a whole family consisting of eight persons, who were seized and mutilated or destroyed

by gangrene of the lower extremities, preceded by pain and some swelling, at Wattisham in Suffolk, is given in the Philos. Trans. vol. liii. part ii. The state of the family, three months after the commencement of the disease, is thus represented: "1. Mary, the mother, æt. 40. The right foot off at the ankle; the left leg mortified, a mere bone, but not off. 2. Mary, æt. 15. One leg off below the knee; the other perfectly sphacelated; but not yet off. 3. Elizabeth, æt. 13. Both legs off below the knees. 4. Sarah, æt. 10. One foot off at the ankle. 5. Robert, æt. 8. Both legs off below the knee. 6. Edward, æt. 4. Both feet off at the ankles. 7. An infant, four months old, dead." The father also suffered slightly in the fingers. Although the symptoms were exactly those of the ergot, yet, in this case no rye was eaten, nor could any other circumstance in the diet or economy of the family be discovered, to which the gangrene could be attributed. See GANGRENE.

ERIACH, in *Antiquity*, the name of a recompense assigned by the Irish Brehon law, in case of murder, to the friends, or to the child or wife of him that was slain, as a kind of composition between the murderer and his persecutors.

ERIAMBO, in *Geography*, a river of Russia, which runs into the Oby; 30 miles above Obdorokoi.

ERIANTHUS, in *Botany*, from *εἶν*, wool, and *ἄνθος*, a flower, Michaux Fl. Boreali-Amer. v. 1. 54. A genus of grasses established by Michaux, in its character very near *Saccharum*, but more naturally allied to *Andropogon*, to which, if the character of that genus were reformed, Michaux himself suspects the present might be referred. *Andropogon* indeed seems to require a thorough investigation, and probably a division into more than two genera.

ERIBANUM, in *Ancient Geography*, a town of Italy, in Campania, upon the Vulturinus. Polybius.

ERIBŒA, a town of Macedonia, in the country of the Parthæans. Ptol.—Also, a mountain of Macedonia; in the same country.—Also, a town of Asia, in Bithynia.

ERIBOLUM, the port of Nicomedia, a town of Bithynia.

ERIC, king of Denmark, in *Biography*. There were several princes of this name, though but few of them have any claim to notice in this place. Eric the First was possessed of so many virtues that he was surnamed the "Good." A musician, celebrated for his great skill on the harp, asserted that he could deprive his hearers of their understanding by the powers of his instrument. Eric challenged him to the trial, and in the paroxysm of phrenzy into which the performer threw the monarch, he killed four of his guards. Grieved at what he had done, he made all the recompense he was able to the relations of the deceased, and to do penance for the bloody deed, he determined to undertake a pilgrimage to the Holy Land. His subjects remonstrated against his design, but he was not to be dissuaded from his purpose, set out on his journey, and died at the isle of Cyprus. This event took place in the year 1107.

ERIC X., king of Sweden and Norway, as well as of Denmark, the son of Wratislaus VII. duke of Pomerania, was declared successor to the crowns of Denmark and Norway in the year 1388, by his great aunt, queen Margaret; and when, in 1396, she annexed the crown of Sweden to her dominions, Eric was, by the treaty of the "Union of Calmar," declared successor to that also. This celebrated treaty consisted of three articles 1. "That the three kingdoms of Denmark, Sweden, and Norway, should thence forward have but one king, who should be chosen alternately by each of them, and approved in a general assembly. 2. That the monarch should divide his residence equally between the three

## E R I C.

three kingdoms, and appropriate the revenues of each to its particular exigencies. 3. That each kingdom should retain its own laws, customs, senate and privileges; and that the subjects of the one should not be elevated to offices of profit or power in another." These conditions seemed, at first sight, to have been dictated by wisdom, but they proved to be the source of wars that continued to rage during a whole century between the three kingdoms. On the death of the queen in 1412, Eric succeeded without opposition to the three united crowns. He had married the daughter of Henry IV. king of England, with whom he had a large portion, and thus might be regarded as one of the most potent kings of his time. Eric was soon involved in a war with the princes of Holstein, which for some time was carried on with doubtful success, but in 1424 the whole of South Jutland, including Sleswick and Gottorp, was adjudged to the Danish crown. This award, which was made by the emperor Sigismund, at Buda, determined Eric upon a pilgrimage to the Holy Land. During the expedition, he was made captive, and obliged to pay a large ransom for his liberty. His absence from home was attended with other evils. From his accession he had displeased the Swedes by refusing to call a general diet for the confirmation of their liberties, which excited much discontent, that at length broke out into open rebellion. In 1435 he met the Swedish diet at Stockholm, and agreed to a full redress of grievances. His promises, however, were of little avail to his people, who, after enduring much from his misconduct, deposed him in 1439, and chose, in his stead, his nephew Christopher of Bavaria. For ten years he made many attempts to regain his situation, but without success. After this he employed himself in compiling a history of Denmark from the public registers, comprizing the period from the commencement of the monarchy to 1288. He afterwards repaired to the isle of Rugen, where he died in 1459. Eric possessed quick natural parts, and was a lover of learning; but he was ambitious, despotic, irrefolute, and insincere, qualities which led him into many difficulties, and which rendered his reign truly disastrous. *Univer Hist.*

ERIC XIV., king of Sweden, son of Gustavus Vasa, ascended the throne of Sweden in 1560, at the age of twenty-seven, and was possessed of all the accomplishments proper to his elevated situation. He spoke the modern languages, danced gracefully, shewed animation in all his actions, and was eloquent and polite. But he suffered himself to be hurried away with gusts of passion, which sometimes obliterated every trace of reason, and rendered him furious. His father, who had witnessed these fits of rage, had once formed the design of excluding him from the throne, and of conferring the crown on his second son. For the same reason he refused to permit him to visit England to pay his court to the princess (afterwards queen) Elizabeth: but negotiated the business by means of his ambassador and second son John. Eric, however, almost immediately after his accession, determined to obtain an interview with Elizabeth, and set sail with a large fleet and splendid train, but the vessels being overtaken by a violent storm, were driven back upon his own coast, where he suffered shipwreck, and for a time relinquished his matrimonial project. He next sent proposals of marriage to Mary queen of Scotland, and almost before he could obtain any answer, solicited from the emperor the hand of the princess of Lorraine, daughter of Christian II. with whom he was enamoured by the description of some of his courtiers. He received a favourable answer, but in the mean time he had changed his mind in favour of Elizabeth. His political conduct was as capricious as his amours, and involved him in continual quarrels

with his neighbours, and a confederacy was formed against him by Muscovy, Poland, Denmark, and Lubeck. His brother John, who had married Catharine, daughter of the king of Poland, fell under his suspicion, and was driven to an open rupture. John was cited to Stockholm, to vindicate his conduct, and refusing to appear, an army was sent into Finland with orders to seize him and his wife, and to bring them to the capital. He was immediately thrown into prison, accompanied by his wife, who voluntarily chose to share in his sufferings. It is said that the king went frequently to the prison with the design of murdering his brother, but that on seeing him he felt his heart so moved with pity, as to prevent him from striking the fatal blow. Sometimes with tears in his eyes he would confess the sanguinary design which had prompted his visit, and added, "I know that the crown of Sweden is intended for you, and I request that, when you are in possession of it, you will pardon my errors." This circumstance strongly displays the violence of contending passions in the mind of Eric, and has been brought to prove his insanity.

The early years of his reign were spent in wars chiefly with Denmark, carried on with vigour on the part of Eric, though without any permanent advantage. Domestic troubles at length withdrew his attention from foreign wars, and his capricious conduct destroyed all respect for him in the breasts of his subjects. Disappointed in his matrimonial projects, he entertained a number of concubines, one of whom, a peasant's daughter, gained such an ascendancy over him that he married her. He was under the influence of his ministers and domestics of mean rank, who frequently excited his jealousies of the great families. He entertained a particular hatred of the Stures, an illustrious family, descended from the ancient regents. Eric had taken one of them into favour, though he had, on a former occasion, disgraced him, and made him contemptible in the eyes of the populace. He now sent him in the quality of ambassador to Stralsund, but he became once more the object of the king's abhorrence, who conceived that he was conspiring against his life and crown. The king took pains to convince the states that Sture carried on dangerous intrigues at Stralsund; and he suborned witnesses to accuse him of treasonable designs. An infamous favourite, named Peerfon, persuaded Eric to extirpate the whole family; sentence of death was accordingly pronounced against those unfortunate men, together with twenty-six nobles, who were the pretended accomplices of a conspiracy laid to their charge. A public trial was afterwards allowed them, in which the Stures were able to vindicate their cause so completely, and to prove their innocence so undeniably, that the king himself apologized to them for their detention and long imprisonment: nevertheless, in a very short time, he stabbed Nils Sture with his own hand. The unfortunate man drew the dagger from his breast, and presented it to the monarch, who, with the most savage barbarity, ordered his guards to accomplish that which he had failed to perform himself. The rest of the prisoners were also cruelly murdered at the same time. No sooner was this bloody scene over than Eric felt the pangs of a wounded conscience. He grew frantic, and, as if pursued by the avenging furies, fled into the woods, where he wandered for many days like a wild beast, refusing to take food or repose. On his return he endeavoured to compensate for his cruelty, by bestowing large sums upon the friends and relations of the victims; and by giving up Peerfon to the hands of justice, who was condemned but not executed. Being threatened by the king of Denmark, Eric set at liberty his brother John, to whom and to his other brother he proposed assigning lands

in Livonia, in lieu of those left them by their father Gustavus. Shortly after he formed a design of putting them to death, and of conciliating the friendship of the czar of Muscovy, by delivering him the wife of duke John, to whom that prince had paid his addresses before her marriage. His intentions were discovered in time to defeat the purpose, and the brothers began to raise forces in their own defence. Eric made a stand, and an accommodation was effected, but by the treaty he bound himself to give up Peerfon, his favourite, who, being put to the torture, confessed a plot contrived by himself and the king, of pillaging Stockholm, burning part of the ships in the harbour, and proceeding with the rest loaded with spoil to Narva. The dukes now felt themselves justified in breaking the treaty, and they obliged Eric to capitulate in the citadel. He was put under confinement, solemnly deposed by the states, and duke John elected in his stead. His children were declared incapable of succession, and himself was condemned to perpetual imprisonment. His keepers were appointed from among the relations of those whom he had cruelly massacred, and who did not fail to subject him to various insults and indignities, and not unfrequently to the evils of cold and hunger. After nine years imprisonment, he finished a wretched life in 1578, in consequence, it was supposed, of a dose of poison administered by order of his brother John, who dreaded the possibility of his being liberated, and again set upon the throne. Eric was not deficient in talents; and he possessed great personal bravery: under his conduct the Swedish troops repeatedly distinguished themselves in contending with and overcoming the Danish armies, and it has been thought that he would never have submitted to the hard conditions which Denmark at length imposed on his successor. (See JOHN.) Univer. Hist.

ERICA, in *Botany*, *ερινος* of Dioscorides, the same name, variously corrupted, being applied to the several species of this genus among the modern Greeks at present, according to Dr. Sibthorp. See *Prod. Fl. Græc.* 256, 257.—Heath or Ling.—*Linn. Gen.* 192. *Schreb.* 258. *Willd. Sp. Pl.* v. 2. 356. *Ait. Hort. Kew.* v. 2. 14. *Sm. Fl. Brit.* 417. *Mart. Mill. Dict.* v. 2. *Juss.* 160. *Gærtn. t.* 63. *Tourn. t.* 373. *Class and order, Obandria Monogynia. Nat. Ord. Bicornes, Linn. Erica, Juss.*

*Gen. Ch. Cal.* Perianth of four ovate-oblong, permanent, upright, often coloured leaves. *Cor.* of one petal, permanent, four-cleft, regular, with an ovate or cylindrical tube, more or less inflated. *Stam.* Filaments eight, capillary, equal, inserted into the receptacle; anthers cloven at the summit, opening by two pores, by which they laterally cohere while young. *Pist.* Germen superior, roundish; style thread-shaped, straight, longer than the stamens; stigma capitate, in four or eight lobes. *Peric.* Capsule roundish, smaller than the calyx, which covers it, of four cells and four valves. *Seeds* numerous, affixed to the columella.

*Ess. Ch.* Calyx of four leaves. Corolla four-cleft. Stamens inserted into the receptacle. Anthers with two pores. Capsule superior, of four cells. Seeds numerous.

*Obs.* Some species appear to have a double calyx, but the lowermost was by Linnæus latterly esteemed rather of the nature of bractæas. The shape of the corolla is extremely different in different species, its tube being in some globular, in others ovate, in others again cylindrical and much elongated; sometimes dilated at the orifice, sometimes contracted, in some instances curved. The anthers, either included within the tube or projecting beyond it, are in some simply cloven at the top, without any appendage at the base; in some this latter part bears a pair of bristles,

in others a pair of notched leaflets, termed a crest, which, as Mr. Salisbury remarks, originate rather from the filament than from the anther.

This extensive and most elegant genus is confined to Europe and the southern part of Africa, the country about the Cape of Good Hope being, of all others, most abundant in Heaths, whence the green-houses of Britain are continually supplied with new species or varieties, to the great profit of nurserymen, some of whom find it worth while to keep a collector resident there. No *Erica* is found in America, in New Holland, nor scarcely in the Torrid Zone. The habit of the whole genus is shrubby, very rarely arborescent, with small, opposite or whorled, usually narrow, leaves, and bracted stalked flowers, whose colours partake of all the most exquisite tints of red, purple, yellow or orange, occasionally variegated with green or white. Some are entirely white, but the anthers are commonly dark brown or purplish.

It is difficult to guess at the number of the real species of *Erica*. Willdenow has 137, some of which are duplicates. Our gardeners reckon about 300, many of which are merely varieties, but there are several others only known hitherto in a dried state, and probably not a few yet remain to be discovered in the wilds of southern Africa.

The greater part blossom with us in the spring, but many at various seasons. They are for the most part inodorous, though a few of them are delightfully fragrant. They commonly keep well in an herbarium, provided they are dried suddenly, so as not to throw off their leaves during the process.

Few good figures of this genus, except of the European kinds, are found in the older botanical works, but many appear to great advantage in the more recent works of Ventenat, Wendland, Curtis's Botanical Magazine continued by Dr. Sims, and especially in a folio publication by Mr. Andrews, entirely devoted to the subject, as well as an octavo one, equally useful, by the same artist. The most superb of all, however, are two thin fasciuli, published by Mr. Aiton, of coloured plates by Mr. Frederick Bauer, but unhappily without any descriptions or even specific characters.

In the scientific definition of the species of *Erica* much yet remains to be done. The labours even of Linnæus and Thunberg are very far from perfection. Mr. Salisbury, who has paid much attention to the subject, has given an arrangement of 246 species, according to their natural affinities, in the sixth volume of the Linnæan Society's Transactions, with often expressive, if not classical, specific characters, but with an unlicensed change, and frequent perversion, of names. This writer includes the Linnæan genus *Blaria*, like Thunberg, under his *Erica*, while he excludes *E. vulgaris* as a genus, by the name of *Galluna*, and separates a few species (which have an irregular calyx, and fleshy fruit, with three cells and three seeds) into another genus, named, from its large stigma, *Salaxis*. To him we are indebted for remarking that the corolla of *Erica* is permanent, which is not the case in *Andromeda* and *Meuziæsa*, and that the anthers are united laterally to each other by their pores before they discharge the pollen. He also considers all true *Erica* as having the partitions of the fruit originating from the centre of each valve.

Linnæus and his followers distribute the species of this genus into three principal sections by the structure of the anthers; first, anthers arislated or furnished with a pair of bristles at their base; secondly, anthers crested, as above described; thirdly, anthers simple, or destitute of any of those appendages. The latter are subdivided into such as have

## ERICA.

the anthers included within the corolla, and such as have them projecting beyond its border. All these sections are moreover separated into subordinate ones by the situation of the leaves, whether opposite, or in three, four, or more rows, or scattered, of which last *E. glutinosa* is perhaps the only example. All these characters, however combined, unfortunately prove but artificial, separating species naturally allied to or resembling each other; nor are some of them, derived from the crested anthers, or number of leaves, constant or invariable, even in the same species. Still, as no natural subdivisions have yet been suggested, we may be glad of artificial and imperfect ones in so vast a genus. Mr. Salisbury, though he disposes the species in order, according to what he conceives to be their natural affinity or resemblance, especially in the form and proportion of the corolla, has not attempted to define or characterize many subdivisions of the genus. As, however, it is very instructive to contemplate the species of such a genus in this light, and as this writer's is the only attempt of the kind, we shall give examples of each of his subdivisions in the order in which he places them. It is necessary to premise that these subdivisions are considered as having in general no peculiar connection, and that one or more species often come between two of them, almost equally distinct from both and from each other. Thus, in the very beginning, *E. scoparia*, (*E. coris folio quarta*; Clus. Hist. v. 1. 42. f. 3.)—and *E. spiculifolia*, (Sm. Fl. Græc. Sib. t. 353. Prod. v. 1. 257.); stand as distinct from each other, and from three species immediately following them, among which are *absinthoides* of Linnæus;—and *setacea*, Andrews, t. 62.—Next come *planifolia*, Linn. (Pluk. t. 347. f. 1.) and *oxycoccifolia* of Mr. Salisbury, agreeing in their ovate dilated leaves, in which they are very unlike their neighbours. Then again *strigosa*, Ait. Hort. Kew. v. 2. 17;—and *scifolia*, Salisb. (rather *scifolia*), a new species, each stand separate, as not immediately allied to any other.—We shall, in separate paragraphs, mention one or more species of Mr. Salisbury's subdivisions, noticing likewise the separate anomalous species, and introducing two or three new ones, to the best of our judgment, according to their several affinities. Many still unsettled remain in every collection.

After *scifolia* follows an assemblage of eight species. Among these is *E. pubescens*, Linn. Sp. Pl. ed. 2. 506, *pellida* of Mr. Salisbury, thus characterized by him.—Leaves three in a whorl. Anthers crested, included. Flowers terminal. Leaves linear. Sides of the calyx doubled back. Corolla two lines long, downy on both sides. Crests short.—Also *E. urceolaris*, Berg. Cap. 107. Ait. and Bau. Ic. t. 16. (*pentaphylla*, Linn.)

Then 13 species with little or no affinity to each other, among which are *arborescens* (*E. coris folio prima*; Clus. Hist. v. 1. 41.); and *Thunbergii*, Linn. Suppl. 220, Curt. Mag. t. 1214, a most beautiful species, conspicuous for its globose white tube and large deep-orange limb; very rare at present in the gardens.

Next appears a collection of eight; among which is *melanthera*; another of three, including *capitata* and *bruniades* (Andr. t. 61.); and a third of 18, amongst which are *sexfaria*, Ait. and Bau. Ic. t. 11, with *nigrita* of Linn. and Thunberg, so called from its conspicuous dark anthers, elegantly contrasted with the white corolla and calyx. This last Mr. Salisbury is pleased to denominate *volutiflora*. These three subdivisions he indicates as not so distinct or dissimilar as most.

The following section comprises five new species of Mr. Salisbury's, named by him *sabritii*, *dianthifolia*, *brevifolia*,

*chlamydisflora*, and *selaginifolia*. They have all crested included anthers, and terminal flowers.

His *pannosa*, with a woolly corolla, stands alone.

Then follow 15 species, mostly *Blarica* according to Linnæus, having but four stamens; see *BLÆRIA*. Nor can we much object to the union of these two genera, except that in so vast a tribe, we may be glad of even so slight a circumstance as number to make a genus, when there is moreover such a difference in habit as this very arrangement of Mr. Salisbury's implies. If indeed a few species of *Erica*, here and there in the different natural subdivisions, were tetrandrous, nobody would think of separating them for such a reason.

*E. nudiflora*, Linn. Mant. 2. 229. Sm. Plant. Ic. t. 57, (accompanied by two others) follows. Mr. Salisbury exults in having discovered its bractæas, which escaped Linnæus, Dryander, and the author of the present article, who in this instance readily submits to his correction. They are in the form of two or three excessively minute woolly scales, near the base of each flower-stalk.

The next five, or rather we would say seven, uniting two of Mr. Salisbury's sections, are *herbacea*, Linn. Sp. Pl. 501, Curt. Mag. t. 11, not at all different from *carnea*, Sp. Pl. 504; (this, according to Dr. Sibthorp, is the genuine *Erica* of Dioscorides, extremely common every where in Greece);—*mediterranea*, Linn. Mant. 2. 229, Curt. Mag. t. 471;—*multiflora*, Sp. Pl. 503, (Garidel. t. 32.), another beautiful native of the south of Europe, long confounded with *vagans*;—*manipuliflora*, Salisb. (Sm. Fl. Græc. Sibth. t. 352.);—*vagans*, Linn. Mant. 2. 230, (Engl. Bot. t. 3.) common on all the heaths of Cornwall, either with red, flesh-coloured, or white flowers;—*umbellata*, Linn. Sp. Pl. 501, (Ait. and Bau. Ic. t. 5.);—and lastly *nutans*, Wendland. Eric. fasc. 3. 5.—The native country of this last we know not, nor have we seen Wendland's publication. The rest of this very natural assemblage grow in Europe only.

*Filiformis* and *turgida*, Salisb. we have not ascertained to our satisfaction.

Nine species, very naturally allied, having excessively long anthers, projecting from an elongated tubular corolla, are placed next. Among these are *E. Plukenetii*; *Petiveri*; *Banksii*, Andr. t. 26; *Sebana*, Dryand. in Ait. and Bau. Ic. t. 10; &c. mostly familiar to collectors.

Nine more comprehend *imbricata*, Linn. Sp. Pl. 503;—and *flexuosa*, Andr. Eric. t. 33;—with *leucanthera*, Linn. Suppl. 223;—and *milleflora*, Berg. Cap. 96, which last name is well retained by Mr. Salisbury, in preference to the inaccurate one, *paniculata*, given by Linnæus.

An assemblage of six more contains the beautiful *baccans* Linn. Mant. 2. 233, Curt. Mag. t. 358, a good specimen of the rest.

Five following ones are supposed to be little, if at all, related. Among them are the beautiful *glauca*, Andr. t. 47, Curt. Mag. t. 580; in the same section with which the *elegans*, *ibid.* t. 966, should be inserted. The flowers of the latter are larger, and differently coloured, but they closely agree in structure with those of *glauca*.—*E. Monsonia*, Dryand. in Ait. and Bau. Ic. t. 7, (*E. Monsoniana*; Linn. Suppl. 2. 3.), one of the most magnificent of all, is placed by Mr. Salisbury, with a sign of incomplete affinity, after *glauca*.—*E. halicacaba*, Linn. Sp. Pl. 507, Ait. and Bau. Ic. t. 2, follows alone. Its corolla is of a pale uniform yellowish green.

Ten species, with a long tubular corolla and short included anthers, are needlessly, we think, divided into three parcels. These are mostly handsome flowers, very frequently to be seen in gardens. Among them are *versicolor*, Andr. t. 12, which

which comprehends as a variety his *costata*, t. 46;—*discolor* of the same author, t. 3;—*cruenta*, Ait. and Bau. Ic. t. 13;—*abietina*, Linn. Sp. Pl. 506, (*E. Pattersonia* of Andr. t. 7, and the gardeners), remarkable for its thick-set leaves and crowded golden blossoms, as well as its pulpy seed-vessel;—and *concinna*, Ait. Hort. Kew. v. 2. 23, mistaken by Andrews, t. 64, for *abietina*. For this last (*concinna*) Mr. Salisbury has, in our opinion with advantage, adopted the name *paludosa* from Hermann, which indicates its place of growth, and consequently its requisite treatment in a garden.

*E. pyramidalis*, Ait. Hort. Kew. v. 3. 491. Curt. Mag. t. 366, with two others unknown to us, constitute the next subdivision.

Then follow 12 fine plants, needlessly, we again presume, divided into two parcels. Among them are *tubiflora*; *curvisflora*; *conspicua*, Ait. Hort. Kew. v. 2. 22. Ait. and Bau. Ic. t. 12; and *sordida*, Andr. t. 56; with several often confounded with these, (for it is rather an indistinct and perhaps variable tribe,) all which contribute much to adorn our green-houses, and are in general easily cultivated.

*E. fascicularis*, Linn. Suppl. 219. Ait. and Bau. Ic. t. 6; and *E. Massoni*, Linn. Suppl. 221. Curt. Mag. t. 356; occupy a section by themselves. These are two of the most highly prized of the whole genus. The flowers of both are tipped with green.

The 12 next are, in general, scarcely less splendid, witness *pharetriformis*, Salisb. (exurgens, Andr. t. 13.);—*grandiflora*, Linn. Suppl. 223. Curt. Mag. t. 189;—and *longifolia*, remarkable for its tremulous leaves and the variation of colour in its flowers, instances of which are displayed in Andrews, t. 8, t. 20, and t. 33; likewise in Curt. Mag. t. 402. The deep scarlet is justly the most admired variety.—We cannot but think *pineae*, Andr. t. 57, must be a distinct species.

To these are nearly allied the next five, comprehending *sessiliflora*, Linn. Suppl. 222, (*spicata*, Thunb. Diff. 43. t. 4. Andr. t. 6);—*alveiflora*, Salisb. called in the gardens *gelida*, which name aptly expresses the cool aspect of its snow-white corolla tipped with pea-green, and surely ought to have been retained;—and *mammosa*, Linn. Mant. 2. 234. Andr. t. 58. (*abietina*, Schneev. Ic. t. 23.); of which a beautiful scarlet variety is most common with us, called *speciosa* in Schneevoght, t. 3, and *verticillata* by Andrews, t. 21.

Of Mr. Salisbury's *brachialis*, a solitary species, we have only seen a doubtful specimen.

Four species follow, among which are *E. Sparmanni*, Linn. Fil. Suppl. 219. Stockh. Transf. for 1778. t. 2; and the noble *cerinthoides*, Linn. Sp. Pl. 505. Curt. Mag. t. 220.

*E. cernua*, Montin Nov. Act. Upf. v. 2. 292. t. 9. f. 3. Linn. Suppl. 222, stands alone; as does Mr. Salisbury's *doliiformis*, (*mammosa*, Thunb. Diff. de Erica, ed. Salisb. 42. f. 21.)

*E. australis*, Linn. Mant. 231, not uncommon in gardens;—and *ciliaris*, Linn. Sp. Pl. 503. Curt. Mag. t. 484. follow next. These are both European species, and are immediately followed by two others, our elegant English *E. Tetralix*, Curt. Lond. fasc. 1. t. 21. Engl. Bot. t. 1014, (a name changed by Mr. Salisbury to *botuliformis*, sausage-shaped);—and his *multicaulis*, the *stricta* of Donn and Willdenow, native of Corfica.

Next comes by itself our common British *cinerea*, Curt. Lond. fasc. 1. t. 25. Engl. Bot. t. 1015, more happily, but without any necessity, altered to *mutabilis*.

*E. regerminans*, Linn. Mant. 2. 232, only known in the

Linnaean herbarium;—and *pulchella*, Andr. t. 56, occupy two separate sections.

A very distinct and natural assemblage of four species next occurs, in which are *empetrifolia*, Linn. Sp. Pl. 507, known by its oairy corolla;—and *malleolaris*, Salisb. (*empetrifolia*, Curt. Mag. t. 447.)

The four next seem scarcely to be separable from them, if we may judge by *viscaria*, Linn. Mant. 2. 321. Andr. t. 55, the only one of the four with which we are acquainted.

A difficult family of seven species, with a hoary habit, and small turgid downy flowers, is placed next, of which *tardiflora*, Salisb. (*pubescens*, Curt. Mag. t. 480.);—and *hirtiflora*, Curt. Mag. t. 481, are examples. Both are distinct from, though nearly allied to, the real *pubescens* of Bergius and Linnæus, as well as from his *parviflora*.

A somewhat similar tribe, but smooth, and with larger more bell-shaped flowers, contains ten species. Amongst them is *margaritacea*, Ait. Hort. Kew. v. 2. 20. Andr. t. 54, very pretty when laden with its pearly blossoms.

*E. Bergiana*, Linn. Mant. 2. 235, remarkable for its reflexed calyx, with two others, come next, and lead insensibly to the following section.

This comprehends *pilulifera*, Linn. Sp. Pl. 407;—*obliqua*, Thunb. Diff. 44. Ait. and Bau. Ic. t. 3;—and *phycodes*, Linn. Sp. Pl. 506. Curt. Mag. t. 443; with four more.

*E. cernua*, Andr. t. 48, stands alone, but between it and *phycodes* we would introduce a new species, communicated by Mr. G. Hibbert among the rest of his dried specimens of this genus from the Cape, and by Messrs. Lee and Kennedy from their garden, where it first blossomed in 1808. We would name it

*E. rosaria*. Leaves in four rows, obtuse, recurved, toothed. Anthers simple, included, with long pores. Corolla ovate, viscid. The leaves resemble those of *phycodes*, but are more distant and recurved. Flowers about the ends of the branches, on mostly axillary, long, viscid stalks, with two or three oblong, pellucid, concave bractæas towards their middle; the flowers droop a little, and are remarkable for their fragrant scent, resembling that of roses. The calyx-leaves are like the bractæas, and about one-third as long as the corolla, which is of a pale straw-colour, ovate, inflated, viscid, its segments obtuse, crenate, but little spreading. Stamens about the length of the calyx; their filaments purple at the summit, without any crest or appendages; anthers brown, oblong, with pores two-thirds of their length. Germen turbinate, furrowed, smooth; style twice as long as the stamens; stigma capitate, dark coloured.

*E. pulchella*, Salisb. a new species, stands alone, the author being unacquainted with its affinity to any other.

Two others, unknown to us, occupy a section with *glutinosa*, Berg. Cap. 98. Ait. and Bau. Ic. t. 17. (*Andromeda droseroides*, Linn. Mant. 2. 239.) This is a beautiful plant, with all the habit of an *Erica*, nor any thing but an occasional luxuriance of number in the parts of the flower to make it an *Andromeda*.

A very splendid and distinct assemblage follows, of six species, distinguishable by their large flowers, with a long tube, always contracted at its mouth, and more or less inflated below. The border is spreading and ornamental. Among these are *retorta*, Linn. Suppl. 220. Curt. Mag. t. 362, first found at the Cape by Masson, not by Thunberg;—*ampullacea*, Curt. Mag. t. 303;—and *Aitonias*, Curt. Mag. t. 429. This last varies a little in the size and hue of its border, but so strikingly resembles the Catalonian Jasmine, that we long ago named it *jasminea*, nor is there any occasion for the uncouth precision of *jasminiflora*.—We have still some of this tribe, which appear to be nondescripts.

Ten species with flowers of a somewhat similar form but smaller, and more slender needle-shaped leaves, constitute the next parcel. To this belongs *saffigata*, Linn. Mant. 66, of which there are several elegant varieties, named *E. Humea*, &c. in the gardens. Also *E. Muscari*, Andr. t. 1. smelling like the Musky Hyacinth, which it imitates in colour;—and *comosa*, Linn. Mant. 234, Ait. and Bau. Ic. t. 18.

A tribe more splendid in general, of nine species, succeeds. To these belong *inflata*, Thunb. Diff. 41. t. 2;—*ventricosa*, ibid. 27. t. 1. Curt. Mag. t. 350;—*lutea*, Linn. Mant. 234. Andr. t. 11;—*articulata*, Linn. Mant. 65. Curt. Mag. t. 423;—and *taxifolia*, Ait. and Bau. Ic. t. 19.

Two species, indicated as nearly related to the last, close Mr. Salisbury's list of 246 in all. These are *tetragona*, Thunb. Diff. 14. t. 4;—and *albena*, Linn. Mant. 231. Curt. Mag. t. 440.

We trust, that those who may have occasion to describe new heaths in future, will, as far as they are competent, keep the above arrangement in view, as they will find it very instructive, however they may differ from Mr. Salisbury in principles of nomenclature. To this subject we have scarcely found it necessary to advert, except occasionally, and we rather pass over in silence what we cannot approve. This botanist rejects all names of persons as applied to the species of any genus. Mr. Dryander once began a more useful reformation in such names of *Erica*, making those which commemorate a writer on the subject end in *ana*, as *Sebana*; those which apply to a collector only, in the genitive case, as *Maffoni*. The greatest and most correct information is still to be expected from this able botanist, in the intended new edition of Mr. Aiton's *Hortus Kewensis*, where the genus of *Erica* must always make a principal figure. S.

ERICA, in *Gardening*, comprehends plants of the ever-green, flowery, shrubby kind; mostly exotics; of which the species most in cultivation, according to Martyn, are: the cross-leaved heath (*E. tetralix*); the fine-leaved heath (*E. cinerea*); the double-anthered heath (*E. didyma*); the tree heath (*E. arborea*); the Spanish heath (*E. australis*); the many-flowered heath (*E. multiflora*); the Mediterranean heath (*E. Mediterranea*); the yellow heath (*E. lutea*); the purple-stalked heath (*E. halicacaba*); the bladder-flowered heath (*E. monfoncana*); the mucous heath (*E. mucosa*); the hairy-flowered heath (*E. urceolaris*); the marum-leaved heath (*E. maifolia*); the bloody-flowered heath (*E. cruenta*); the slender-branched heath (*E. rumen-tacea*); the blush-flowered heath (*E. perfoliata*); the three-flowered heath (*E. triflora*); the arbutus-flowered heath (*E. baccans*); the slender-twigg'd heath (*E. corifolia*); the crow berry-leaved heath (*E. nipetrifolia*); the woolly heath (*E. capitata*); the tube-flowered heath (*E. lubiflora*); the long-tubed yellow heath (*E. conspicua*); the honey-wort-flowered heath (*E. cerinthioides*); the tufted-flowered heath (*E. comosa*); the tall downy heath (*E. Maffoni*); the smooth-twigg'd pencil-flowered heath (*E. Plukenetii*); the downy twigg'd pencil-flowered heath (*E. Petiveri*); the early-flowered dwarf heath (*E. herbacea*); and the great flowered heath (*E. grandiflora*). But there are many other species equally deserving of cultivation.

Concerning the first of these species, it is observed by the editor of Miller's dictionary, that it is not inferior to many of the foreign heaths in the beauty and delicacy of its flowers. It is distinguished from the other British heaths not only by the flowers growing in a kind of pendulous cluster on the tops of the stalks, but by the leaves growing in fours, and forming a sort of cross.

The whole of the different species of heaths which are mentioned above, are plants of considerable beauty and elegance, but mostly tender and delicate in their habits of growth.

*Method of Culture.*—These very elegant plants must be treated in different methods, according to their nature and habits of growth.

The first three British sorts are capable of being propagated by sowing the seeds either in the places where they are to remain, or in pots filled with peaty earth, in either the autumn or spring seasons; but this is a tedious method of practice. The better method is, therefore, to take them up from the places where they grow naturally, in the early autumn, with good balls of earth about their roots, planting them again immediately where they are to grow and remain for ornament.

They are found to succeed best where the soil is of the peaty or moory kind, and where it has not been enriched by manure; and as they protrude their roots chiefly near the top, it should be as little dug about them as possible, the surface only being kept clean and free from rubbish.

And the four following sorts may be increased in the same manner as the above; but the best practice is by layers, cuttings, or slips, which should be laid down or planted out in pots filled with boggy earth either in the early spring or the latter end of summer, plunging them in a moderate hot-bed, and giving them proper shade and water. When they have taken full root, they should be carefully removed with balls of earth about them into separate pots, being replaced in the hot-bed till they become well established, when they will be capable of bearing the open air in mild weather when the season is suitable.

All the other species may be increased either by cuttings or layers, but most of them by the former. The cuttings should be made from the best young shoots, and be planted in the spring season in pots filled with a composition of light boggy and loamy earth, being placed in the hot-bed, and covered with bell-glasses, and duely shaded from the sun, slight waterings being given when necessary; the layers are best laid down in the autumn, being managed in the same way as the cuttings. When the plants have become perfectly rooted, they should be removed into separate pots filled with the same sort of mould, being then put in the dry stove or green-house, where some of them require to be constantly placed.

But the ninth, twentieth, and twenty-sixth species must be raised by layers, as they have not yet been increased by planting their cuttings in the manner directed above.

Where seeds are made use of in producing these plants, they should be sown in pots filled with the above sort of earth in the early spring, and plunged in the hot-bed of the stove. When the plants have acquired a few inches growth, they should be removed into single pots with a little earth about their roots, and be replunged in the hot-bed in the stove, being preserved in it, or the warmest part of the green-house, during the winter season, and whenever the weather is bad.

The first three sorts afford an agreeable variety in the borders and clumps, as they continue long in flower. The four following kinds are likewise hardy, and afford variety among other potted plants in the open air during the summer months.

All the other species are more tender, but produce as agreeable an effect among the stove and green-house collection, from the great beauty and continuance of the flowers in many of the sorts.

*ERICA marina, sea-heath*, a name given by many authors

to a very beautiful zoophyte of the fucus kind, called by Mr. Ray and some others the fucus ericae folio.

ERICA, in *Ichthyology*, a name given by Gaza and some others, as the interpretation of the chalcis of Aristotle, that is, as the name of the common herring.

ERICÆ, in *Botany*, the third natural order in the ninth class of the system of Jussieu, so named from the genus *Erica* which makes a part of it. This order consists of such dicotyledonous monopetalous plants as have perigynous stamens, and the following distinguishing characters. *Calyx* of one leaf, permanent, sometimes superior, more frequently inferior and deeply divided. *Corolla* of one petal, sometimes deeply divided, inserted either into the upper part of the calyx, more commonly into its lower part, or into a gland at its base; mostly withering and permanent. *Stamens* of a definite number, distinct, inserted into the same part, or rarely originating from the lower part of the corolla; anthers mostly with two horns at the base. *Germen* superior, or rarely inferior; style solitary; stigma generally simple. *Fruit* either superior or inferior, with many cells and many seeds, either pulpy, or more generally dry with many valves, fixed by their bases to the central axis, the partitions originating from the middle of each valve. *Seeds* generally minute. *Stem* shrubby, of a more or less elevation, or herbaceous. *Leaves* alternate, or opposite, or whorled.

This order is in a great measure analogous to the Linnæan *Bicornes*, exclusive of the *Rhododendra* of Jussieu, which differ from his *Erica* chiefly in having the partitions of the capsule formed of the inflexed margins of its valves, and not originating longitudinally from their centre. Ventenat retains the name of *Bicornes* for the *Erica*.

The *Erica* are divided by Jussieu into two sections, 1. *Germen* superior, consisting of *Cyrilla*, Linn. (which being of the same genus as *Itea*, and having the capsule of the *Rhododendra*, is to be removed thither); *Blaria*; *Erica*; *Andromeda*; *Arbutus*; *Clethra*; *Pyrola*; *Epigæa* (removed by Ventenat to *Rhododendra*); *Epacris* (omitted by Ventenat); *Gaultheria*; and *Brossæa* (likewise omitted by Ventenat, a very uncertain plant).

2. *Germen* wholly or partly inferior, *Argophyllum*, Forst. and Linn. fil.; *Mæsa*, Forst; and *Vaccinium*.

A third section contains two genera allied to *Erica*, or supposed to be so, *Empetrum* and *Hudsonia*.

ERICALE, from  $\epsilon\rho\sigma$ , the spring, and  $\kappa\alpha\lambda\lambda\eta$ , beautiful, a name given by Renealm in his Specimen Hist. Plant. 75. t. 68. to the *Gentiana verna*, a most elegant vernal plant. Linnæus erroneously prints it *Ericoila*.

ERICERUM, a name given by Aetius and other authors to a sort of collyrium, used in weaknesses of the eyes, in which the herb erica or heath was an ingredient.

ERICEYRA, in *Geography*, a town of Portugal, in the province of Estremadura, on the sea-coast; 20 miles N. W. of Lisbon.

ERICHTHONIUS, in *Astronomy*, a constellation, the same as Auriga.

ERICOILA, in *Botany*. See ERICALE.

ERICU, a name given in Rheede's Hortus Malabaricus, v. 2. 53. to the *Asclepias gigantea*. It is corrupted from the Sanscrit name *Roey*.

ERICUSA, in *Ancient Geography*, one of the seven Æolian islands, now *Alicuda*.

ERIDANUS, in *Astronomy*, a constellation of the southern hemisphere, in form of a river.

The stars in the constellation Eridanus, in Ptolemy's Catalogue, are 34; in Tycho's, 19; in the British Catalogue, 54. See CONSTELLATION.

ERIDANUS, in *Ancient Geography*, a river of Italy, in Cisalpine Gaul, now the Po, which see. Virgil describes it as the largest river of Italy, calling it the king of rivers:

“Fluviorum rex Eridanus.”

—Also, a small river of Greece, in Attica, which pursuing its course to the W. of Athens, united with the Ilissus below that city.—Also, a river of Celtica, near the Pyrenæes.

ERIE, FORT, in *Geography*, a strong fortification in the township of Bertie, Upper Canada, situated on the N. shore of lake Erie, at its eastern extremity, and the W. bank of Niagara river; 27 miles S. by E. from Niagara fort, 18 above the carrying place of the Falls of Niagara, and 45 from fort Chippeway. This is a small stockaded fort, somewhat similar to that at Chippeway; and adjoining it are extensive stores as at Chippeway, and about half a dozen miserable little dwellings. It has a barrack for troops and a block house; and a company of soldiers is quartered here for the purpose of transporting the public stores. The lake narrows here into the Detroit strait, which carries the waters over the great falls of Niagara. The new fort is projected on a small height in the rear of the present garrison. The harbour is capable of accommodating vessels of any size, which lie opposite to the fort, at the distance of about 100 yards from the shore, exposed to the violence of the westerly winds; but the anchorage is good, and they ride in perfect safety. The little fort, with the surrounding huts built on the rocky shore, the vessels lying off at anchor before it, the rich woods, the distant hills on the opposite side of the lake, and the vast lake itself, extending to the farthest part of the horizon, altogether form an interesting and beautiful scene. N. lat. 42° 53' 17". W. long. 78° 20' 30".

ERIE, Lake, called also *Eric*, *Erige*, or *Erike*, or the lake of the Cat, is a lake of the fourth magnitude in North America, through which runs the line between the United States and Upper Canada. Detroit river on the west brings the waters of the great lakes with which lake Erie has a communication on the north-west; and Niagara river on the east forms its communication with the waters of lake Ontario and the river St. Lawrence. It is situated between 41° and 43° N. lat. and between 78° 48' and 83° W. long. It is of an elliptical form, being about 300 miles in length, and about 90, at the widest part, in breadth. The depth of water in this lake is not more than 20 fathoms, and in calm weather vessels may securely ride at anchor in any part of it; but when stormy, the anchorage in an open part of the lake is not safe, the sands at the bottom not being firm, and the anchors being apt to lose their hold. At this time the water becomes turbid, by the washing up of the yellow sand from the bottom of the lake; but in calm weather it is clear, and of a deep greenish colour. The northern shore of the lake is very rocky, which is also the case with the shores of the islands, of which there are several clusters towards the western extremity of the lake; but along most parts of the southern shore there is a fine gravelly beach. The height of the land bordering the lake is very unequal; in some places long ranges of steep mountains rise from the very edge of the water; in others, the shores are so flat and so low, that when the lake is raised a little above its usual level, in consequence of a strong gale of wind setting in towards the shore, the country is deluged for miles. To the very great insularity of the height of the land on both sides of it, is attributed the frequency of storms on this lake; the coast, however, on both sides, is generally favourable for the passage of batteaux and canoes. A peninsula, called Longpoint, runs upwards of eighteen miles into

the lake, and being composed of sand, is convenient for hauling boats upon it, when the lake is too rough for sailing and rowing. Towards the south side, however, on both sides of the lake, it would be impossible to land, on account of the perpendicular height of the rocks. There is a great deficiency of good harbours along the shores of this lake: on its northern side there are but two places which afford shelter to vessels drawing more than seven feet water, *viz.* Long Point, and Point Abineau, and these afford only a partial shelter. On the southern shore, the first harbour you come to in going from fort Erie is that of Presqu'ete, which is situated at the distance from that fort of about six miles, and where vessels drawing eight feet water may ride in perfect safety. Beyond this, about midway between the eastern and western extremities of the lake, there is another harbour, capable of containing small vessels at the mouth of Cayahoga river, and another at the mouth of Sandusky river, which falls into the lake within the N. W. territory of the States. British ships seldom use these harbours, but trade almost solely between fort Erie and Detroit river, and in case of contrary winds, they return to fort Erie, if bound to Detroit river; or to some of the bays amidst the clusters of islands situated towards the western extremity of the lake, if bound to fort Erie. The navigation of this lake is very uncertain; and vessels are often detained, at a considerable expence to passengers, in some of the harbours. Lakes Huron and Michigan afford communication with lake Erie, by vessels of eight feet draught. There are portages into the waters of this lake from the Wabash, Great Miami, Muskingam, and Alleghany, from two to sixteen miles. The islands at the western end of the lake, of various sizes, lie very close to each other, and exhibit a very pleasing scenery; the largest of them are not more than fourteen miles in circumference, and many of them are very small. The largest islands produce a variety of fine timber, amongst which are found oaks, hickory trees, and red cedars, which latter, being large, are sent for even from the British settlements on Detroit river, at the distance of forty miles. Lake Erie has a great variety of fine fish, such as sturgeon, eel, white fish, trout, perch, &c. Amongst the woods are found racoons and squirrels, and also bears, in the winter season, when the lake is frozen between the main land and the islands. All the islands are dreadfully infested with serpents, and on some of them rattlesnakes are so numerous, that in the height of summer it is dangerous to land. Two kinds of rattlesnakes are found in this part of the country; the one is of a deep brown colour, clouded with yellow, about thirty inches in length, which frequents marshes and low meadows, and does great mischief among cattle: the other sort is of a greenish yellow colour, clouded with brown, and nearly twice the size of the former. Many different kinds of serpents, besides rattlesnakes, are found on the islands in lake Erie. The ponds and marshes in the interior parts of these islands abound with ducks and other wild fowl, and the shores swarm with gulls; among the woods are a few small birds, remarkable neither for their song nor plumage. *Weld's Travels, vol. ii.*

**ERIE**, a county of Pennsylvania, on the south side of lake Erie, containing 639,400 acres, and 1468 inhabitants. Its chief town is Erie.

**ERIEUX**, a river of France, which runs into the Rhone, at Beauchastal.

**ERIFFS**, a name given to canary birds when about two years old. See **CANARY BIRD**.

**ERIGENA**, **JOHN SCOTUS**, in *Biography*, who flourished in the ninth century, was probably born in Ayrshire Scot-

land, though some writers make him a native of Herefordshire, in England, and others suppose his birth-place to be Ireland. He possessed an ardent thirst for literature, and spared no pains in rendering himself accomplished in the learning of the East, and from the extent of his erudition he obtained the name of "Scotus the Wise." He studied some years at Athens, and became very conversant in Greek philosophy. Upon his return, he accepted an invitation from Charles the Bald of France, and lived for several years in habits of intimacy and familiarity with his royal patron, who assigned to him the direction of the university of Paris. To the sovereign he was not only an instructor in literature and science, but an adviser in the affairs of government. The high rank which he obtained excited much jealousy, particularly among the bigotted priests, who accused him of maintaining heretical opinions. In the year 824, the Greek emperor, Michael the Stammerer, sent to the Western emperor, Lewis the Pious, a copy of the treatises of the supposed Dionysius the Areopagite, which had long been held in great veneration among the Greek Christians. Dionysius was supposed to be the first Christian teacher in France, and, on that account, the work in question was deemed of great value, and the king, who was unable to read the original Greek, employed Erigena to translate it into the Latin language. Unfortunately this was performed without licence from the pope, who, when he found the translation eagerly read, insisted that the French king should not only banish Erigena from Paris, but should send him to Rome. Charles refused to act in this ungenerous manner, nevertheless, it was deemed advisable, that Erigena should leave the capital of France, and in a short time after he took refuge in England. This translation of Dionysius's treatises is said to have caused the revival of the knowledge of the Alexandrian Platonism in the West, and to have laid the foundation of the mystical system of theology which afterwards so generally prevailed. Of the original works of Erigena, the principal was his treatise "On the Division of Nature, or the Nature of Things," which was published from the author's MS. by Dr. Thomas Gale, at Oxford, in 1681, under the title of "Joannis Scoti Erigena de Divisione Naturæ, Libri quinque, diu desiderati." Erigena was employed by our great king Alfred in the restoration of learning at Oxford, where he was appointed professor of mathematics and astronomy. In this situation he remained only about three years, when some differences that took place in the university obliged him to retire to the abbey of Malmesbury in Wiltshire, where he opened a school. Here, it is asserted, by most writers, that he was murdered by his own scholars, either on account of his harshness and undue severity; or at the instigation of the monks, who hated Erigena as being a heretic, and much more learned than themselves. The particular time and place of his death have been the subjects of some dispute. Certain writers contend that his death took place about the year 864 or 865, and others, who are generally followed, make it in 883. Some say he died in England, and others, among whom is Dr. Henry, think that it happened in France. He was certainly a very extraordinary man for the times in which he lived, and after his decease his name was, for a considerable time, to be found in the list of the saints of the Romish church, till it was struck out of the calendar, on account of the heterodoxy of his opinions concerning transubstantiation. *Biog. Brit. Enfield's Hist. Phil.*

**ERIGENS PENIS**. See **ERECTOR**.

**ERIGERON**, in *Botany*,  $\epsilon\rho\iota\gamma\epsilon\rho\omega$  of the ancient Greeks, from  $\epsilon\rho\iota$ , the spring, and  $\gamma\epsilon\rho\omega$ , an old man, because it is hoary in the spring. *Linn. Gen. 422. Schreb. 553. Willd. Sp.*

Pl. v. 3, 1952. Sm. Fl. Brit. 876. Mart. Mill. Dict. v. 2. Juss. 180. Gærtn. t. 170. Class and order, *Syngenesia Polygamia-superflua*. Nat. Ord. *Compositæ discoideæ*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common calyx* oblong, cylindrical, imbricated; scales awl-shaped, erect, gradually longer, nearly equal in breadth. *Cor.* compound, radiated; *florets* of the disk all perfect, tubular, funnel-shaped, with an equal five-cleft limb; those of the radius female, ligulate, linear, awl-shaped, erect, for the most part entire. *Stam.* (in the tubular florets) Filaments five, capillary, very short; anthers forming a cylindrical tube. *Pist.* (in the tubular florets) Germen minute, crowned with hairs longer than its own corolla; style thread-shaped, the length of the hairs; stigmas two, oblong, revolute: the female or ligulate florets differ in having their corolla about as long as the hairs, and very slender stigmas. *Peric.* none, except the closed permanent calyx. *Seeds*, in the florets of the disk as well as of the radius oblong, small. *Down* long, capillary. *Recept.* naked, flat.

Obf. Dillenius observes that the innermost or central florets of the disk are generally males. One species has those of the radius destitute of a corolla.

Eff. Ch. Receptacle naked. Down simple. Florets of the radius linear, very narrow, numerous. Calyx imbricated.

This genus comprehends several plants called *Conyza*, *Virga-aurea*, *Aster*, and *Senecio* by former writers, but is a very natural one, characterized by the erect very narrow florets of its radius, usually coloured blue or white. The latest edition of Linnæus has 22 species, Willdenow 32. Three are natives of Britain.

1. *E. canadense*, Engl. Bot. t. 2019. "Stem hairy, panicled. Leaves lanceolate; the lower ones toothed."—To all appearance perfectly wild in Glamorganshire, (Mr. Middleton), though supposed by Ray to have come over from North America, where it abounds. It is an annual plant, of mean appearance, with innumerable small flowers, whose radius is white or pale red, their disk yellow.

2. *E. acre*. Engl. Bot. t. 1158. Curt. Lond. fasc. 1. t. 60. "Stem racemose. Stalks mostly single-flowered. Leaves lanceolate or tongue-shaped, sessile."—Common on a dry gravelly or chalky soil, flowering in July and August. The flowers are larger and fewer than in the former; their radius blue. Root biennial.

3. *E. alpinum*. Engl. Bot. t. 464. "Stems almost single-flowered. Calyx slightly hairy. Radius spreading."—Found in moist parts of the highland mountains of Scotland, flowering in July. This has seldom more than one flower on a stem, which is much larger than in *E. acre*, with a longish blue radius, which spreads more than is consistent with the generic character, and, perhaps, might authorize the removal of this species to *Aster*, where Linnæus originally placed it near ally *E. uniflorum*, Fl. Lapp. u. 307. t. 9. f. 3.

ERIGONUS; in *Ancient Geography*, a river of Macedonia, which, according to Livy, ran from Illyria through Pæonia into the Axios; called *Erigon* by Strabo and Ptolemy.

ERINACEA, in *Botany*, Tourn. Inst. 646, see ANTHYLLIS, sp. 15. Tournefort established it as a genus, (distinct from his *Genista-Spartium*, which consists of *Ulex* and the prickly *Genizæ*.) merely because the bush is all over armed with prominent strong spines, like a hedge-hog.

ERINACEUS, a name given by Dillenius and Micheli to a genus of *Fungi*. Linnæus, perceiving the inconvenience and absurdity of adopting a generic denomination, already

universally appropriated to an animal, changed it to *Hydnum*.

ERINACEUS, in *Zoology*, a genus of the *Feræ* order, the hedge-hog of English authors. This tribe is distinguished principally by the teeth. The fore-teeth in the upper jaw are two, and distant, in the lower two approximate; the tusks in the upper jaw five each side, in the lower three; grinders four each side above and beneath; body above covered with spines.

Species.

EUROPÆUS. Ears rounded; nostrils crested. Linn. Fn. Suec. *Erinaceus auriculis erectis*, Briff. *Echinus terrestris*, Geln. *Igel*, Knorr. *Herisson*, Buff. *Common hedge-hog*.

The common hedge-hog, or as it is sometimes called erroneously the European hedge-hog, appears to be a native of the temperate parts of Asia, and to be found in Madagascar as well as Europe. It lives in thickets and bushes, forming a nest of moss, grass, or leaves, of large size. When disturbed it rolls itself up into a globular form, presenting on every part a formidable armament of spines, and this is indeed its principal means of defence; upon being immersed in cold water it expands, and swims with perfect facility. During the winter it is supposed to remain in a state of torpidity.

Vegetables of various kinds, as the roots of plants, or fruits, reptiles, small birds and insects, constitute the principal food of this animal; the Calmucs tame and keep it in their dwellings like the cat; and in this respect they become useful, as they destroy the cockroaches, and other obnoxious insects. They produce from three to five young at a birth. The flesh is very indifferent, yet is spoken of among the old writers as an article of food, with instructions for roasting or otherwise preparing it for the table.

The hedge hog is considered as an inoffensive animal, notwithstanding the vulgar supposition, that it sucks the teats of cattle by night, and occasions ulcerations in those tender parts with the irritation of their prickles. The animal has a musky smell. Length ten inches.

INAURIS. Without external ears. Linn. Seba. *Gaiana hedge-hog*.

Length eight inches. Inhabits South America. The head is thick, short; spines cinereous tinged with yellow; hair soft, whitish chestnut over the eyes; tail short; claws long and crooked. Described on the authority of Seba.

AURITUS. Ears oval, long. *Auriculis ovalibus longis, naribus cristatus*, Pallas. Nov. C. Pet. *Siberian hedge-hog*.

Inhabits the lower parts of the Volga and Ural and extends from thence to the eastern parts beyond the lake Baikal. Its form resembles that of the common hedge-hog, but is smaller, the eyes larger, whiskers disposed in four rows; the feet longer, more slender; tail shorter, conic, annulated, and nearly bald. The female is said to breed twice a year, and to produce from four to seven each time.

MALACENSIS. Ears pendulous. Briff. *Hystrix brachyura*, Linn. *Porcus aculeatus*, f. *Hystrix malaccensis*, Seba. *Malacca hedge-hog*.

Extremely allied in its general appearance to the porcupine, and referred to the hedge-hog tribe chiefly on account of the number and arrangement of the teeth. Its size is supposed to be equal to that of the common porcupine. This animal is said to inhabit Asia, and to produce the precious stone called Piedra del Porco, the imaginary virtues of which are so highly extolled in the old materia medica.

SETOSUS. Ears shorter; top and hind head and shoulders beset with spines; tail very short and spinous. *Erina-*

*ceus fetosus*, Gmel. Schreber. *Tendrac*, Buff. *Petit tendrac de Madagascar*. Sonner. *Asiatic hedge-hog*.

Native of India and Madagascar; length six inches; wallows in the mire, and grunts like a hog, and forms burrows. Remains torpid for six months, during which the hair falls off.

**ECAUDATUS**. No tail; snout very long and acute. Schreber. *Tanrec, et le jeune tanrec*, Buff. *Madagascar hedge-hog*.

Inhabits India and Madagascar. In habit resembles the former, but is larger, measuring in length eight inches. The mouth and eyes are small; ears rounded and longer than in the fetosus; the spines black, and covering the whole back and sides; hair yellowish and feet tawny.

The two last mentioned animals are considered by Pennant as the same species, on the presumption that the former is the adult state, the other in a less advanced stage of growth. Dr. Shaw seems inclined to adopt this supposition. There, nevertheless, appears in our mind no plausible reason for such conjecture, unless the descriptions be defective in the most essential particular; for, if one has a tail and the other none, they must be distinct. That the animal described by Buffon had not obtained its full growth is rendered extremely probable by the explanation afforded, but the production of a tail cannot be supposed to depend on the age of the animal. The tanrec feeds on fruits, and remains torpid during about three months of the year.

**ERINÆI**, in *Ancient Geography*, a people of Asiatic Sarmatia. Ptolemy.

**ERINDES**, a river of Asia, towards Hyrcania or Sparta, according to Tacitus.

**ERINEUS**, one of the four cities of Doris, situate on the most northern verge of the kingdom, near the foot of the hills which part Doris from Macedonia.—Also, a port of the sea of the Peloponnesus, in Achaia, between Ægium and the promontory Rhium. Pliny.—Also, a river of Sicily, according to Thucydides, called *Orinos* by Ptolemy.

**ERINGO**. See **ERYNGO**.

**ERINNA**, in *Biography*, a Greek poetess, mentioned by different writers as a native of Lesbos, of Teios, of Rhodes, and of Tenos in Laconia, is supposed to have been contemporary with Sappho, about the year 600 B.C. but she is placed by the Chronicle of Eusebius 250 years later. She was celebrated in ancient Greece, and several epigrams were written upon her, one of which speaks of her as inferior to Sappho in lyrics, and superior in hexameters. Some fragments are extant in her name, which are inserted in the "Carmina Novem Poetarum Fœminarum." Antw. 1568. Voff. Poet. Græc.

**ERINUS**, in *Botany*, a name adopted by Linnæus from Dioscorides, the etymology of which is unknown. Neither is his *erinus*; the same with the Linnæan plant, but rather, we presume to think, something which has hitherto eluded the sagacity of commentators. His description accords in some points with *Samolus Valeranci*.—Linn. Gen. 3187. Schreb. 47. Willd. Sp. Pl. v. 3. 332. Mart. Mill. Dict. v. 2. Juss. 100. Gært. t. 55.—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Personate*, Linn. *Pediculares*, Juss.

Gen. Ch. *Cal.* Perianth in five deep, lanceolate, erect, nearly equal, permanent segments. *Cor.* of one petal, unequal; tube cylindrical, somewhat ovate, the length of the calyx, reflexed; limb flat, in five deep, nearly equal, inversely heart-shaped segments. *Stam.* Filaments four, very short, within the tube of the corolla; two of them (the uppermost) a little longer than the others; anthers small. *Pist.* Germen nearly ovate; style very short; stigma capitate. *Peric.* Capsule ovate, invested with the calyx, of two cells

and two valves, the latter cloven half way down when ripe; partition double. *Seeds* numerous, small. *Recept.* compressed.

Ess. Ch. Calyx of five leaves. Limb of the corolla in five, nearly equal, notched segments. Capsule of two cells. *Seeds* numerous.

Obs. By an unaccountable error in the Ess. Char. in all the editions of Linnæus the upper lip is said to be very short and reflexed, though the whole limb of the corolla is justly described as (nearly) equally five-cleft. Willdenow copies this, though the Hortus Kewensis had corrected it.

*E. alpinus* is the best-known species. "Flowers racemose. Leaves spatulate."—Linn. Sp. Pl. 878. Curt. Mag. t. 310. Native of the alps of Switzerland, and the Pyrenean mountains, flowering in the middle of summer. It forms tufts, with several dwarf stems, bearing numerous purple flowers, and is a very ornamental plant for rock-work, requiring protection against severe frost and excessive moisture, like most alpine rock plants. It is increased by parting the roots, or by seed.

*E. africanus*. "Flowers axillary, sessile. Leaves lanceolate, slightly toothed."—Linn. Sp. Pl. 878. (*Lychnidea villosa, foliis ex alis floriferis, &c.*; Burm. Afr. t. 50. f. 1.) Native of the Cape of Good Hope. This has a taller, more branched stem, more oblong leaves, and axillary flowers, of what colour we know not, with a very long slender curved tube. It has not yet appeared in our gardens.

*E. capensis*. "Flowers spiked. Leaves linear, toothed."—Linn. Mant. 252, excluding Burman's synonym. Gathered by Sparrmann in sandy ground at the Cape of Good Hope. This is also a stranger to our gardens. The flowers are said to be yellow and very fragrant. In the dried plant they are black. The tube is an inch and half long; the segments of the limb deeply cloven, the lobes dilated, obtuse and divaricated.

*E. fragrans*. "Leaves lanceolate-oblong, toothed. Segments of the limb undivided."—Ait. H. Kew. v. 2. 357. (Selago *Lychnidea*; Linn. Sp. Pl. 877. *Lychnidea villosa, foliis oblongis, &c.* Burm. Afr. t. 49. f. 4.) Native of the Cape, rarely seen in our green-houses. The flowers are yellow or brownish, and fragrant.

*E. trivilis*. "Leaves oblong, cut, toothed. Segments of the limb slightly cloven."—Linn. Suppl. 287.—Found by Thunberg at the Cape. The flowers are said to be sweet-scented, and of a dull colour.

*E. peruvianus* and *laciniatus* of Linnæus, are both nearly related to *Verbena Aubletia*, and the former at least seems to be the very same species.

**ERIOCALIA**, from *εριον*, wool, and *καλια*, a nest, in allusion to the singularly woolly involucre in the midst of which the flowers are seated as in a bird's nest. Sm. Exot. Bot. v. 2. 37. Intr. to Bot. 373. (*Aëtinotus*; Labillard. Nov. Holl. 67.) Class and order, *Pentandria Digynia*. Nat. Ord. *Umbellæ*.

Gen. Ch. *Umbel* simple, of many short rays. *Invol.* of many lanceolate, equal, undivided, coloured leaves, longer than the rays of the umbel, and densely clothed with wool. *Cal.* Perianth superior, in five deep, equal, concave, sometimes coloured, externally hairy, permanent leaves. *Cor.* none. *Stam.* Filaments five, about as long as the calyx, equal, awl-shaped; anthers roundish, of two lobes. *Pist.* Germen inferior, obovate, compressed, furrowed, very hairy; styles two, capillary, spreading, longer than the stamens; stigmas simple. *Peric.* Fruit ovate, obtuse, compressed, furrowed, hairy, crowned with the calyx and styles. *Seed* solitary?

Ess. Ch. Umbel simple. Involucre of many lanceolate,

late, equal, woolly, coloured leaves, longer than the umbel. Fruit compressed, hairy. Petals none. Many flowers abortive.

This New Holland genus bears the most striking analogy to the European *Afrantia*, from which it differs in its woolly, not smooth, involucre, but more essentially in having no petals, and in its hairy, not muricated, fruit. M. Labillardiere had, unknown to us, previously named it *Acinotus*, but that name being already long ago occupied in mineralogy, is untenable in botany.

The only species known are two.

1. *E. major*. Sm. Exot. Bot. v. 2. 37. t. 78. (*Acinotus helianthi*; Labill. Nov. Holl. 67. t. 92.) "Segments of the leaves bluntish, flat, woolly on both sides. Flower-stalks somewhat corymbose."—Native of the sandy country about Port Jackson, New South Wales, as well as of the west coast of New Holland, flowering in October. The root appears to be annual; it is woody and branching. Stem solitary, about two feet high, erect, leafy, round, woolly, but little branched except at the upper part, where the long flower-stalks, more or less numerous, grow in a corymbose form. Leaves alternate, stalked, three-cleft, lobed and pinnatifid; their segments spreading, linear, entire, flat, a little dilated upward, and bluntish; clothed with dense wool, whiter beneath. Stipules none. Flowers terminal, large and ornamental, all over white with a green or rufous tinge. Involucre of eight or ten spreading leaves, each an inch or more in length, peculiarly soft and pliable, like velvet. Flowers very numerous, forming a convex compact sort of disk, those of the circumference males. Calyx whitish, so as to resemble petals. No aromatic or pungent flavour is perceptible in any part of the plant.

2. *E. minor*. Sm. Exot. Bot. v. 2. 39. t. 79. "Segments of the leaves acute, revolute; smoothish above; silky beneath. Flower-stalks scattered."—Found near Port Jackson, in a sandy or gravelly soil, flowering in March.—Much smaller than the last, and bearing the same analogy to it that *Afrantia minor*, Sm. Exot. Bot. t. 77, does to the *major*, t. 76.—Root woody, branched, perhaps perennial. Stem a foot or two high, much branched, leafy, round, clothed with close-pressed hairs. Leaves on long foot-stalks, divided into three or five deep, spreading, dilated, acute, revolute, pinnatifid or three-cleft lobes; green, smooth, or slightly hairy, above; densely clothed with white silky hairs beneath. Flowers on long, solitary, terminal, naked stalks, scarcely a quarter so large as in the other. Calyx green, and not coloured. Involucre almost naked underneath; hairy, somewhat silky, white or reddish above. This species is likewise without any peculiar flavour.

ERIOCAULON, from *εριον*, wool, and *καυλος*, a stem, because of the woolly or hairy stalk, which however is rarely the case. Linn. Gen. 40. Schreb. 56. Willd. Sp. Pl. v. 1. 485. Sm. Fl. Brit. 1009. Juss. 44. Gærtn. t. 83.—Class and order, *Monoclea Triandria*, Smith. (*Triandria Trignia*, Linn.) Nat. Ord. *Junci*, Juss.

Gen. Ch. Common calyx globose, depressed, imbricated, many-flowered; its scales lanceolate or obovate, obtuse, scariose, equal, permanent; perianth inferior, of two or three obtuse, permanent, muricated leaves. Male flowers several, in the middle of the disk. Cor. funnel-shaped; tube about as long as the calyx; limb in two deep, obtuse, muricated lobes. Stam. Filaments three or four, equal, inserted into the tube of the corolla, and rather longer than the limb; anthers vertical, roundish, of two lobes. Pist. Germen obsolete; style capillary, cloven; stigmas blunt. Female flowers several, in the circumference, between the calyx-scales. Cor. inferior, of two oblong, concave, obtuse

petals, muricated at the upper part externally. Stam. none. Pist. Germen superior, of two or three lobes; style thread-shaped, shorter than the corolla, cloven; stigmas two or three, acute. Peric. Capsule roundish, of two or three lobes, with as many cells and valves. Seeds solitary.

Ess. Ch. Common calyx of many leaves, many-flowered; perianth superior, of two or three leaves. Male flowers central. Corolla of one petal, cloven. Female fl. in the margin. Corolla of two petals. Stigmas two or three. Capsule of two or three cells. Seeds solitary.

The characters of this genus were so ill defined in the works of Linnæus, that Hudson conceived our British *Eriocaulon*, confounded by Linnæus with his *decangulare*, must be a distinct genus, and he therefore called it *Nafmythia*, in honour of sir James Nafmyth, baronet; see Fl. Angl. ed. 2. 414. As however no genus can be more natural and distinct than *Eriocaulon*, and the fault appears to have been entirely in the descriptions of authors, its characters are now reformed. The above description is made from the only British species, *E. septangulare*, With. 184. Sm. Fl. Brit. 1010. Engl. Bot. t. 733.—"Stalk with seven angles. Leaves sharp-pointed, with an internal network of cells. Male flowers with four stamens." It grows in several lakes in the isle of Skye very abundantly, and was found in September 1801 by Dr. Wade, decorating the edges of all the lakes in Cunnamara, in the county of Galway, Ireland. The root is perennial, consisting of abundance of simple, white, shining fibres, composed internally of a series of cells, frequently interrupted by transverse partitions, which is the general structure of the whole herb. Stalk a span high, solitary, upright, simple, naked, twisted, with seven angles and as many intermediate furrows, smooth, (so that in this instance the generic name does not well apply), invested with a tubular sheath at the base. Leaves numerous, radical, sword-shaped, smooth, taper-pointed, about two inches long. Head of flowers terminal, solitary, hemispherical, about three lines broad, prettily variegated with dark purple and white, the calyx and anthers being of the former colour, as well as a few spots on the white corolla. The snow-white club-shaped protuberances, with which the extreme parts of the calyx and corolla are muricated, give the whole an elegant feathery aspect.

Linnæus knew about five species of *Eriocaulon*, but very imperfectly, and he was cautious of adopting Dr. Hope's accurate generic description of the above plant, published in the Philosophical Transactions, v. 59. 243. t. 12, lest it should not accord with every species. As far as subsequent examination of the several exotic ones has gone, it is found to confirm the account here given. Willdenow enumerates eight species in all; Lamarck describes 12 in his Encyclopædie, v. 3. 274—277, and figures 4, rather imperfectly, in his t. 50. This last author is, nevertheless, the best we have on the subject, though Willdenow hesitated to follow him, and Vahl, in his Sp. Pl. v. 2. 210, removes his *E. spadicum*, perhaps rightly enough, to *Schoenus*.

Authors are very much confused in their accounts of the native countries of several species. The *repens* of Lamarck was gathered by Thierry de Menonville in Hispaniola, not by Commerçon in the isle de Bourbon. *E. spadicum* of the same author was found by Smeathman at Sierra Leone, from whom we have it in plenty, and whom Lamarck rightly quotes; yet Vahl mentions St. Domingo (Hispaniola) as its native country, on the authority of Lamarck's herbarium, without naming Smeathman.

The following 6 species we believe are hitherto entirely non-descript. They will probably appear, with others, more fully illustrated hereafter from the pen of Mr. R.

Brown,

Brown, when he has time to resume the study of this genus, of which we believe he has ascertained about 30 species. In the mean while, to secure his specific names and our own thus far, we shall attempt definitions of what we have determined from actual observation.

*E. pygmaeum*, Soland. MSS.—Stalks aggregate, five-angled. Leaves and sheaths rough; the latter longest. Head globose. Calyx-scales obovate, pointed.—Native of New Holland. *Herb. Linn. fil.* The stalks are about two inches high. Leaves about half an inch long, being rather shorter than the sheaths of the stalks, which is unusual. Heads brownish.

*E. scariosum*.—Stalks aggregate, five-angled. Leaves and sheaths smooth, of equal length. Head globose. Calyx-scales obovate, acute.—Communicated from New South Wales in 1792, by John White, M. D.—Stalks five or six inches high. Heads of a silvery white, scarcely so large as a pea, being about twice as big as the former.

*E. flupeum*.—Stalk nearly solitary, five-angled. Leaves and sheaths of equal length, densely woolly at the base. Head hemispherical. Calyx-scales obovate, acute. Gathered by Sonnerat at the Isle de Bourbon. Stalk sometimes above a span high. Leaves spreading, involute when dry, smooth, or nearly so, but enveloped at their base, as well as the sheath of the stalk, by a dense integument of silky wool. Head much like that of *E. septangulare*.

*E. latifolium*.—Stalks somewhat aggregate, cylindrical, furrowed. Leaves smooth, taller than the stems. Head hemispherical. Outer calyx-scales rounded, obtuse; inner lanceolate, acute.—Gathered at Sierra Leone by Dr. Afzelius. The very long and broad flat leaves, a span in length, are remarkable. The sheaths are also large, about half as long as the stalk. Head smaller than in the last, variegated with brown and white.

*E. fistulosum*. Brown MSS.—Stalks aggregate, cylindrical, striated. Leaves smooth, twice as long as the sheaths. Head hemispherical. Inner calyx-scales obovate, pointed.—Native of New Holland.—Stalks a span high. Leaves about half as long, or more, taper-pointed, smooth, rather turgid. Heads small, brownish.

*E. depressum*. Brown MSS.—Stalks aggregate, cylindrical, furrowed. Leaves smooth, as tall as the stalks. Head flattened. Calyx-scales wedge-shaped, obtuse. Native of New Holland. Stalks about two inches high. Heads hemispherical beneath, nearly flat at the top, dark purplish brown.

We have in our descriptions substituted the word stalk (*scapus* or *pedunculus*) for stem, as being more correct. S.

**ERIOCEPHALUS**, so named by Dillenius from *εριον*, wool, and *κεφαλη*, the head, in allusion to the remarkably woolly appearance, singular in the tribe to which it belongs, which this plant makes when in seed. Linn. Gen. 450. Schreb. 586. Willd. Sp. Pl. v. 3. 2384. Mart. Mill. Dict. v. 2. Juss. 186. Gært. t. 168.—Class and order, *Syngenesia Polygamia-necessaria*. Nat. Ord. *Compositæ nucamentaceæ*, Linn. *Corymbifera*, Juss.

Gen. Ch. Common calyx erect, of ten ovate, equal, cohering scales; the five outermost keeled, the inner ones flat. Cor. compound, radiated; the perfect florets doubly numerous, constituting the disk; female ones five, making the radius: that of the perfect florets funnel-shaped, with a five-cleft spreading border; of the radius flat, inversely heart-shaped, with three terminal lobes. Stam. in the perfect florets, Filaments five, capillary, very short; anthers united into a cylindrical tube. Pist. in the perfect florets, Germen obsolete; style simple; stigma cloven, acute: in the female ones, Germen ovate, naked; style simple; stigma

pointed, inflexed. *Peric.* none, except the scarcely altered calyx. Seeds in the disk none; in the radius obovate, naked. Recept. flat, woolly, and the elongated wool which separates the two rows of calyx-scales, is moreover introduced between the perfect and female florets.

Obf. A small compressed body adheres to the base of each scale of the calyx.

Eff. Ch. Receptacle woolly. Seed-down none. Calyx of ten equal leaves. Florets of the radius five, inversely heart-shaped.

The species are two, both shrubs natives of the Cape of Good Hope, and to be met with, though rarely, in our green-houses.

1. *E. africanus*. Linn. Sp. Pl. 1310. Ait. Hort. Kew. v. 3. 278. Curt. Mag. t. 833. (*E. sempervirens, foliis fasciculatis & digitatis*; Dill. Elth. v. 1. 132. t. 110. f. 134). "Leaves lobed or undivided. Flowers corymbose."—The leaves are fasciculated, fleshy, and nearly cylindrical, hoary and glaucous, mostly undivided, sometimes with two or three lobes or notches. Flowers resembling many species of Yarrow, *Achillea*, having broad white radiant florets, and a small purple and yellow disk. The seeds are enveloped in the long soft hairs of the receptacle which come forth after the flowering is past. It is propagated by cuttings, and flowers from January to March.

2. *E. racemosus*. Linn. Sp. Pl. 1311. Ait. Hort. Kew. v. 3. 279.—"Leaves linear, flat, undivided. Flowers racemose."—The leaves are shorter, flatter, and less fasciculated than in the former. Flowers in long clusters or rather spikes. Wool of the receptacle very long.—Dr. Sims in Curt. Mag. justly refers Gærtner's synonym to the foregoing species, not to this.

**ERIOGONUM**, from *εριον*, wool, and *γονν*, a joint, in allusion to the woolliness of the habit, and the jointed structure of the stem. Michaux Fl. Boreali-Amer. v. 1. 246. Class and order, *Enneandria Trigynia*. Nat. Ord. *Holoraceæ*, Linn. *Polygonæ*, Juss.

Gen. Ch. Cal. Perianth inferior, in six deep, obovate, coloured, spreading segments, of which the three innermost are somewhat the largest. Cor. none. Stam. Filaments nine, occasionally eight or ten, rather longer than the calyx and inserted into its base, hairy in their lower part; anthers roundish, versatile, incumbent. Pist. Germen superior, oblong, triangular, with three furrows; styles three, the length of the stamens; stigmas simple, obtuse. *Peric.* Capsule triangular, membranous, not bursting. Seed solitary, triangular, sharp at each end, black; with a snow-white, small, farinaceous albumen, and large flat cotyledons.

Eff. Ch. Calyx inferior, coloured, in six deep segments, permanent. Capsule membranous. Seed solitary, triangular. Stigmas simple.

This genus in its parts of fructification very nearly approaches *Polygonum*, but the above characters are sufficient to distinguish it, and the habit, more especially the absence of stipulas, renders it totally distinct. We are possessed of three species, one of which only has been hitherto mentioned.

1. *E. tomentosum*. Michaux as above, t. 24. (*Chrysofenium? oppositifolium*; Walter Fl. Carolin. 140.) Calyx woolly, stem-leaves whorled, sessile.—We have been acquainted with this plant ever since November, 1793, when a root brought by Mr. John Frazer from Carolina, flowered for the first time in his garden at Chelsea. It was drawn by Mr. Sowerby, but the figure remains unpublished. Michaux in the mean while has named and described this genus as above, giving an indifferent plate of the only species known to him, which, he says, grows in the driest fir woods of Carolina

Carolina and Georgia, and which is the very same as Mr. Frazer's, in whose herbarium we have seen a specimen from Mr. Walter, who named it, with a mark of doubt, *Chryso-splenium oppositifolium*, not being furnished with sufficient materials to judge how far he was correct or not. Michaux has given a specific character, a perilous attempt, and indeed an absurd one, for a solitary species, as it can only by accident serve to contrast that species with others as yet unknown. The *Root* is perennial, rather woody, stem a foot or more in height, erect, round, woolly, rusty-coloured, leafy, branched and forked, many-flowered. *Leaves* nearly entire, somewhat undulated; green, scattered with loose, deciduous, rusty down above; densely woolly and whitish, with rusty veins, beneath: the *radical* ones clustered, obovate, two inches in length, on broadish woolly footstalks about half as long, spreading: *stem-leaves* in numerous rather distant whorls, three or four in a whorl, sessile, scarcely an inch long, unequal, pointed: *Stipulas* none. *Braheas* either terminal or from the forks of the stem, solitary, sessile, cup-shaped, bluntly toothed, woolly, containing eight, ten, or more inodorous flowers on simple, slender, woolly stalks, each joined in the middle, and swelling upwards. Segments of the *calyx* elliptical, broad, obtuse, white at the edge, green clothed with rusty wool at the back. The base of the *stamens*, and summit of the *flower-stalks*, are tinged with purple. *Fruit* covered by the closed internal segments of the *calyx*, become contracted at their base, and a little undulated.

2. *E. parvifolium*. Calyx naked. Stem-leaves stalked, alternate, ovate, revolute.—Gathered in California by Mr. Archibald Menzies. The *stem* is shrubby, branched, leafy, with a deciduous, nearly smooth bark. *Leaves* alternate or clustered, about a quarter of an inch long, ovate, obtuse, revolute, almost if not quite entire; smooth and shining above; densely clothed with rusty wool beneath. *Footstalks* half as long as the leaves, very woolly, dilated at their base, but not quite embracing the stem. *Flowers* very numerous, in dense, globular, woolly tufts, one terminating each branch, and surmounted by another, on an elongation of the same branch, two inches above it. *Flower-stalks* smooth. *Calyx* smooth, or very slightly downy at the back, its segments oblong, obtuse, keeled, entire, not wavy. We have not seen the radical leaves, nor been able to investigate the *braheas*. The round tufts of very copious flowers, and the stalked scattered small leaves, at once distinguish this species.

3. *E. latifolium*. Calyx naked. Stem-leaves stalked, alternate, heart-shaped, undulated. Foot-stalks embracing the stem.—Gathered in California by Mr. Menzies, with the last. *Stem* shrubby. *Branches* round, woolly, leafy. *Leaves* alternate, two inches long, heart-shaped, bluntish, undulated and crisped at the edge; covered with a web of deciduous white down above; very woolly and white beneath. *Footstalks* as long as the leaves, woolly, sheathing the stem with their dilated bases. Some leaves are clustered about the end of each branch. *Flowers* not larger than in *E. parvifolium*, and, as in that species, very numerous in globose woolly tufts, terminating elongated, naked, woolly branches. Segments of the *calyx* obovate, keeled, somewhat undulated.

The addition of these two species confirms the very natural genus of *Eriogonum*, which in the Linnæan system should immediately follow *Rheum*. Probably more species are to be found in the unexplored wilds of North America. Those we have described would all certainly bear the climate of Britain, and though not splendid plants, are worthy of cul-

tivation for their singularity. Their qualities cannot be supposed different from *Polygonum* and *Atraphaxis*. S.

ERIPHORUM, from *εριον*, wool, and *φορον*, to bear, alluding to the woolly or cottony tufts borne by the plant when in seed. Cotton-grass.—Linn. Gen. 30. Schreb. 41. Willd Sp. Pl. v. 1. 312. Sm. Fl. Brit. 58. Juss. 27. Gærtn. t. 2. Class and order, *Triandria Monogynia*. Nat. Ord. *Calamaria*, Linn. *Cyperoides*, Juss.

Gen. Ch. *Spike*, or rather *Catkin*, imbricated every way: scales ovate-oblong, flat, slightly inflexed, pointed, membranous, loose, separating the flowers. *Cor.* none. *Stam.* Filaments three, capillary, anthers erect, oblong. *Pist.* Germen superior, very small; style thread-shaped, the length of the calyx-scale; stigmas three, longer than the style, reflexed. *Peric.* none. *Seed* triangular, pointed, surrounded at the base with numerous hairs longer than the spike.

Ess. Ch. Glumes chaffy, imbricated every way. Corolla none. Seed one, invested with very long hairs.

Six species are described by Willdenow, four of which are found in Britain, viz. *E. vaginatum*, Engl. Bot. t. 873; *polystachion*, t. 563; *angustifolium*, t. 564, long confounded with the last; and *alpinum*, t. 311. The exotic species are, *E. virginicum*, Linn. Sp. Pl. 77; and *cyperinum*, *ibid*; both natives of North America. The latter has browner and shorter hairs to the seed than any other, so as to have nothing of their striking appearance. The whole genus grows in a turfy soil, generally in wet places, to which the first species is an occasional exception, being sometimes found on dry mountainous heaths. Some German botanists have lately distinguished from the *vaginatum*, one which they name *E. Scheuchzeri*. This is *Eriophorum*, n. 1332 β. Hall. Hist. v. 2. 175. (*Juncus alpinus*, capitulo tomentoso majori; Scheuchz. Prod. 27. t. 7. f. 2.) It has creeping roots, solitary stems, not half so tall, but much stouter than those of *vaginatum*, with a much less remarkable sheath. The leaves also are very short; the hairs of the seed very dense and remarkably delicate. It grows in the most elevated marshy pastures of the Alps, or about the boggy borders of Alpine lakes, as mentioned by Scheuchzer, and is undoubtedly a distinct species.

ERIPHORUS, BULBUS, the Woolly Bulb, *εριφορος* *επιφορος*; of Theophrastus, book vii. chap. 13, who mentions it as "growing on the shore, and having between its outer coats and the inner part, which is eatable, a woolly substance, of which various garments are woven." Pliny observes, that Theophrastus does not inform us in what country this is practised. Dodonæus, among the moderns first instituted an inquiry into this bulb, Hist. Stirp. 692, giving a figure, communicated by a friend of whose fidelity he is very unwilling to doubt, of a plant hitherto unseen by any other mortal. It has scaly bulbs, more resembling tuberous roots invested with the permanent bases of the foliage; long sword-shaped leaves: and large solitary flowers, unlike every thing known in the vegetable world, being formed of five densely shaggy ovate spreading petals, and a sixth standing upright in the place of the stamens and pistils. This cut has always been judged fictitious, and, if true, it would not answer to the description of Theophrastus. Dodonæus, moreover, figures the *Scilla hyacinthoides* as one kind of *Bulbus eriophorus*, and refers to Clusius, who, in his Hist. Plant. 173, gives *Scilla peruviana* for another. Both these bulbs, and, indeed, some others, have, in fact, a woolliness about their upper part when the coats are torn asunder, apparently consisting of their large and tenacious spiral-coated sap-vessels; but the quantity or quality of this wool is not, in any instance that has come under our inspection, by any means adequate to the uses mentioned in Theophrastus.

**ERIOSPERMUM**, from *επισπ*, wool, and *σπέρμα*, seed. Jacq. Coll. v. 5. 72. Willd. Sp. Pl. v. 2. 110. Class and order, *Hexandria Monogynia*. Nat. Ord. *Coronarie*, Linn. *Asphodeli*, Juss.

Gen. Ch. *Cal.* none. *Cor.* bell-shaped, permanent, of six ovate, equal, keeled petals, three of which are exterior and most expanded. *Stam.* Filaments six, shorter than the corolla, awl-shaped, uniform, dilated at the base, smooth; anthers incumbent, oval, two-lobed. *Pist.* Germen superior, ovate, with six ribs; style erect, angular, as long as the stamens; stigma simple, obtuse. *Peric.* Capsule of three cells and three valves; partitions from the centre of each valve. *Seeds* several, affixed to the lower part of each partition, roundish, invetted with long prominent woolly hairs.

Ess. Ch. Corolla of six petals, bell-shaped, permanent. Filaments broad at the base. Capsule of three cells. Seeds invetted with wool.

This genus, than which none can be more natural, either with respect to character or habit, was established by Jacquin in the fifth or supplemental volume of his *Collectanea*, upon the *Ornithogalum capense* of Linnæus and Thunberg, with two other species. They all agree in their tuberous root; radical, stalked, solitary, elliptic-oblong, entire, involute leaves; and tall, naked, racemose, many-flowered stalks. The flowers are small; petals white with reddish, brown, or greenish keels.—They are all delineated in Jacquin's *Icones Plant. Rarior.* v. 2, as follows.

1. *E. latifolium*, t. 420. (*Ornithogalum capense*; Linn. Sp. Pl. 441. Commel. Hort. v. 2. t. 88.) Leaves broadly elliptical, somewhat heart-shaped, recurved.—The leaves are of a dark shining green. *Partial flower-stalks* two inches long. *Petals* with a rose-coloured rib.

2. *E. lancifolium*, t. 421. Leaves ovate-lanceolate, acute, erect.—The upper side of the leaves is represented glaucous by Jacquin, their backs of a grass green. *Partial flower-stalks* but an inch long. *Petals* with a brownish rib.

3. *E. parvifolium*, t. 422. Leaves elliptical, obtuse, erect, flat. The leaves of this are glaucous, reticulated, and much smaller than in either of the former, being but from an inch and half to two inches long. *Petals* with a green rib. *Partial-stalks* an inch long, spreading.

All these species are natives of the Cape of Good Hope. We suspect that Bengal and the coast of Guinea may afford one or two more, but we are not furnished with materials sufficient to ascertain them completely.

**ERIOSTEMON**, from *επισπ*, wool, and *στέμον*, a stamen, alluding to the fringed filaments. Sm. *Transf. of Linn. Soc.* v. 4. 221. Class and order, *Decandria Monogynia*. Nat. Ord. *Rutaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, in five deep segments, nearly equal, permanent. *Cor.* Petals five, ovate, sessile, regular and equal, somewhat spreading, mostly five times as long as the calyx, sometimes rough, inserted under a glandular nectary, which surrounds the base of the germen. *Stam.* Filaments 10, awl-shaped, flattened, clothed or fringed with fine spreading hairs; anthers on terminal stalks, roundish with a small point, two-lobed, incumbent, smooth. *Pist.* Germen of five lobes, superior, standing on the nectary, each lobe somewhat ovate, triangular, acute, soon spreading; style central, from the base of the germen, erect, cylindrical, elongated after flowering, smooth; stigma capitate, with five notches. *Peric.* Capsules five, connected by their base, ovate, compressed, coriaceous, of two valves, enclosing an elastic, cartilaginous, bivalve arillus. *Seeds* solitary, kidney-shaped, brown, smooth.

Ess. Ch. Calyx in five deep segments. Petals five, sessile.

Vol. XIII.

Stamens flat, fringed. Anthers stalked, terminal. Style from the base of the germen. Capsules five, combined, seated on a glandular nectary. Seeds enclosed in an arillus.

Obs. Some species have a four-cleft flower, with but eight stamens, and others have five of their 10 stamens imperfect and abortive.—This genus differs from *Boronia*, Sm. *Tracts on Nat. Hist.* 287. t. 4—7, in having the anthers upon terminal footstalks, and the style from the base of the germen; not to mention the flowers being generally five-cleft and decandrous, and the leaves usually alternate. From *Correa* and *Crovea*, see vol. 10, its differences are evident from the characters there given of those genera. We are happy here to mention that the long-desired *Correa rubra* flowered, for the first time in Europe, at Messrs. Lee and Kennedy's, Hammermith, in June 1809.

The species of *Eriostemon* in our possession are six.

1. *E. salicifolia*. Willow-leaved Eriostemon.—Leaves linear-lanceolate, flat, straight, naked on both sides. Branches smooth. Flowers lateral. Gathered near Port Jackson, New South Wales, by John White, M.D. who communicated dried specimens to us in 1791, but it has not yet appeared in the gardens. This is a very handsome flowering shrub, with numerous, alternate, wand-like, leafy, smooth, angular branches, having indeed much of the habit of *Crovea saligna*. *Leaves* alternate, from one to two inches long, but little spreading, linear-lanceolate, entire, bluntish with a small point, thick and coriaceous, naked and smooth on both sides, besprinkled with glandular dots, scarcely veiny, but marked with an obsolete central rib; their base tapering down into a short flat footstalk. *Stipulas* none. *Flowers* pink, resembling those of *Crovea saligna*, on short, simple, solitary, axillary, angular, downy, bracteated stalks. *Bractees* imbricated, roundish, obtuse, concave, pale, downy, fringed. Segments of the calyx much resembling the bractees, about a line long, imbricated at their base. *Petals* alternate with them, and five or six times as long, obovate, spreading, bluntish, clothed with short, dense, scurvy pubescence, especially on the outside. *Filaments* about one-third as long as the corolla, red, all clothed from the base with dense, white, spreading hairs, and terminated by a naked, club-shaped, obtuse, red stalk, which in the five innermost alternate ones is much longer, thicker, and more glandular, than in the rest, rendering those stamens conspicuously the longest; anthers at the top of each stalk, incumbent, uniform, all fertile, ovate, of two cells, bursting longitudinally on their inner side, tipped with a small, pale, reflexed scale or crest. *Style* shorter than the stamens.

2. *E. luxifolia*. Box-leaved Eriostemon.—Leaves elliptical, keeled, revolute, with a recurved point. Branches hairy, round. Flowers lateral.—Gathered near Port Jackson, by Dr. White. Of this we have two very distinct varieties, for considering the Proteus-like nature of the leaves in New Holland plants, in which alone these differ, we dare not call them distinct species. In one the leaves are obovate, narrow at the base, bluntly crenate and glandular at the edges; in the other they are broadly elliptical, heart-shaped, and embracing the stem at their base, generally even and entire at their edges, though occasionally furnished, in the very same manner, with blunt glandular teeth. In both the branches are round, clothed with short prominent hairs. *Leaves* numerous, scattered, scarcely half an inch long, coriaceous, nearly smooth, keeled, with a sharp recurved point, and a thick, slightly revolute, margin. *Flowers* towards the ends of the branches, axillary, solitary. *Stalks* rather shorter than the leaves, thickened upwards, slightly

## ERIOSTEMON.

slightly hairy, with several minute, crowded, roundish, smooth *bracteas* a little above their base. *Calyx* much resembling the *bracteas*. *Petals* whitish or rose-coloured, almost as large as in the former, but smooth or very slightly downy; more spreading and recurved. *Filaments* minutely fringed, their terminal stalks awl-shaped, bearing a few long scattered hairs; anthers much like the former but shorter, and with a shorter broader point. *Germen* smooth, with very pointed lobes; style shorter than the stamens.

3. *E. falsifolia*. Salt-wort-leaved Eriostemon.—Leaves crowded, linear, obtuse; flattened above; convex beneath; rough-edged, straight. Flowers terminal.—Gathered by Dr. White near Port Jackson, with the last. It seems a more humble shrub than either of the foregoing, and has angular *branches*, all over scarred where former leaves have stood; slightly hairy when very young. *Leaves* very numerous, somewhat imbricated, half an inch or less in length, fleshy, linear inclining to obovate, obtuse, flattish above, convex beneath, more or less rough-edged, and sometimes otherwise pubescent, dotted with scattered glandular points, which in the dried leaves are prominent tubercles. The base tapers down into a very short broad *footstalk*, articulated with a decurrent prominence of the branch. *Flowers* few, terminal at the top of each branch, on short, simple, smooth stalks, which are minutely bracteated at their base. Segments of the *calyx* short, broad and acute. *Petals* recurved, downy, pale red with a darker keel. *Filaments* smooth at the base, their upper part, and terminal stalks, densely clothed with long, upright, white hairs, almost concealing the anthers, which are oblong, with a very minute point or crest. *Germen* smooth, with obtuse lobes.—The stamens in these three species would afford beautiful specific differences, were not those of the leaves more commodious and obvious.

4. *E. uniflora*. Single-flowered Eriostemon.—Leaves scattered, elliptic-lanceolate, smooth; paler beneath. Flowers solitary, terminal, on short stalks. Five of the stamens abortive. (*Diosma uniflora*; Linn. Sp. Pl. 287. Ait. Hort. Kew. v. 1. 276. Mart. Mill. Dict. v. 2. n. 17. Curt. Mag. t. 273. Schrad. Sert. Hannov. 16. t. 8.)—Native of the Cape of Good Hope, from whence it was sent to the Kew garden, in 1775, by Mr. F. Masson, and is now not unfrequent in collections, being much esteemed for its beautiful flowers, produced abundantly in the spring and early part of summer. This is a shrub from one to two feet high, much branched, strongly, but not agreeably, aromatic in all its parts. *Branches* leafy, nearly smooth. *Leaves* scattered, on short, rather hairy, *footstalks*, elliptic-oblong, often nearly linear, obtuse, very glandular, paler beneath, very obscurely crenate, and somewhat fringed, varying in length from half an inch to an inch. *Flowers* solitary at the end of each branch, but from the number of the short branches they sometimes appear cymose. *Stalks* much shorter than the leaves, swelling upwards, downy, without *bracteas*. Segments of the *calyx* near half an inch long, lanceolate, purplish, fringed. *Petals* twice as long as the *calyx*, obovate, pointed, of a shining varnished white, like porcelain, or often bluish-coloured above; purplish beneath. *Stamens* about the length of the *calyx*, their filaments all fringed; five of them short, bearing large heart-shaped anthers, with greenish glandular tips; five much longer and more slender, each terminating in a small round stalked gland, without any anther, varying in size and shape. *Germen* globular, clothed with numerous stalked nectariferous glands; style and stigma like the other species. Curtis and Schrader have well described this plant, but neither of them was sufficiently acquainted with the real species of *Diosma*, now nu-

merous in our gardens, to discover that it was generically distinct, and that the curious nectary, essential to *Diosma*, was wanting. Schrader endeavours to make his description of that part agree with the generic character, but in vain, and his accuracy would soon have discovered the truth, had he seen a real *Diosma*. The *Hankaea* of Schmidt in Uster's Annals, fasc. 6. 117, to which Schrader refers, agrees in generic characters with *Diosma barbiger* of Linnæus, and not with our *Eriostemon*.

5. *E. marginata*. Bordered Eriostemon.—Leaves scattered, lanceolate, paler beneath. Flower-stalks axillary, twice as long as the leaves, corymbose. Five of the stamens abortive. (*Diosma marginata*; Linn. Suppl. 155.) Native of the Cape of Good Hope, raised by Messrs. Lee and Kennedy, with whom it flowered in June 1809. It agrees very much in habit with the last, but has a more pleasant smell, like sassafras or myrrh, when rubbed, and differs very essentially in the great length of its *flower-stalks*, which are not terminal, but spring from the bosom of several of the uppermost leaves, and rising above the summit of the branch, make a sort of corymbus. A pair of lanceolate *bracteas* grow either near the top of each stalk, or towards its middle, or in our garden specimens, near the base. Their precise situation seems not characteristic of any specific difference. The segments of the *calyx* vary in breadth, and are often fringed, sometimes smooth. *Petals* mostly notched at the extremity, but otherwise like those of *E. uniflora*, as are also the *stamens*. The *leaves* vary greatly in length and breadth. Their membranous margin, whence the name is taken, is often very conspicuous in the dried plant, but we cannot perceive it in the living one, nor even in our garden specimens when dried, still we would not presume to change a name founded in truth, though not always applicable; otherwise *pedunculata* would be a more eligible one. Our remarks on this species are made from various specimens named and unnamed in the Linnæan herbarium, which vary greatly in the hairiness or smoothness of their branches and leaves, as well as the form and breadth of the *calyx*, but we can find no positive specific distinction among them. The leaves in some are nearly opposite, but never constantly so. We know, from frequent observation, that the last species is extremely variable, and are persuaded that this is subject to equal differences. The inflorescence, however, of each is so constant, that they can never be confounded together.

6. *E. paradoxa*. Various-leaved Eriostemon.—Leaves lanceolate, revolute, downy beneath; simple, ternate, or pinnate. Flowers lateral, four-cleft. Stamens eight. Sent from Port Jackson, New South Wales, by Dr. White.—*Stem* shrubby, with numerous, opposite, round, rough, leafy *branches*. *Leaves* an inch, more or less, in length, lanceolate, obtuse, entire, somewhat revolute; smooth and naked above; clothed with dense, white, entangled or starry pubescence beneath. In one variety they are simple, almost perfectly opposite, on short *footstalks*; in another smaller, ternate, sessile on one common winged stalk, which is about half the length of the lateral pair; in a third they are as large as in the first, and are either ternate or consist of two pair and an odd one, all sessile on a similar, but longer, winged stalk. The pinnate and the ternate kinds are unquestionably but varieties of each other, nor can we think the first a distinct species, however paradoxical our opinion may seem. The *flowers* of all are exactly alike. *Flower-stalks* copious, axillary, solitary, shorter than the leaves, simple, single-flowered, angular, clothed with rusty starry scales or pubescence. *Bracteas* two, towards the middle of each stalk, obovate, rusty, small. *Calyx* downy and rusty, quadrangular

quadrangular at the base, its four segments ovate, broad, keeled. *Petals* four, thrice as long as the calyx, elliptical, keeled, rose-coloured, smoothish above, downy beneath. *Filaments* eight, all nearly equal, rather shorter than the calyx, red, thick, obtuse, glandular, fringed in their lower part; anthers short and roundish, each on a short, slender, white, terminal stalk, their white tip or crest very minute. *Germen* reddish, with four blunt lobes.—We have hesitated whether to refer this plant to *Boronia*, with which genus it agrees best in habit, and number of parts in the fructification, but the insertion of the anthers and of the style have always appeared to us rather like *Eriostemon*. We have never seen it alive. Future observations on the living plant may correct our present determination. It appears to be one of the prettiest shrubs that New South Wales affords, and would be a welcome acquisition for the English conservatories. S.

ERIOX, or ΕΡΙΟΞ, in *Ichthyology*, a species of Salmo, called by Pennant, Willughby, and Ray the *Grey*. See SALMO.

ERISANA, in *Ancient Geography*, a town of Spain, in Lusitania.

ERISKAY, in *Geography*, one of the western islands of Scotland, separated from South Vist by a narrow strait, called "Eriskey Sound;" about five miles in circumference.

ERISMA, in *Botany*, according to the author of the name, is derived from *επιιδω*, to prop, or support, and not from *ερισ*, to dispute, or contend. Rudge Pl. Guian. 7. Class and order, *Monandria Monogynia*. Nat. Ord. uncertain.

Gen. Ch. *Cal.* Perianth of one leaf, permanent, downy on both sides, in four deep unequal segments, one of which is much the longest, irregular, obtuse, behind the larger petal; the rest sharper, and half-lanceolate. *Cor.* Petals two, opposite, unequal, emarginate, the uppermost united with the calyx betwixt its lesser segments, broad, roundish; its base ending in a horn-like, blunt *nectary*, the length of the petal, downy externally, like the calyx; the lowermost thrice as long as the other, and broader, inserted into the receptacle behind the perfect filament. *Stam.* Filaments five; one of them fertile, as long as the upper petal, incurved, inserted into the receptacle; the other four very short, abortive; anther arrow-shaped, narrow. *Pist.* *Germen* inferior, oblong, of one cell; style thread-shaped, as long as the filament, ascending; stigma blunt. *Peric.* unknown. Rudiments of seeds two, oblong.

Ess. Ch. Calyx in four deep unequal segments. Petals two, unequal; the uppermost united with the calyx, spurred at its base; the lowermost inserted into the receptacle. Fruit with two seeds.

*E. floribunda*. Rudge t. 1. Native of Guiana. A tree or shrub with round branches, when young clothed with starry down of a brown colour. *Leaves* large, nearly opposite, elliptical or obovate, obtusely pointed, entire, smooth, with numerous parallel veins. *Stipular* small, deciduous. *Panicles* large, terminal. *Bractees* in pairs, very unequal, downy, the smallest about a line long, the other four lines long, broad and ovate. The flowers are very small, and concealed by the bractees. Of their colour or properties we have no account.

ERISMATOLITHUS, in *Natural History*, and *Mineralogy*, is the name of a genus in the animal order of remains (*reliquia*, or relics) of a former race of beings, which inhabited the earth or its waters, and includes the *fulciments* or plant-like supports which certain animals fabricated for their support and habitation, and which are preserved in a fossil state. According to Mr. William Martin (*Outlines of the Knowledge of extraneous Fossils*, p. 193.) the essential characters or diagnostics of the permanent species in this

genus are to be sought in various parts of the *reliquium*, e. g. "In reliquia of cellular fulciments, the stirp exhibiting the internal form or structure of the cells: in reliquia of solid fulciments, the stirp exhibiting its external form." The temporary species of this genus are to comprise such cellular fulciments as do not shew the structure of their cells, and such solid imperfect specimens as are not reducible to known species. The fossil corals, corallines, sponges, &c. rank under this genus. See RELIQUIA.

ERISTALIS, the name of a stone, mentioned by Pliny and the ancients, and of which a very memorable quality is recorded by them, which is, that though it was naturally white, it would occasionally turn red.

ERISTICI, from *ερις*, dispute, in *Botany*, such authors as have attempted the study of that science in a philosophical way, and have been publicly engaged in disputes about the true foundation of its several distinctions, &c.

ERITHACE, a name given by the ancients to the yellow matter collected on the hinder legs of the bees after their excursions in search of the materials for their hives; we usually esteem this to be real wax, and the French call it *cire*, brute, or rough-wax; it is certain, however, that though the matter of which wax is to be formed is contained in this substance, yet the Dutch and some other nations have the most just idea of it, in calling it *pain des abeilles*, or the food of the bees.

This substance is only the farina of flowers, and no experiment has been able to separate real wax from it. The most probable opinion concerning it is, that it serves the bees as food, and that after this it is converted in their bowels into the substance called wax.

ERITHALIS, in *Botany*, Εριθαλις; is an ancient name of some plant now unknown, derived from *εριθαλις*, highly verdant, or beautifully leafy. Browne adopted it for the present genus, and was followed by Jacquin and Linnæus.—Browne Jam. 165. Jacq. Amer. 72. Linn. Gen. 95. Schreb. 130. Willd. Sp. Pl. v. 1. 996. Mart. Mill. Dict. v. 2. Juss. 206. Gærtn. t. 26. Class and order, *Pentandria Monogynia*. Nat. Ord. *Rubiacea*, Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, cup-shaped, with five teeth, permanent. *Cor.* of one petal, deeply five-cleft; tube very short; segments of the limb long, lanceolate, recurved. *Stam.* Filaments five, awl-shaped, spreading, scarcely so long as the corolla; anthers oblong. *Pist.* *Germen* inferior, roundish; style thread-shaped, compressed in the upper part, the length of the stamens; stigma acute. *Peric.* Berry globose, crowned with the base of the calyx, of ten cells, (sometimes but eight, *Gartner*.) Seeds small, solitary, pendulous.

Ess. Ch. Corolla in five deep recurved segments. Calyx cup-shaped. Berry inferior, of ten cells. Seeds solitary.

The species are, -

1. *E. fruticosa*. Linn. Sp. Pl. 251. (*E. odorifera*; Jacq. Amer. 72. t. 173. f. 23. *E. fruticulosa*; Brown. Jam. 165. t. 17. f. 3. *Sambucus ligno duro odoratissimo*; Plum. Ic. 247. t. 249. f. 2.)—Leaves obtuse. Flower-stalks all cymose, many-flowered.—Native of Jamaica, and other West Indian islands, growing near the sea-side, and very various in height and luxuriance, according to its situation. Stem shrubby, with round, smooth branches, leafy towards their extremities. *Leaves* opposite, stalked, obovate, entire, about two inches long, various in breadth, obtuse, smooth and shining. *Flowers* white, smelling (according to Jacquin) like the common lilac, growing many together, in long-stalked, axillary, cymose panicles, about the ends of the branches, but they are not terminal as Willdenow describes them. *Berries* purple, the size of a pea.—Jacquin

describes another species or variety, he is doubtful which, with inodorous flowers, whiter berries, and a more humble diffuse stem, growing on barren maritime rocks in the island of Curaçao. This we have never seen.

2. *E. polygama*. Forst. Prod. 17.—Leaves acute. Male flowers cymose; perfect ones solitary.—Gathered by Forster in the Society Islands.—That writer refers to the *Timonius*, Rumph. Amb. v. 3. 216. t. 140, as a narrower-leaved variety of his plant. This is, indeed, to all appearance, an *Erihalis*. Rumphius informs us that it grows in grassy open hilly places in Amboyna, and the neighbouring islands.

The stem is the height of a man. Leaves four or five inches long, and as broad as two fingers, acute at each end. Flowers of a dirty white. Berries yellowish-black, eaten by starlings and other birds. The roots are used by the natives to chew, along with a slight mixture of cloves, nutmegs and ginger, in their maritime excursions, in which they suffer much from cold and other inconveniences.

ERITRI, in *Geography*, a town of Asiatic Turkey, in the province of Natolia; 36 miles W. of Smyrna.

ERITZKA, a town of Russia, in the government of Irkutsk; 20 miles E. of Kirensk.

ERIVAN, called *Persian Armenia*, *Greater Armenia*, and *Eastern Armenia*, a province of Persia, about 200 leagues in length, and 60 in breadth. See ARMENIA.

ERIVAN, *Iravan*, or *Iriwan*, a city of Asia, and capital of Greater Armenia, or Erivan; situated in a plain, surrounded with mountains, and watered by two small rivers; large, dirty, and ill built, and but indifferently peopled: the ramparts are of earth; the fortress is encompassed with a wall of bricks, in which are a palace for the governor, and 800 houses, inhabited only by Persians; the Armenians have shops there, but must not remain during the night. The churches are small, and half buried in the ground, resembling catacombs; in the town and its environs they reckon 28 convents for devotees of both sexes, but they are poorly endowed.

ERIX, or ERYX, in *Ancient Geography*, a mountain of Sicily, situated towards the western part, near the sea. Solinus says, that it was consecrated to Venus. Polybius places it between Drepana and Palermo. According to Apollodorus, this mountain derived its name from a son of Venus, called *Erix*. It is now called "Monte St. Giuliano," or "Monte di Trapani."—Also, a town of Sicily, now "Trapani del Monte," situated on the summit of mount Eryx, difficult of access, and famous for a temple of Venus, called Erycina. Polybius and Strabo mention this town. Minos decorated this temple with superb sculpture, and enriched it with such noble offerings, as have claimed for him the honour of being its founder. The victims offered themselves voluntarily at the altar. The most beautiful women in the world were the priestesses, and the Roman senators, laying aside their characteristic severity, came hither to indulge in pleasure with the beautiful Sicilian females, persuaded they should thus make their offerings acceptable to the goddess, and render her propitious. In the time of Strabo the town and temple were much decayed. It is said that Eryx was destroyed by Hamilcar, who in the first Punic war, A. U. C. 493, removed its inhabitants to Drepanum, which he had built not long before. Nothing now remains but a paltry village, and some foundations of a temple.

ERIZZO, SEBASTIAN, in *Biography*, a noble Venetian, was particularly distinguished for his knowledge of the medallic science. He published, in 1559, in Italian, "A

Discourse upon Ancient Medals," which has been highly esteemed for its erudition. He contended for the difference between the medals and coins of the ancients. Erizzo was the author of a treatise on "Logic;" a translation of "Plato's Dialogues;" a discourse on "Civil Governments," and some other pieces. He died in 1585. Gen. Biog.

ERKELENS, or EREKELENS, probably *Herculanum*, in *Geography*, in the days of the Romans, is an ancient town of France, in the department of the Roer, chief place of a canton, in the district of Crévelt, with a population of 1340 individuals. It is at a distance of about three miles from the river Roer, 15 miles north of Juliers; its ancient fortifications were demolished by the French in 1674. The canton contains 48 communes, and 17,853 inhabitants.

ERLA, a small town of the kingdom of Saxony, in the circle of the Ertzgebirge, at the foot of the mountain called Rothenberg, remarkable for a rich mine of excellent iron, the best of the whole of this mountainous district. Its iron works are celebrated for casting the best ovens and frying-pans in Saxony; there is also a manufactory of cannon-balls. There was anciently a small town of the same name in Russia, in the government of Riga, not far from Dorpat; but it is now in ruins.

ERLACH, in French *Cerlier*, a small town of Switzerland, in the canton of Berne, at a distance of about three quarters of an English mile from the upper part of the beautiful lake of Biemme, is situated on the declivity of the Julimont, or Julius' mountain, for it is proved beyond contradiction that Julius Cæsar established upon this hill one of his strong entrenched camps. This elevation is also called Jolimont, pretty mount, from the beauty of the prospect, which can be no where more varied, or more interesting, on account of the number of picturesque contrasts which it affords. Travellers who wish to visit the famous island of St. Pierre, in the lake of Biemme, generally take a boat at Erlach. It has an ancient castle, which gave the title of barons to the illustrious Swiss family of the Erlachs, who, from the time of the intrepid Ulrich of Erlach, have held such a distinguished place in the annals of their country.

ERLANG, or ERLANGEN, a handsome town of Germany, in the circle of Franconia, in that part of the margraviate of Anspach Baireuth which was called the principality of Culmbach, on the river Rednitz, 18 miles N.W. of Nuremberg, and 30 miles S. of Bamberg. N. lat. 49° 38'. Until the peace of Tilsit, concluded in July 1807, between France and Prussia, this town, and the whole margraviate of Anspach Baireuth, belonged to the kings of Prussia, to whom it had been ceded by the last margrave, in 1792: but it is now at the disposal of the French emperor.

Erlang is divided into the old and new town; the latter is also called Christian Erlang, from the name of its founder, the margrave Christian Ernest, who built it in the year 1686 to accommodate several families of Protestant French refugees. The streets of both towns are regular and spacious: there are two handsome squares, and some fine churches. The principal manufactures established by the French refugees were those of hosiery and of hats, which are still flourishing. In 1742 the university of Baireuth was also removed to Erlang.

ERLAU, in Latin *Eger*, or *Agria*, a town of Upper Hungary, in the district of Heves, near which there is a fine hot mineral spring, which is used for bathing. It is the see of a bishop, and the seat of an university, the buildings of which are very fine: the professors are well accommodated, the lecturing rooms very good, and the chapel, library, and public hall extremely elegant. The see of Erlau is one of the

the richest in the kingdom. The town is in general ill built, the only good houses are those of the canons of the cathedral. There is, however, a Turkish tower in good condition. The only remarkable manufactures are those of wax and of leather. The neighbourhood of Erlau is famous for an excellent sort of Hungary wine, little inferior to the best Burgundy.

ERLEBACH, a river of Germany, which rises in the duchy of Stiria; 6 miles below Ips.

ERLEBACH, a town of Germany, in the circle of the Lower Rhine, and electorate of Mentz, on the Main; 3 miles N.N.W. of Clingenberg.

ERLENBACH, a town of Germany, in the circle of Franconia, and county of Wertheim; 10 miles N.N.E. of Wertheim.

ERMELAND, or ERMLAND, in Latin *Varmia*, one of the four subdivisions of that part of the kingdom of Prussia which is called Eastern Prussia. In ancient times, two-thirds of this country belonged to the bishops of Ermeland, who were princes of the German empire, and one-third to the chapter of the cathedral church of Frauenburg. The bishop enjoys still a very considerable income.

Ermeland is particularly remarkable for its hemp and flax, and its linen yarn, great quantities of which three articles are annually exported to England in time of peace. The principal towns are Frauenburg, the see of the bishop; Braunsberg, the chief city, which alone exports yarn to nearly the annual amount of two millions of guilders; Heilsberg, Allenstein, Rößel, Wormdit, &c.

ERMENEK, a town of Asiatic Turkey, in the province of Caramania; 63 miles S. of Cogni.

ERMENONVILLE, a small town of France, in the department of the Oise, chiefly remarkable for its beautiful park, and a castle, which derives some celebrity from having belonged to the handsome Gabrielle, mistress of king Henry IV. of France. But Ermenonville is become far more famous in modern times, for having been the last retreat of the eloquent and misanthropic Jean Jaques Rousseau, who died here on the 2d of July 1778, and to whom a handsome monument has been erected in a small island called the island of poplars, which is in the middle of a fine lake. This monument is remarkable for the beautiful simplicity of its inscription.

“ Ici repose l'homme de la nature et de la vérité.”

“ Here reposes the man of nature and of truth.”

ERMESIA, a name given to a composition used among the ancients, and famous for its effects in making people beget handsome children. It consisted of honey, myrrh, saffron, and palm-wine, all beaten together. This mass was to be taken mixed in milk. The women took it as well as the men, and many had great faith as to its effects.

ERMIJA, in *Geography*, a town of Spain, in the province of Biscay; 16 miles E.S.E. of Bilbao.

EKMIL, a town of Russia, in the government of Tambou; 44 miles S. of Tambou.

ERMIN, or ERMINE, in *Heraldry*, denotes a white field or fur, powdered or interspersed with black spots, called powdering. See *FUR*.

It is supposed to represent the skin of an animal of the same denomination. In effect, there is no animal whose skin naturally corresponds to the herald's ermin.

The animal is milk white; and so far is it from having spots, that tradition reports, that it will rather die, or be taken, than fully its whiteness. Whence its symbolical use.

But white skins having for many ages been used for the

linings of the robes of magistrates and great men; the furrriers at length, to add to their beauty, used to sew bits of the black tails of those creatures upon the white skins to render them the more conspicuous. Which alteration was introduced into armoury.

The fable spots in ermin are not of any determinate number, but they may be a greater or less, at the pleasure of the painter or furrrier.

ERMIN, an order of knights, instituted in 1450 by Francis I. duke of Bretagne, and formerly subsisting in France. The collar of this order was of gold, composed of ears of corn in saltier; at the end of which hung the ermin, with this inscription, *a ma vie*. But the order expired when the dukedom of Bretagne was annexed to the crown of France.

ERMINE', a cross erminé is a cross composed of four ermine spots.

It must be observed, that the colours in such arms are not to be expressed, because neither the cross nor the arms can be of any colour but a white and black.

Colombiere blazons it quatre queues d'ermine en croix. The editor of Guillim describes it thus; a cross of four ermines; or, more properly, four ermine spots in cross. It is the coat of Hurston in Cheshire.

ERMINE, *timbre of*. See *TIMBRE*.

ERMINE, in *Zoology*. See *MUSTELA Erminea*.

ERMINES is used by some English writers for the reverse of ermine, *i. e.* for white spots on a black field; but on what foundation nobody can tell; for the French, from whom we have our heraldry, have no such term; but call this black powdered with white contre-ermine; as denoting the counter, or reverse of ermine, which is white powdered with black.

ERMINEUM ANIMAL, *float*, or *ermine*, the creature whose skin is the ermine, so much esteemed as a fine fur.

This creature is properly a species of weasel, and is called by Mr. Ray, and other authors, *mustela candida*, the white weasel, and by Linnæus *mustela erminea*. It is in all respects like the common weasel, and is all over of a pure snow white, except the tip of the tail, which is of a beautiful black, and it has a little yellowish grey about the eyes, and a mark or spot of the same colour on the head, another on the shoulders, and a third near the tail. Its colour is, however, very different in degree and elegance, according to the season of the year. It is frequent about rivers, and in meadows, in those countries which produce it, and feeds on moles, mice, and other small animals. The skins and tails are a very valuable article of commerce in Norway, Lapland, and Russia, and other cold countries, where they are found in prodigious numbers, and regularly change their colour in winter, becoming white. In Siberia, they burrow in the fields, and are taken in traps, baited with flesh. In Norway they are shot with blunt arrows, or taken in traps. The float is sometimes found white in Great Britain, and called the white weasel. See *MUSTELA*.

ERMINITES should seem a diminutive of ermines, and naturally to signify little ermines; but it is otherwise. Erminites expresses a white field powdered with black; only that every spot has a little red hair therein.

Some authors use the word erminites for a yellow field powdered with black, which the French express much better by, or, *semée d'ermine de sable*.

ERMINOIS expresses an or field, with fable powdering.

ERMS, in *Geography*, a river of Germany, which runs into the Danube, four miles S.W. of Nurlingen, in the circle of Swabia.

ERMSLEBEN, a town of Germany, in the circle of Lower

Lower Saxony; and principality of Halberstadt; 14 miles S. E. of Halberstadt.

ERNANI, a town of Spain, in the province of Guipulcoa; 5 miles S. of Sebastian.

ERNATIA, a town of Asiatic Turkey, in the province of Natolia; 16 miles N. W. of Satalia.

ERNE, the name of a river in Ireland, which rises near the boundaries of the counties of Longford and Cavan, and passes through loughs Gawnah and Oughter in the latter county. From the last of these lakes it continues a northern direction till it flows into lough Erne, a little below Belturbet. The superfluous waters of this lake are discharged by a rapid current of about seven miles, which is also called Erne, and which falls into the bay of Donegal, below Ballyshannon.

ERNE-Lough, a lake of the county of Fermanagh, Ireland, which is supposed to occupy above 45,000 acres. It consists properly of two lakes connected by a broad winding channel of about six miles. The upper lake is nine miles long, and from one and a half to five wide; the lower lake extends in length about ten miles, and in breadth from two to eight. Both these lakes are full of islands, being said to contain from three to four hundred, the number varying according to the season, being more numerous in winter than in summer, on account of the greater height of the water. Some of these islands are large and inhabited, and many of them well wooded, so that the variety of interesting prospects afforded by them and the neighbouring coast is astonishing, and far surpasses the power of description. A canal to open the navigation from the lough to the sea has been projected, and would be attended with great advantage to the whole of Fermanagh and Cavan. It is also probable that a considerable part of the lake might be drained, and notwithstanding its beauty, it is a pity that so many acres should be unprofitable.

ERNE'E, a small town of France, in the department of Mayenne, chief place of a canton, in the district of Mayenne, with a population of 4740 individuals. It is situated on the river Ernée, 15 miles W. of Mayenne. The canton contains 6 communes and 15,053 inhabitants, on a territorial extent of 232 kilometres and a half.

ERNES, in our *Old Writers*, signify the loose scattered ears of corn that are left on the ground, after the binding or cocking of it.

It is derived from the old Teutonic *ernde*, harvest; *ernden*, to cut or mow corn. Hence *ern* is, in some places, to glean.

ERNEST, in *Biography*. See MANSFELD.

ERNEST Town, in *Geography*, a township of Upper Canada, in the midland district, the finest above Kingston, sheltered from lake Ontario by Amherst island, which lies in its front.

ERNESTI, JOHN AUGUSTUS, in *Biography*, was born in August, 1707, at Tennstadt, where his father was superintendant. He studied at Pforta, and soon displayed uncommon talents; he afterwards applied himself to the study of theology at Leipzig, and took his degree of M. A. in the year 1730. In 1734, having been elected rector of Thomas's school in the room of Gesner, ancient literature, and those branches of knowledge connected with it, became the principal objects of his pursuit. The successful application of his talents in this department of knowledge caused him to be chosen, in 1742, extraordinary professor of ancient literature, in 1756 he was elected public professor of eloquence, and in 1758, he was made doctor and professor of theology. He died in the year 1781, having, till within the last two or three years, been incessantly engaged

in the laborious discharge of his public duties. For twenty years and more he passed the greater part of each day in instructing others, yet he found ample time for the publication of many original works, and for editing various ancient authors. Among the latter may be mentioned, 1st, the *Memorabilia of Xenophon*, which has been frequently republished in this and other countries. 2d, *Cicero's Opera omnia cum clave*, in 6 vols. The *Clavis* has been published separately. Ernesti, in preparing this work for the press, employed the best and oldest editions of Cicero, as well as several MSS.; he examined critically the text of Gruter, corrected in it a great many faults, and in his short notes, he has in various places illustrated, and in others restored the original. He also gave the world new editions with notes of Suetonius, Tacitus, Homer, &c. He published *Aristophanis Nubes*, cum *scholiis antiquis et Prefat*; *Hederici Lexicon*, multis *vocabulorum millibus auctum*; a *New Theological Library*, in 11 volumes; and "*Institutio interpretis Novi Testamenti*," which has passed through several editions. Alberti of Leyden was so much delighted with this, that he called it "*The Golden Work*." A new edition of it was published in Holland within a few months after it was printed at Leipzig. The extensive talents and sober judgment of Ernesti enabled him not only to embrace every department of literature, but to examine and illustrate many of its obscurities and difficulties. He possessed a ready and retentive memory, and, above all, an honest and upright heart. "*Though*," says his biographer, "*the seriousness of his countenance bespoke a character hostile to every kind of levity, and born for labours that require great vigour and exertion, he was a friend to cheerfulness, and his company, on account of his easy behaviour and good humour, which was often heightened by Ciceronian wit, but confined within the boundaries of virtue and decency, made his conversation much sought after, and highly agreeable.*" *Gen. Biog.*

ERNODEA, in *Botany*, from *ἐρνώδης*, branched, so that it ought rather to be written *Hernodea*. Swartz. *Prod.* 29. *Fl. Ind. Occ.* v. 1. 223. Schreb. 788. Willd. *Sp. Pl.* v. 1. 611. Mart. *Mill. Dict.* v. 2. Sm. *Prod. Fl. Græc. Sibth.* v. 1. 98. Class and order, *Tetrandria Monogynia*. Nat. Ord. *Rubiaceæ*.

Gen. Ch. *Cal.* Perianth small, superior, in four deep, upright, acute, equal, permanent segments. *Cor.* of one petal, falver-shaped; tube elongated, quadrangular; limb in four deep, lanceolate, recurved segments. *Stam.* Filaments four, inserted into the tube towards the middle, awl-shaped, longer than the tube; anthers erect. *Pist.* Germen square, inferior; style thread-shaped, about as long as, or longer than the stamens; stigma obtuse, notched. *Peric.* Berry roundish, crowned with the calyx, having a furrow at each side, and consisting of two cells. *Seeds* solitary, hemispherical, striated.

Ess. Ch. Corolla of one petal, falver-shaped. Calyx in four deep segments. Style simple. Berry inferior, of two cells. Seeds solitary.

1. *E. littoralis*. Swartz. *Fl. Ind. Occ.* v. 1. 224. t. 4. Vahl. *Symb.* v. 2. 28. (*Thymelæa humilior, foliis acutis atrovirentibus*; Sloane *Jam.* v. 2. 93. t. 189. f. 1, 2.)—Stem square, smooth. Leaves nearly sessile, acute, with a spinous point. Gathered by Sloane, Browne, and Swartz, in Jamaica. The latter informs us that it grows in gravelly places by the shore, or on calcareous rocks. *Root* perennial. *Stems* procumbent, creeping, rather woody, with numerous, long, creeping or pendulous branches, which are straight, square, smooth, somewhat jointed, not much divided, but bearing numerous, alternate, short, leafy, simple, lateral branches. *Leaves* crowded, opposite, crossing each other

other in pairs, nearly sessile; about an inch or more in length, elliptic-lanceolate, acute at both ends, entire, very smooth, ribbed, rigid, of a dark green, tipped with a spinous point. *Stipulas* united with a stem between the very short foot-stalks, each crowned with three bristles, the middle one longest. *Flowers* axillary, solitary, sessile, yellowish. Many of them, according to Dr. Swartz, have no pistils.

2. *E. montana*. Sm. Fl. Græc. Sib. v. 2. t. 143, unpublished. Prod. n. 343. (*Asperula calabrica*; Linn. Suppl. 120. Willd. Sp. Pl. v. 1. 577. L'Herit. Stirp. v. 1. 65. t. 32. *Rubeola cretica foetidissima frutescens myrtifolia, flore magno suaverubente*; Tourn. Cor. 5.)—Stem round, downy. Leaves stalked, blunt, pointless.—Native of mountainous places in Crete, Sicily, and the south of Italy. Much smaller than the last, except in its *flowers*, which are larger, clustered about the ends of the branches, and of a fine rose-colour. The *stems* are much branched, woody, decumbent. *Leaves* on short stalks, opposite, about half an inch long, elliptic-lanceolate, bluntnish at both ends, entire, revolute, without any terminal spine, much more pliable than in the former; dark green above; pale beneath; roughish occasionally. When bruised they have a very disagreeable stercoraceous smell. *Stipulas* with a simple lanceolate point. *Branches* more or less downy when young.—Authors have greatly differed about the genus of this plant. By the older ones it has been taken for a *Rubia*, a *Valeriana*, a *Thymelea*, and a *Nerium* or *Oleander*; by modern writers it has been referred to *Asperula*, *Sherardia* and *Pavetta*. We hope to be nearer the truth than our predecessors; at least its technical generic characters agree well with Swartz's *Ernodea*, nor do we find any great discordance in the habit.—This beautiful plant emulates the *Daphne Cneorum* in colour and general aspect, and would be scarcely less admired in our gardens, to which it is, as yet, a stranger.

ERNSPACH, in *Geography*, a town of Germany, in the circle of Franconia, and principality of Hohenloe; six miles N. of Okringen.

ERNSTEIN, a castellated town of Germany, in the circle of the Lower Rhine, and electorate of Cologne; eight miles E. of Lintz.

ERNSTHOFEN, a town of Germany, in the circle of the Upper Rhine, and principality of Hesse Darmstadt; 10 miles S. of Darmstadt.

ERNSTTHAL, a small town of the kingdom of Saxony, in the county of Schonburg, close by Hohnstein, at the foot of a mountain called the Pfaffenberg, with a population of about 2000 individuals. It has a few cotton and linen manufactories.—Also, a small town of Germany, in the duchy of Saxe-Coburg, which has a considerable glass manufactory; in the space of thirteen weeks, or three calendar months, they make 216,000 glasses, 1000 of which used to be sold, in 1788, for 3½ rix dollars, or not quite twelve shillings sterling.

ERODINUM, a word used by some of the enthusiastic writers in alchemy, to signify the prognostic, good or bad, of any operation.

ERODIUM, in *Botany*, from *ερωδιος, a heron*, because the fruit resembles the head and beak of that bird. For a similar reason it is called in English Stork's-bill. L'Heritier. Geraniolog. unpublished. Ait. Hort. Kew. v. 2. 414. Sm. Fl. Brit. 727. Willd. Sp. Pl. v. 3. 625. Sibth. Oxon. 211. (*Geranium*; Linn. Gen. 350. Schreb. 458. Juss. 268. Gaertn. t. 79, *moschatum*.) Class and order, *Monadelphia Pentandria*. Nat. Ord. *Cruinales*, Linn. *Gerania*, Juss.

Gen. Ch. Cal. Perianth inferior, of five ovate, pointed,

concave, permanent leaves. *Cor.* Petals five, obovate, spreading, rather longer than the calyx, generally more or less irregular. *Nectary* of five glands between the petals. *Stam.* Filaments 10, awl-shaped, united by their base into a sort of cup; five of them fertile, nearly as long as the petals; the alternate five shorter and barren; anthers five, oblong, versatile. *Pist.* Germen superior, with five furrows, beaked; style central, awl-shaped, spirally furrowed, as long as the stamens, permanent; stigmas five, reflexed. *Peric.* Capsules five, aggregate, membranous, obovate, vertical, separating at their inside, sharp-pointed at their base, each tipped at its summit with a long, linear, flat, pointed, rigid awn, hairy on its inside, and at length spirally twisted, adhering by its ovate-oblong.

Eff. Ch. Calyx of five leaves. Petals five. Nectariferous glands five. Barren filaments five. Fruit beaked, of five aggregate capsules, each tipped with a long spiral awn, bearded on the inside.

Linnaeus in his *Genera Plantarum* had long ago indicated a division of his genus *Geranium* into several natural sections, distinguishable by characters in their fructification and inflorescence. The late learned botanist Monf. L'Heritier, pursuing the idea, divided that genus into three, each of them as naturally and distinctly defined as any in the whole system, and although the convulsions of his country, and his own premature death, prevented his publishing an elaborate work on the subject, he had fortunately conferred by letter with the intelligent editors of the *Hortus Kewensis*, and with the writer of the present article, so that his intention has been carried into effect, both in that work and the *Flora Britannica*. Of these three genera *Geranium* with its 10 fertile stamens, regular flower, and recurved naked awns, consists of what are usually called European *Geraniums*, bearing but one or two flowers on a stalk; *Pelargonium* with its seven fertile stamens, irregular flower, tubular nectary, and spiral bearded awns, comprehends what are generally called Cape *Geraniums*; while the present genus is made up of the Linnaean *Gerania cicutaria*.

Three species of *Erodium* are natives of Britain.

1. *E. cicutarium*. Engl. Bot. t. 1768. Hemlock Stork's-bill. (*Geranium cicutarium*; Linn. Sp. Pl. 951. Curt. Lond. fasc. 1. t. 51.) "Flower-stalks many-flowered; leaves pinnate; leaflets sessile, pinnatifid, cut." Common in waste ground. In sandy places near the sea its petals are generally white, or their usual rose-colour is elegantly diversified with a green spot on two or three of them. The herb is fetid, prostrate and annual, with finely divided leaves.

2. *E. moschatum*, Engl. Bot. t. 902. Musky Stork's-bill. (*Geranium moschatum*; Linn. Sp. Pl. 951.) "Flower-stalks many-flowered. Leaves pinnate; leaflets nearly sessile, elliptical, unequally cut." Wild in the mountainous pastures of Yorkshire and Westmoreland, but in other places it is usually the outcast of gardens, where it has often been cultivated for the sake of the strong musky scent of its herbage. The *flowers* are smaller and less ornamental than those of the preceding; *leaves* larger, paler, and more viscid.

3. *E. maritimum*, Engl. Bot. t. 646. Sea Stork's-bill. (*Geranium maritimum*; Linn. Sp. Pl. 951.) "Flower-stalks barely three-flowered. Leaves heart-shaped, cut, crenate, rough. Stems depressed." Native of sandy sea-shores in various places, flowering all summer long. When brought into a garden it becomes wonderfully luxuriant. The *root* is perennial. *Petals* white or reddish, for the most part much smaller than the calyx leaves.

Willdenow has 34 species of this genus in all. Most of them

them abound in the warmer countries of Europe, and the northern part of Africa, and several are cultivated with us for ornament, as *E. gruinum*, (*Geranium creticum*; Ger. em. 943), a hardy annual with large blue flowers; *E. hymenodes*; Andr. Repof. t. 413, which requires a greenhouse, and is perennial. Three species are natives of the Cape of Good Hope, viz. the most beautiful *E. incarnatum*, Ait. H. Kew. v. 2. 415. Curt. Mag. t. 261. (*Geranium incarnatum*; Linn. Suppl. 306.) This is a tender greenhouse plant, and therefore not very common, but worthy of all attention for the delicate hues, and eye-like pencilling, of its blossoms. The other two Cape species are *arduinum*, (*Geranium arduinum*; Linn. Sp. Pl. 952.) very little known to botanists, and never introduced into the gardens of Europe; and *ribifolium*, Jac. Ic. Rar. v. 3. t. 509.) an inconspicuous flower, not much likely to excite the attention of cultivators.

**ERODIUS**, in *Entomology*, a genus of the Coleopterous kind, established by Fabricius. These insects are generically distinguished by the following character: the antennæ moniliform; feelers four; jaws horny, truncated, and bifid; lip horny and emarginate. This is the Fabrician definition, to which may be added that the body is roundish, gibbous, and emarginate; thorax transverse; wing-cases closely united, and longer than the abdomen.

#### Species.

**TESTUDINARIUS**. Black; wing-cases rough, the sides covered with whitish dust. Fabr.

An insect of large size, found at the Cape of Good Hope; the wing-cases are very gibbous, with small raised dots.

**GIBBUS**. Black; wing-cases with three raised lines. Fabr. Remarkable for the gibbosity of its form, and the obtusity of the wing-cases; it is of moderate size; and has the anterior shanks armed with a strong tooth in the middle and at the tip. The species inhabits Arabia.

**PLANUS**. Black; wing-cases with a single raised line. Fabr.

Native of the same country as the former. The anterior shanks not armed with a spine.

**MINUTUS**. Black; wing-cases perfectly smooth. Fabr.

Small thorax with two impressed dots on the back; legs unarmed. Inhabits the eastern parts of the world.

**MURICATUS**. Gibbous, black; wing-cases muricate. Fabr.

A species described in the Fabrician Suppl. Ent. from the cabinet of Lund. It is a native of the Cape of Good Hope; in size and appearance resembles *E. gibbus*. The head and thorax smooth.

**EROPHEEVO**, in *Geography*, a town of Russia; in the government of Irkutsch; 60 miles N. of Balaganskoi.

**EROS**, of *eros*, love, in *Mythology*, one of the two chiefs over all the other cupids, being the cause of love. See **ANTEROS**.

**EROSION**, in books of *Surgery*, we often find this expression used synonymously with the term ulceration.

**EROSION**, in *Geology*, according to Mr. Kirwan, (*Geol. Ess.* 230 and 285,) denotes a solution or melting of the softer calcareous particles by water, by which he accounts for the formation of the vast caverns and grottos to be found in the Derbyshire lime-stone rocks, and those of other countries. M. de Saussure, in his *Agenda* (*Journal des Mines*, N<sup>o</sup> 2c.) directs the attention of geological travellers to the sides of valleys (§ 12.) to search for the vestiges of the erosion of water: by which we might understand a mechanical sweeping or washing away of strata, as well as a solution or melting as above.

**EROSUM FOLIUM**, among *Botanists*. See **LEAF**.

**EROTESIS**, *Ἐρωτησις*, in *Rhetoric*, the same figure with *Interrogation*. Every interrogation or question is not figurative; but it becomes figurative, when the same thing may be expressed in a direct manner; but the putting it by way of question gives it much greater life and spirit. As when Cicero says, (in *Catal.* i. c. 1.) "Cataline, how long will you abuse our patience? Do not you perceive your designs are discovered?" He might have said, "You abuse our patience a long while; you must be sensible your designs are discovered." But it is evident how much this latter mode of expression falls short of the force and vehemence of the former. Thus also, when Medea says, "I could save; and do you ask, if I can destroy?" Had she merely said, "I could save, and I can destroy," the sentence would have been flat, and very unfit to express the rage and fury in which the poet there represents her. (*Quint. Inst. Orat.* l. viii. c. 5.) This figure is suited to express most passions and emotions of the mind, as anger, disdain, fear, desire, &c. It serves also to press and bear down an adversary. This figure likewise diversifies a discourse, and gives it a beautiful variety, by altering the form of expression, provided it be neither too frequent, nor continued too long. Besides, the warm and eager manner in which it is expressed enlivens the hearers, and quickens their attention.

**EROTEUM**, in *Botany*, perhaps from *ἑρωτίζω*, to question, in allusion to its doubtful nature at first sight, being very like *Thea* till the fruit is investigated. Swartz. *Prod.* 5. The author, however, being himself, as it seems, dissatisfied with this name, has, in his *Fl. Ind. Occ.* v. 1. 971, changed it to **FREZIERA**, which see.

**EROTIA**, *Ἐρωτία*, a festival among the Greeks, in honour of Cupid, being celebrated every fifth year with sports and games.

**EROTIANUS**, in *Biography*, the author of a glossary, containing an explanation of all the words used in the writings of Hippocrates, lived in the first century of the Christian era, in the reign of Nero, and dedicated his work to Andromachus of Crete, who was physician to that emperor. It was printed at Venice, in 1566, in 4to. with the notes of Barth. Eustachius, under the title of "Vocum, quæ apud Hippocratem, collectio, et ejus operum in septem sectiones distributio." The glossary of Erotian was also annexed to the edition of Hippocrates, published by Foesius at Geneva, in 1657. Haller. *Bibl. Med. Eloy.*

**EROTIC**, derived from *ἔρως*, love; whence *ἑρωτικός*, is applied to any thing which has a relation to the passion of love.

In *Medicine*, we particularly use the phrase delirium eroticum, for a kind of melancholy contracted through excess of love.

Though, among the several species of pulses, there be no amorous pulse, that is, no pulse peculiar to that passion; yet we can certainly discover where the disorder is erotic, by the beating of the pulse, which, in that case, is changeable, unequal, turbulent, and irregular. Speak to the patient of the person he loves, and his pulse instantly changes, becoming higher and quicker; and the minute you change the conversation, the pulse is lost again, and is disturbed anew.

**EROTIDIA**, *ἑρωτιδία*, the same with *erotia*.

**EROTOMANIA**, in *Medicine*, a term used by some writers to denote that modification of insanity, of which the passion of love is the origin, and in which the love of a particular individual constitutes the predominant idea. Sauvages treats of this form of derangement under the name of *melancholia amatoria*; (see his *Nofol. Meth. Class.* viii. Gen. xix. Spec. 2.) Sennertus under that of *amor*

*infans*, &c. The word is derived from *ignis*, love, and *manus*, mania, madness.

This disease is distinguished from satyriasis and nymphomania, if indeed such maladies have any existence, inasmuch as the patient, so far from being urged by libidinous desires, contemplates the object of his affection with reverence and distant admiration, as if he were a divinity; he would spend his days in doing homage to her perfections, and deems food, sleep, and the affairs of the world of little comparative moment. As a remedy for this species of insanity, low and light diet has been recommended. Ovid has advised the performance of a long journey, during which a constant change of scene, and the absence of all objects, with which the recollection of the individual beloved, might tend to restore the mind to its usual condition: constant occupation of body or mind, "qui vis sanari, res age, tutus eris;" and the admonitions of the wife in regard to the loss of health, fortune, and character, which must attend such hallucination, have also been suggested. The former part of the advice may be sometimes beneficial, but those who are most experienced in the treatment of the insane, well know how little benefit is produced by reasoning with madmen. See MELANCHOLY.

EROTYLOS, in *Natural History*, the name of a stone, of which we have no description left us, but which the ancients are said to have used in divination.

EROTYLUS, in *Entomology*, a genus of Coleoptera in the Fabrician system, allied, and in some degree confounded, with the two Linnæan genera *Chrysomela* and *Coccinella*, and arranged by Gmelin under that of *Cryptocephalus*. The antennæ are filiform; feelers four and unequal, the anterior longer and hatchet-shaped; jaws horny and bifid; lip horny, short, dilated at the tip, truncated, and somewhat emarginate; body suboval. The transformations of these insects are unknown, in the perfect state they are found generally on flowers. Three of the species are described by Linnæus, the remainder principally by Fabricius.

Species.

GIGANTEUS. Oval, black; wing-cases with numerous fulvous dots. Fabr. *Chrysomela gigantea*, Linn. *Coccinella gigantea*, Sulz. Native of India.

CANCELLATUS. Black; wing-cases yellow, reticulated with black. Fabr. Large and roundish; inhabits Brazil.

HISTRIO. Deep black; wing-cases barred with black and yellow, a scarlet spot at the base and tip. Fabr.

A species of large size, an inhabitant of Cayenne.

LUGUBERIS. Testaceous; antennæ and shanks black. Fabr. Native of America.

GIBBOSUS. Black; wing-cases yellowish with black dots; band in the middle and at the end black. Fabr. *Chrysomela gibbosa*, Linn. *Coccinella*, Gronov.

An insect of considerable magnitude, the wing-cases of which are remarkably gibbous, and the thorax impressed on each side; it is a native of South America.

6-FASCIATUS. Oval, black; wing-cases with six waved fulvous bands, the anterior one interrupted. Fabr.

Inhabits Cayenne.

NOTATUS. Black; wing-cases with a yellow band in the middle spotted with black, and marked with red at the base. Fabr. Native of South America.

CONCATENUS. Black; wing-cases reticulated with yellow and black, and marked with two black bands. Fabr. Mant. Inf. Country unknown; the body large.

5-PUNCTATUS. Oval; wing-cases black with five red dots. Fabr. Inhabits America.

PUNCTATISSIMUS. Black; wing-cases yellow with numerous black dots. Fabr.

Described from the Hunterian cabinet: an American species.

VARIUS. Black; wing-cases punctured, spotted with fulvous in the middle. Fabr. Inhabits Surinam.

GEMMATUS. Black; wing-cases with numerous fulvous dots; thorax variolous. Fabr.

An insect of moderate size, found in Cayenne.

MACROCHEIROS. Black; wing-cases with alternate black and yellow bands; fore legs very long. Fabr.

Native of India.

ABDOMINALIS. Black; wing-cases yellow with four waved black bands and a distinct black dot. Fabr.

A Brazilian species, in size resembling *E. fasciatus*, and having the abdomen yellow with two lines of black dots.

FASCIATUS. Black; wing-cases with three yellowish bands. Fabr.

From the Banksian cabinet: the native place unknown: size moderate.

ZEBRA. Yellowish; head, base of the thorax, and three bands on the wing-cases with the legs black. Fabr. Mant.

ALTERNANS. Black; wing-cases with two yellow bands, the anterior one dotted with black. Fabr.

SURINAMENSIS. Black; wing-cases red and immaculate. Fabr. Native of Surinam.

LIMBATUS. Oblong, black; margin of the thorax and border of the wing-cases yellow. Fabr.

South American species; head yellowish with a black frontal spot; thorax smooth with a broad sinuate lateral margin.

NEBULOSUS. Black; thorax, and wing-cases varied with ferruginous. Fabr.

Inhabits the same country as the preceding.

DILATATUS. Oblong, black; thorax and wing-cases ferruginous. Fabr.

Native of the Cape of Good Hope. The antennæ are brown, at the base ferruginous; wing-cases smooth; and much broader than the body.

MORIO. Oblong, black, and immaculate. Fabr.

This, and the four following species, are natives of New Holland. These are described by Fabricius from the Banksian cabinet, and are represented in the volume of "Donovan's General Illustration of Entomology, devoted to the Insects of the Australasian regions."

SMARAGDULUS. Oblong, black; wing-cases striated and green.

AMETHYSTINUS. Oblong, black; thorax and wing-cases blue; resembles the last; front retuse; wing-cases with punctured striae.

BICOLOR. Oblong, black; bronzed above.

CUPREUS. Oblong, black; thorax and wing-cases coppery.

RUFIPES. Oblong, black; legs pitchy. Fabr. Mant. Inhabits Kiel.

FLAVIPES. Oblong, glossy green; antennæ and legs yellowish. Native of Jamaica, in the Banksian cabinet.

EROWA, the name of a kind of nettle which grows in the mountains at Otaheite in the South Sea, with which the inhabitants make fishing lines, which serve to hold the strongest and most active fish, and are much stronger than our silk lines of twice the thickness.

See ERBACH, in *Geography*.

ERPENIUS, THOMAS, in *Biography*, was born at Gorcum, in Holland, in the year 1584. His parents, natives of Bois-le-Duc, were, on account of their conversion to the Protestant religion, obliged to withdraw from that place, to one more favourable to the rights of private judgment. They provided their son with a good education in the rudiments of learning, and when they discovered in him a pro-

penity for literary pursuits they sent him to Leyden, where he felt so dissident of succeeding in his studies, that for some time he determined to relinquish them. Fortunately his desire for knowledge overcame his modesty, and he applied himself with so much diligence, that he obtained the highest praise of his different tutors, and excited their surprize at his extraordinary progress. He excelled in metaphysics, but his fame with posterity is built on the skill which he acquired in the oriental languages. After availing himself of all the advantages which the university of Leyden afforded, he travelled for farther improvement in foreign countries. In England he became acquainted with Bedell, who was celebrated for his knowledge in Hebrew and rabbinical learning. In France he improved himself in his knowledge of the Arabic tongue; and in Italy he improved his acquaintance with the Hebrew language, by conversing with some learned Jews, and made himself master of the Persian, Turkish, and Ethiopic tongues. After spending several years in foreign countries, Erpenius returned to Holland, where he was elected professor of the oriental languages in the university of Leyden. This was in the year 1612, and very shortly after his appointment he set up a press for the printing of works in the Eastern literature. In the year 1620 he was sent by the States General on different journeys into France, to engage Peter du Moulin, or Andrew Rivet, to undertake the theological professorship at Leyden. After this he was appointed oriental interpreter to the States, and was employed to translate the letters addressed to them from Asia and Africa, and to write such as were sent by them to the sovereigns in those parts of the world. He was frequently invited into Spain by the sovereign of that country, to explain certain inscriptions in the Arabic language on the Moorish buildings and monuments in that country, and the emperor of Morocco is said to have been highly pleased with the purity and beauty of his style, and to have exhibited his letters as objects of real curiosity. He died in the year 1624, when he was only 48 years of age. His works are numerous, and have given him a high reputation among the learned. They are enumerated by Moreri, and other biographical writers, and we are informed that he projected an edition of the Koran, with a Latin version and notes, likewise an Arabic grammar and lexicon, which his death prevented him from executing. Gerard-Jean Vossius pronounced over him a funeral oration. Moreri.

ERPIS, or HERPIS, in *Ancient Geography*, a town of Africa, in Mauritania Tingitana. Ptolemy.

ERRA, in *Geography*, a town of Portugal, in the province of Estremadura, on a river of the same name; 22 miles S.E. of Santarem.—Also, a river, which runs into the Latas, 12 miles E. of Salvateira; in the province of Estremadura.

ERRABARI, a town of Egypt; 10 miles N.W. of Cairo.

ERRAINE, a town of Egypt; two miles E. of Tahta.

ERRANT, in *Law*, the same with itinerant; the term is attributed to judges who go the circuit; and to bailiffs at large.

ERRANTS, *knight*. See KNIGHT.

ERRATA, a list usually placed at the beginning or end of a book, containing the faults that have escaped in the impression, and, sometimes, even in the composition of the work.

Lindenberg has an express dissertation on typographical errors, "De Erroribus Typographicis;" in which he observes, that there is no book exempt from them, not

even the sacred books. He sets himself to enquire into all the causes thereof; and proposes means to prevent them, but he advances nothing on that article but what is either common, or impracticable.

ERRATIC, in *Astronomy*, an epithet applied to the planets, which are called erratic, or wandering stars, in contradistinction to the fixed stars.

ERRATIC fevers, in *Medicine*, a term used to express such fevers as, according to the language of medical writers, observe no regular type, that is, are not determinate either in their attacks, or in their general period. They are thus called by way of distinction from the typic fevers, which are regular in both. See FEVER.

ERRATIC winds. See WIND.

ERRHINE, in the *Materia Medica*, from *er*, *in*, and *rhin*, the nose, is a term applied to those substances which are introduced into the nose, for the purpose of exciting a discharge from the passages. When they excite sneezing, the medicines of this class have been called ptarmica, and sternutatories; and, from the discharge which they occasion, they have been termed apophlegmatica, and, in barbarous Latin, caput-purgia.

Errhines, by stimulating the exhalent vessels and the mucous follicles of the Schneiderian membrane, which lines the internal surface of the nose, and the cavities adjoining it, excite those vessels and follicles to pour out their fluids more copiously than usual. The discharge is sometimes of a mucous, and sometimes of a thinner fluid; it is often attended with sneezing, but sometimes is procured without. This, however, implies no difference in the operation, except as to the stronger or weaker irritation of the medicine employed. For although when sneezing is excited a larger evacuation is often produced, yet the effects of errhines are not altogether proportional to the sensible irritation which they occasion. See Alston, *Mat. Med.* vol. i. sect. 8.

The evacuation produced by these medicines consists not merely in emptying the mucous follicles of the lining membrane of the nose of their contents, but in augmenting the secretion: whence, agreeably to the laws of the circulation, a greater afflux of fluids to those parts is necessarily occasioned, and therefore a diminution of the fluids in the neighbouring vessels. In this way Dr. Cullen explains the fact, that errhines often give relief to rheumatic pains in the neighbouring parts, especially to the tooth-ach, as well as to some forms of head-ach, pains of the ear, and ophthalmia. "How far their effects may extend," he says, "cannot be exactly determined; but it is probable that they may operate more or less on the whole vessels of the head, as even a branch of the carotid passes into the nose: and independent of this, it is not improbable that our errhines may have been of use in preventing apoplexy and palsy; which at least is to be attended to so far, that whenever any approach to these diseases is suspected, the drying up of the mucous discharge should be attended to, and, if possible, restored." Cullen's *Mat. Med.* vol. ii. p. 436.

The nicotiana, or tobacco, as it is commonly prepared for persons who amuse themselves by snuffing, may be conveniently employed, with people unaccustomed to it, as an errhine; but repetition soon diminishes its power, and renders it useless. It produces a different degree of discharge in different people, even of those who use it habitually; and Dr. Cullen states, from his own experience, "that whenever the discharge has been considerable, the laying aside snuffing, and therefore suspending that discharge, may have very bad effects."

The article most commonly employed as an errhine, is the *Asarum esarabacca*, snuffed up the nose every evening, for a short time, in the quantity of three grains. Quincy observes,

erves,

*Serves*, that its pungency is not immediately felt upon taking, but after some time it makes the nose run very much. In larger quantities it sometimes brings blood, and even occasions a swelling of the whole head. This last effect, however, has been oftener produced by the *Euphorbium*, a still more acrid errhine. Dr. Cullen, speaking of these severe effects, says, "I have seen some instances of megrims, ophthalmias, and particularly tooth-achs, cured by the violent operation of errhines; but I never thought it safe to imitate the practice." The *white hellebore*, in very small quantity, is also an acrid errhine.

ERRIFF, in *Geography*, a province of Africa, in the country of Fez. See RIF.

ERRIPSIS, from *εἶπω*, *I precipitate*, in *Medicine*, is used in different senses, sometimes for a weakness of the whole body, sometimes only of some one part. When applied to the whole body, it expresses that utter dejection and prostration of strength which makes a man fall down like a dead carcass; and, when applied to the eyes, it expresses such a debility, as renders it impossible to keep them open.

ERROAD, in *Geography*, a town of India, in the country of Coimbatore; 39 miles E.S.E. of Damicotta, and 48 N.E. of Coimbatore.

ERROL, a small uninhabited town of America on lake Umbagog, on the north-easternmost settled part of Grafton county, in New Hampshire, incorporated in 1774.

ERROMANGO, an island in the Southern Pacific ocean, being one of those called the "New Hebrides," 18 leagues from Sandwich island, and 24 or 25 leagues in circuit. The middle of it lies in S. lat.  $18^{\circ} 54'$ . E. long.  $169^{\circ} 19'$ , and it is of a good height. Captain Cook anchored in a bay of this island; and he found that although the behaviour of the inhabitants was at first friendly, their real intentions were very different. They were armed with clubs, spears, darts, bows and arrows, and seemed determined to employ them in a hostile manner. On this account it became necessary for the captain to give orders to his men to fire upon the assailants. At length they were so terrified as to withdraw and make no farther appearance. Those islanders, it was observed, seemed to be of a different race from those of Mallicollo, and they spoke a different language. They are of a middle size, with a good shape, and tolerable features. Their colour is very dark, and their aspect is not improved by their custom of painting their faces, some with a black, and others with a red pigment. Their hair is curly and crisp, and somewhat woolly. The few women, who were seen and who appeared to be ugly, wore a kind of petticoat, made either of palm leaves, or of a similar plant; but the men, like those of Mallicollo, were almost entirely naked. On account of the treacherous behaviour of the inhabitants of Erromango, captain Cook called a promontory, or peninsula, near which the skirmish happened, "Traitor's Head." This is in the N.E. point of the island, and is situated in S. lat.  $18^{\circ} 43'$ , and E. long.  $169^{\circ} 28'$ .

ERRONAN, or FOOTOONA, the most eastern island of all the Hebrides, appeared to captain Cook to be about five leagues in circuit, of a considerable height, and flat at top. On the N.E. side is a little peak seemingly disjoined from the isle; but which was thought to be connected by low land. It is distant in the direction of N. by E.  $\frac{1}{2}$  E. 11 leagues from Port Resolution in the island of Tanna.

ERROR, a mistake of the mind in giving assent to a thing, or proposition, which is not true. See FALLACY.

Some philosophers define error an act of the mind, whereby things that should be joined are separated; or, things that should be separated, are joined; or a wrong judgment, disagreeing with the things whereon it is passed.

Error stands in opposition to truth, which consists in an agreement between the proposition and the thing whereof it is affirmed or denied.

However, a bare failure, or non-attainment of truth, does not constitute error; that being common both to ignorance and doubting.

Error only stands distinguished from *falsehood*, in that the former is in the mind, and the latter only in the proposition.

The great origin of all error, *i. e.* of believing that to be true which is false, is a liberty, or power, in the human mind, of giving its assent to ideas, to propositions, that are obscure, as if they were perspicuous and plain.

Particular causes of error are, inadvertency, ignorance, impatience, interest, authority, education, &c. See FAITH, PROBABILITY, OPINION.

Against all which, there is this one general rule or caution laid down by F. Malebranche and others; *viz.* never to give our full assent to any proposition, unless the evidence for it be so strong, as that we can no longer withhold it, without incurring the secret reproaches of our own reason.

Mr. Locke reduces the causes of all our errors to these four; *viz.* 1. Want of proofs. 2. Want of ability to use them. 3. Want of will to use them. And, 4. Wrong measures of probability.

F. Malebranche considers five occasional causes of error, or rather of five different kinds of errors, accommodated to the different manners we have of perceiving things. 1. Errors of sense. 2. Of the imagination. 3. Of the understanding. 4. Of our inclinations. And, 5. Of the passions. See SENSE, IMAGINATION, UNDERSTANDING, INCLINATION, and PASSION.

ERRORS, *popular*. See POPULAR.

ERROR, in *Law*, generally denotes a fault, or oversight, either in pleading, or in process; upon either of which is brought a writ, by way of remedy, called a *writ of error*; in Latin, *de errore corrigendo*.

A writ of error lies for some supposed mistake in the proceedings of a court of record; for, to amend errors in a bafe court, not of record, a writ of "false judgment" lies. The writ of error only lies upon matter of law arising upon the face of the proceedings; so that no evidence is required to substantiate or support it; there being no method of reversing an error in the determination of *facts*, but by an attain, or a new trial, to correct the mistakes of the former verdict. A writ of error may be brought for notorious mistakes in the judgment or other parts of the record; as where a man is found guilty of perjury, and receives the judgment of felony, or for other less palpable errors, such as any irregularity, omission, or want of form in the process of outlawry, or proclamations; the want of a proper *addition* to the defendant's name, according to the statute of additions; for not properly naming the sheriff, or other officer of the court, or not duly describing where his county or court was held; for laying an offence committed in the time of the late king, to be done against the peace of the present; and for many other similar causes, which (though allowed out of tenderness to life and liberty) are not much to the credit or advancement of the national justice. These writs of error to reverse judgments in case of misdemeanors are not to be allowed of course, but on sufficient probable cause shewn to the attorney-general; and then they are understood to be grantable of common right, and "ex debito justitiæ." But writs of error to reverse attainders in capital cases are only allowed "ex gratia;" and not without express warrant under the king's sign manual, or at least by the consent of the attorney-general. 1 Vern. 170. 175.

If a writ of error be brought to reverse any judgment of an inferior court of record, where the damages are less than ten pounds; or, if it is brought to reverse the judgment of any superior court after verdict, he that brings the writ, or that is plaintiff in error, must (except in some peculiar cases) find substantial pledges of prosecution, or bail (stat. 3 Jac. I. c. 8. 13 Car. II. c. 2. 16 and 17 Car. II. c. 8. 19 Geo. III. c. 70.): to prevent delays by frivolous pretences to appeal; and for securing payment of costs and damages, which are now payable by the vanquished party in all, except a few particular instances, by virtue of the several statutes here recited. 3 Hen. VII. c. 10. 13 Car. II. c. 2. 8 and 9 W. III. c. 11. 4 and 5 Ann. c. 16.

A writ of error lies from the inferior courts of record in England into the king's bench, and not into the common pleas. (Finch. L. 480. Dyer 250.) Also from the king's bench in Ireland to the king's bench in England. It likewise may be brought from the common pleas at Westminster to the king's bench; and then from the king's bench the cause is removable to the house of lords. From proceedings on the law side of the exchequer a writ of error lies into the court of exchequer chamber, before the lord chancellor, lord treasurer, and the judges of the court of king's bench and common pleas; and from thence it lies to the house of peers. From proceedings in the king's bench in debt, detinue, covenant, account, case, ejectment, or trespass, originally begun there by bill (except when the king is party) it lies to the exchequer chamber, before the justices of the common pleas, and barons of the exchequer; and from thence also to the house of lords (stat. 27 Eliz. c. 8.); but when the proceedings in the king's bench do not first commence therein by bill, but by original writ sued out of chancery, this takes the case out of the general rule laid down by the statute (1 Roll. Rep. 264. 1 Sid. 424. 1 Saund. 346. Carth. 180. Comb. 295.); so that the writ of error then lies, without any intermediate stage of appeal, directly to the house of lords, the dernier resort for the ultimate decision of every civil action. Each court of appeal, in their respective stages, may, upon hearing the matter of law in which the error is assigned, reverse or affirm the judgment of the inferior courts; but none of them are final, save only the house of peers, to whose judicial decisions all other tribunals must therefore submit, and conform their own. Blackit. Com. book iii.

**ERROR, to assign.** See **ASSIGN.**

**ERRORS, Clerk of the.** See **CLERK.**

**ERROR loci**, literally *error of place*, a doctrine of considerable importance in the theory of diseases, taught by the celebrated Boerhaave. It was deemed the principal cause of those obstructions to the circulation of the blood, on which inflammation, in all its varieties, was supposed to depend. "The parts of a fluid," says Boerhaave, "become unable to pass by error of place (per errorem loci), when a corpuscle rushes into the dilated mouth at the basis of a conical canal, and cannot pass through the narrow end of it." (Aphorism 118.) This doctrine is founded upon these three circumstances; the series of particles, of which the blood is composed; the series of progressively diminishing vessels; and the conical form of these vessels: and it is thus explained by the comment of Van Swieten.

The largest particles in the blood are the red globules, which are to be found naturally in the larger vessels only. Now the extremities of the arteries carrying red blood, transmit the red globules singly, according to the observations made with microscopes on the pellucid parts of living animals. The finer parts of the blood are conveyed into the smaller lateral vessels, and the red vein receives the red blood

only. The vessel of the next magnitude receives all the fluids except the red globules, and retaining the larger particles only, (*viz.* the serous globules) transmits the remaining thinner liquids into the still smaller vessels, that arise from the serous artery. This law obtains, then, in all the decreasing series of vessels. The red arteries can receive and transmit all the humours; the serous arteries exclude the red part of the blood, but transmit the serous globules, and every other thinner fluid, and so on. Now, should the diameter of a lateral vessel arising from a larger one be by any means increased, for example, the aperture of a serous artery, which arises from a red one, a red globule might be able to enter its orifice when thus dilated; but as a conical canal always grows narrower, it will shortly stick fast, and be by no means able to pass through its extremity, and consequently will cause an obstruction, as the bulk of the particle to be carried through exceeds the capacity of the transmitting vessel.

This error loci of the fluids was considered as the proximate cause of inflammation by Boerhaave, and his commentator illustrates the dilatation and distention of the lymphatic and serous vessels by the red blood in the case of inflammations of the eye; in which the vessels of the surface of the eye, which are naturally transparent, become red, and visible, sometimes even giving a red colour to the whole of the surface. See Van Swieten, Comment. ad Aph. 118—378, &c.

**ERRUCA**, in *Ancient Geography*, a town of Italy, belonging to the Volsci, according to Diodorus Siculus.

**ERSE**, in *Geography*, a river of Germany, in the circle of Lower Saxony, which runs into the Fuhse; 8 miles S. of Zelle.

**ERSH**, in *Agriculture*, is a term signifying land in the state of stubble after the grain has been taken off. Hence we have pea, bean, and different sorts of grain ershes.

**ERSH-CROP**, is such a crop as is grown after some of these sorts of stubbles have been turned down by the plough.

**ERSTEIN**, in *Geography*, a small town of France, in the department of the Lower Rhine, chief place of a canton in the district of Barr, with a population of 2344 individuals. The canton contains 14 communes and 8991 inhabitants, on a territorial extent of 137½ kilometres.

**ERTA**, a town of Asia, in Parthia.

**ERTHOLM**, a small island, about three leagues from the coast of Schoonem, and half a league from Bornholm. It belongs to the Danes; and till of late was garrisoned only with 50 men: the force has been since augmented to 500. This island may be easily captured and retained by that power, which, during the interval of naval operations in the Baltic, has the superior fleet.

**ERTO DEL FERRO**, a town of Italy, in the kingdom of Naples, and province of Calabria Citra; 10 miles W. of Umbriatico.

**ERTZGEBIRGE**, or rather **ERTZGEBURGE**, (arch-mountainous country,) is the fifth of the seven circles into which that part of the kingdom of Saxony, which is called Saxony Proper, or formerly Electoral Saxony, is divided. As late as the tenth century this whole extensive tract of mountainous country was nothing but an impervious forest, called Miriquido, or Miriquidvi, few spots of which began to be cleared in 1004. It is bounded to the north by the circles of Misnia, or Meissen and Leipzick, and by the principality of Altenburg, to the west by the same principality, the circles of Neustadt and Voigtland, and the dominions of the princes of Reufs; to the south and east by the kingdom of Bohemia. Its principal rivers are the Zschopau, the Flöhe, the Pöhl, the Presnitz, and the Schwartzwasser.

The

The territorial extent of the Ertzgebirge is 121 German square miles, and its population, in 1785, amounted to 405,600 individuals, which gives 3332  $\frac{1}{3}$  inhabitants to the German square mile. It produces corn, potatoes, vegetables of all sorts, and excellent flax, and has several manufactories, but chiefly those which work upon minerals and metals.

The circle of the Ertzgebirge is remarkable for its numerous and valuable mines, which, in 1789, employed 12,867 miners, and, in 1788, yielded in silver only 50,618 marks. The aggregate of all the metals produced the sum of 700,640 dollars. Amalgamation, or application of mercury to extract the silver from the ore, was first introduced in the Saxon mines in the year 1787.

Freyberg is the chief place of the Ertzgebirge, and the first town in Europe for the study of mineralogy. See FREYBERG.

The whole circle of the Ertzgebirge contains 61 towns and 723 villages. It is subdivided into 13 districts, viz. Freyberg, Augustsburg, Chemnitz, Rossien, Frauenstein, Altenberg, Lauterstein, Wolkenstein, Annaberg, Grünhayn, Schwartzberg, Weissenburg, and Zwickau.

ERTZICA, a town of Asia Minor, in Cappadocia, commonly called *Arzingham*.

ERUBRUS, a river of Gaul, thought by M. D'Anville to be the Rouver, which runs into the Moselle, a little below Treves.

ERUCA, in Zoology. See CATERPILLAR.

ERUCA marina griseo fusca. See APHRODITA.

ERUCAGO, in Botany, Tourn. Inst. 232. t. 103, see BUNIAS, spec. 3.

ERUCTATION, BELCHING, the same as ructation.

ERUDITION, denotes learning or knowledge; and chiefly that of history and antiquity, of languages and of books, which is the result of hard study, and extensive reading. The Scaligers were men of deep erudition: the writings of M. Launoy, a priest of the Oratory, are full of erudition.

Mr. Locke says, it is of more use to fill the head with reflections than with points of erudition. If the mind be not just and right, ignorance is better than erudition, which only produces confusion and obscurity. M. Balzac calls a heap of ill chosen erudition the luggage of antiquity.

ERVEDEIRA, in Geography, a town of Portugal, in the province of Estremadura; 12 miles N.N.W. of Leiria.

ERVILIA, in Botany, an ancient name for a kind of vetch or pea. See PISUM OCHRUS, also ERVUM.

ERUPA, in Ancient Geography, a town of Arabia Deserta. Ptolemy.

ERUPTION, in general, a bursting forth, or exclusion of something which was before covered, or concealed.

The eruption of volcanos, or burning mountains, is frequently the effect and issue of earthquakes. See EARTHQUAKE, VOLCANO, &c. For an account of the eruptions of mount *Ætna* and *Vesuvius*, see *ÆTNA* and *VESUVIUS*.

ERUPTION, in Medicine, denotes the appearance of various spots and discolourations of the skin, whether pustules, pimples, rashes, &c.: thus, we speak of an eruption of small-pox, or of measles; and, by a figure of speech, these pustules, rashes, &c. are often denominated eruptions, or cutaneous eruptions.

ERUPTION in Infants. See INFANTS.

ERUPTIVE DISEASES, a term nearly synonymous with CUTANEOUS DISEASES, (which see). Eruptive fevers are those febrile diseases which are accompanied by an eruption of spots or tumours on the skin, by which they are principally characterized: such as small-pox, measles,

chicken-pox, cow-pox, scarlet fever, erysipelas, shingles, &c.

ERVUM, in Botany, an ancient Latin name of unknown derivation. Tare. Linn. Gen. 376. Schreb. 498. Willd. Sp. Pl. v. 3. 1112. Sm. Fl. Brit. 775. Juss. 360. Class and order, *Diaadelphica Decandria*. Nat. Ord. *Papilionacea*, Linn. *Leguminosæ*, Juss.

Gen. Ch. Cal. Perianth of one leaf, tubular, erect, cloven half-way down into five acute segments, all of equal breadth, but the lowermost is rather the longest. Cor. papilionaceous, twice as long as the calyx: standard obovate, nearly entire, ascending, with a broad claw, compressed and keeled at the back; wings two, oblong, obtuse, half heart-shaped, shorter than the standard, with narrow claws; keel as long as the wings, of two conjoined compressed petals, with separate claws. Stam. Filaments in two sets, one composed of nine, the other solitary; anthers roundish, two-lobed, erect. Pist. Germen superior, oblong, compressed, horizontal; style simple, ascending, forming a right angle with the germen, and about half as long; stigma capitate, obtuse, hairy all over. Peric. Legume oblong, obtuse, compressed, rigid, knotty from the prominent seeds, of one cell, and two pointed, spirally-elastic valves. Seeds from two to four, occasionally more, roundish, somewhat compressed.

Ess. Ch. Stigma capitate, hairy all over.

The genus *Ervum* in Linnæus is a heterogeneous assemblage, difficult to be accounted for. *E. Lens*, the species from which his generic character seems to have been principally taken, is most completely a *Cicer*, under which head it should have been described in our eighth volume. *E. soloniense* is not only a true *Vicia*, but the very same plant with *Vicia lathyroides*, Linn. Sp. Pl. 1040. See Engl. Bot. t. 30. *E. monanthos* and *Ervillea*, having the style hairy on the upper side, appear to us to belong to *Lathyrus*. Thus none of the Linnæan *Erva* remain, except our two British species, and these are not only very peculiar in habit, but according to the analogy of the tribe to which they belong, their stigma affords an excellent essential character, not to be found in any other *diadelphous* flower. All this was first explained in the *Flora Britannica*, by the author of the present article, and Willdenow has adopted it in every point, except that he retains the old erroneous character, "calyx deeply five-cleft," in addition to that derived from the stigma, and also makes *E. Ervillea* a *Vicia*. He moreover adopts a supposed new species from Desfontaines, making three in all.

1. *E. tetraspermum*. Smooth-podded Tare. Linn. Sp. Pl. 1039. Curt. Lond. fasc. 1. t. 55. Engl. Bot. t. 1223. Stalks mostly two-flowered. Pods smooth, many-seeded.—A troublesome weed in cultivated land throughout Europe, flowering in June and July. Root annual, fibrous. Stem weak, climbing, branched, square, hairy. Leaflets numerous, alternate, linear-oblong, obtuse, hairy beneath, their common stalk ending in a branched tendril. Flower-stalks axillary, solitary, slender, as long as the leaves without their tendril, each bearing two (sometimes solitary,) little drooping flowers of a pale blue veined with dark purple. Calyx hairy. Pods half an inch long, pendulous, oblong or obovate, smooth. Seeds four; occasionally from five to seven in a variety found in Huntingdonshire and at Algiers, which we have in vain tried to make a distinct species.

2. *E. vicioides*. Vetch-like Tare. Desfont. Atlant. v. 2. 168. t. 198. Willd. Sp. Pl. v. 3. 1112.—Stalks many-flowered. Pods silky, two-seeded. Leaflets obovate, entire. Gathered by Desfontaines in hedges at Algiers. It appears to be very nearly related to the following, from which it

chiefly differs in being rather larger, and in having more rounded and not emarginate leaflets. Nothing however is more variable than the termination of the leaflets in *Vicia* and its allies. The pods are called silky, which is perhaps equally applicable to *E. hirsutum*. All things considered, we much doubt of the permanency of this species, which we, like Willdenow, adopt entirely from the excellent work of Desfontaines. We tolerate, but cannot approve the mixture of Greek and Latin in the name *vicioides*, which if the species should remain, ought to be made *viciaformis*.

3. *E. hirsutum*. Hairy-podded Tare. Linn. Sp. Pl. 1039. Curt. Lond. fasc. 1. t. 54. Engl. Bot. t. 970.—Stalks many-flowered. Pods hairy, two-seeded. Leaflets emarginate.—A pernicious weed in cornfields and pastures throughout Europe. It much resembles the first species, but the stem is usually smoother, the ends of the leaflets more abrupt and notched, the flowers and pods more numerous on each stalk. The most essential difference consists in the shorter, somewhat rhomboid, hairy pods, with only two seeds.—Mr. Curtis observes that he has “in wet seasons seen whole fields of corn overpowered and totally destroyed by this plant, which is stronger and more prolific than *E. tetraspermum*.” He does not, however, suggest any remedy. These weeds are too minute and inconspicuous when young to be eradicated, and when they have fixed their tendrils upon the crop, they can no longer be separated without “rooting up also the wheat with them.” S.

ERVUM *Oriente*. See SOPHORA.

ERVY, in *Geography*, a small town of France, in the department of the Aube, chief place of a canton in the district of Troyes, with a population of 1975 individuals. It is 9 miles S. of St. Florentin, and has some manufactures of linen-cloth. The canton contains 14 communes and 11,199 inhabitants; on a territorial extent of 222½ kilometres.

ERWASH, a river of England, which rises in the county of Nottingham, and almost in its whole course separates that county from Derbyshire, and falls into the Trent, 4 miles S. W. of Nottingham. See EREWASH.

ERWIFE, a town of Germany, in the circle of the Lower Rhine, and duchy of Westphalia; 5 miles S. of Lippstadt.

ERXLEBEN, JOHN CHRISTIAN POLYCARP, in *Biography*, was born in June, 1744, at Quedlingburg, where his father was dean of St. Nicholas's church. He studied medicine at Gottingen, where he took the degree of master of arts in 1765, and shortly after gave lectures on natural history and the veterinary science. Having published his introductory lectures, he undertook, at the expense of the Hanoverian government, a tour through France, Holland, Denmark, and a great part of Germany, in the course of which he acquired much practical knowledge in the veterinary art. On his return he lectured on the several sciences connected with natural history, and natural and experimental philosophy. In 1774, and the following years, he was elected a member of most of the learned societies on the continent. He died in August, 1777, when he had but just attained his thirty-third year. Erxleben published many works which were highly esteemed, among these are “Principles of Natural History;” “Principles of Natural Philosophy;” “An Introduction to the Veterinary Art.” Gen. Biog.

ERYANNOS, in *Ancient Geography*, a river of Asia Minor, in the Troade, which had its source in mount Ida.

ERYBIUM, a town of Greece, in the Doride, situated, according to Diodorus Siculus, at the foot of mount Parosus.

ERYCEIRA, FRANCIS DE MENESES, *Count of*, in *Biography*, born at Lisbon in 1614, was brought up to the use of arms, and obtained some important offices under government; but in the midst of his usual occupations he cultivated literature, and published a number of works, particularly histories of Tangier and Portugal; and the life of John I. king of Portugal.

ERYCEIRA, FRANCIS-XAVIER DE MENESES, was grandson of the preceding, and, like him, united a literary with an active and military life. He was born at Lisbon in 1672, and rose to eminence in the state. He was chosen member of various learned societies. From his ancestor he inherited a well chosen and extensive library, to which he made many great additions. He is said to have been the author of more than a hundred different works, of these, however, but few seem entitled to notice. The best known are, “Memoirs on the Value of the Monies of Portugal,” 4to. 1738; “Reflection on Academical Studies;” “Parallels on Illustrious Men and Women;” and “A Translation of the Henriade.” He died in the year 1743. Nouv. Dict. Hist.

ERYCINA, in *Mythology*, a surname given to Venus, from Erix, a mountain in Sicily, where she had a temple. Venus Erycina had also a temple at Rome, which was deemed very ancient even in the time of Thucydides. See ERIX.

ERYMANTHUS, in *Ancient Geography*, a mountain or forest of the Peloponnesus, in Arcadia, E. of a river of the same name, which had its source towards the north, on the confines of the Elide and of Arcadia, in mount Lampie. The wood of Erymanthus was full of boars, which made great desolation in the country. Hercules was employed to give chase to them, which he did with such success, that he slew with his own hands the largest of them. See HERCULES.—Also, a town of the Peloponnesus, in Arcadia, called *Phigia* and *Psophis*, according to Pausanias.

ERYMI, a people of Scythia, on this side of the Imaus. Ptolemy.

ERYMNÆ, a town of Asia Minor, in Lycia. Steph. Byz.—Also, a town of Greece, in Thessaly; placed by Pliny in Magnesia.

ERYNGIUM, in *Botany*, *εργυγιον* of Dioscorides, the derivation of which is unknown. Eryngo or Sea Holly. Linn. Gen. 127. Schreb. 177. Willd. Sp. Pl. v. 1. 1356. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 288. Juss. 226. Gærtn. t. 20. Class and order, *Pentandria Digynia*. Nat. Ord. *Umbellifera*.

Gen. Ch. *Common Receptacle* conical. *Flowers* all fertile, sessile, with scales between them. *Involucrum* of the whole receptacle of many leaves, flat, spreading beyond the flowers. *Cal.* Perianth superior, of five upright, acute leaves, sessile on the germen, shorter than the corolla. *Cor.* in the aggregate uniform, roundish. Petals five, equal, oblong, with a linear longitudinal striature, their points bent in, so as nearly to reach the base. *Stam.* Filaments five, capillary, straight, projecting far above the corolla; anthers oblong, versatile. *Pist.* Germen inferior, bristly; styles two, thread-shaped, a little spreading, somewhat shorter than the filaments; stigmas simple. *Peric.* Fruit ovate, separable perpendicularly into two parts. *Seeds* oblong, cylindrical; in some species remaining shut up in the crust of the pericarp, in others deciduous from it.

Ess. Ch. *Involucrum* of many leaves. *Flowers* in little dense heads. *Common receptacle* conical, scaly. *Seeds* bristly.

A most singular and very natural genus, having the habit and aspect of a thistle, the herbage rigid, thorny, either

either more or less tinged with vivid blue, or pallid and whitish; while the fructification is exactly that of an umbelliferous plant, though the inflorescence is capitate. Willdenow has eleven species, but they and their synonyms require a thorough investigation. Two are natives of Britain, viz. *E. maritimum*, Engl. Bot. t. 718, (in which plate we are sorry to remark that the petals are drawn reflexed instead of inflexed, an error that now escaped us.)—This is frequent on sandy sea shores throughout Europe, flowering in July and August. The long creeping perennial roots are aromatic and somewhat acrid; they are esteemed stimulant and restorative, and are sometimes sold candied. The herbage is glaucous variegated with a permanent blue. Leaves rounded, plaited, lobed, with spinous teeth. Flowers blue, in dense terminal heads, encompassed with a large leafy involucre. Scales of the receptacle three-cleft. The other British species is *E. campestris*, Engl. Bot. t. 57, found very rarely in England, though common on the continent. Its leaves are much more narrowly divided than the first, and pinnatifid. Flowers greenish-white, with narrow involucre leaves and undivided scales. This appears to be the true *eryngium* of Dioscorides.

Among the exotic kinds *E. amethystinum*, Linn. Sp. Pl. 337, a native of Styria; *E. alpinum*, *ibid.* Curt. Mag. t. 922, from the Swiss alps; and *E. planum*, Jacq. Austr. t. 391, are all hardy perennials, frequently cultivated for ornament. The *alpinum* is indeed peculiarly handsome, on account of its many-leaved, finely divided, blue involucre.

The following five species are not in Willdenow.

*E. cyanum*. Sm. Prod. Fl. Græc. Sibth. v. 1. 175. Fl. Græc. v. 3. t. 258. unpublished. "Radical leaves in five deep pinnatifid segments. Stem much branched and divaricated. Involucre of about five leaves."—Common in Greece and the islands of the Archipelago. The root is perennial. Stem 12 or 18 inches high, of a fine blue, as well as the involucre and foliage, many-flowered and divaricated. Leaves small, in linear, narrow, pinnatifid segments. Heads of flowers small, blue, with prominent, conspicuous, white anthers. This most resembles *E. triquetrum*, Vahl. Symb. v. 2. 46, in habit, but the flowers and involucre are very different.

*E. multifidum*, *ibid.* Fl. Græc. v. 3. t. 259.—"Leaves doubly pinnatifid, somewhat lyrate; radiated at the extremity. Stem corymbose. Involucre pinnatifid."—Gathered by Dr. Sibthorp in the Morea. Taller than the last, with a bright blue stem and flowers. The finely pinnatifid leaves give it the aspect of an *Echinops*. This is presumed to be *Eryngium creticum erectum, folio multifido, caule et ramis amethystinis*; Tourn. Cor. 23.

*E. parviflorum*, *ibid.* (*E. foliis laciniatis, capitulis florum exiguis et dense congestis*; Tourn. Cor. 23.) "Leaves bipinnatifid. Stem corymbose. Involucre three-cleft or simple, four times as long as the head." Of this no figure is extant, nor is it known where Dr. Sibthorp gathered the specimens found in his herbarium. The root is perennial. Herb whitish. Stem densely clothed with leaves, and bearing numerous flowers at the summit. Leaves twice or thrice pinnatifid, their segments narrow and divaricated. Heads of flowers very small, with large involucre, generally of five leaves, which are either undivided or three-cleft.

*E. purpuratum*. Leaves all pinnatifid, their lower part fringed with capillary teeth. Stem nearly simple, with few flowers. Involucre of about seven undivided leaves.—Gathered near Tangier by the late M. Broussonet and the Abbé Durand, who severally sent specimens to Dr. Smith. Root perennial. Stems a span high, round, furrowed, leafy,

scarcely branched, but bearing about three dark-blue heads of flowers, with very spinous calyces. Leaves all nearly alike, pinnatifid, with decurrent, sometimes lobed, segments; their lower part clasping the stem, pectinated, fringed with five long capillary teeth. Great part of the stem, and the upper side of each leaf of the involucre, are tinged with a rich deep blueish purple, hardly equalled in any other of the genus.

*E. carthamoides*. Leaves oblong, toothed, undivided, heart-shaped and clasping the stem at their base. Stem nearly simple, with few flowers. Involucre of several ovate leaves. Gathered by M. Broussonet in the neighbourhood of Algiers, flowering in June. Stem a foot high, strong, round, leafy, sometimes purplish, simple, except at the summit, where it bears from three to five large heads of blueish flowers, whose involucre consists of several large, ovate, purplish, spinous-toothed leaves, much resembling those of a *Carthamus*. The radical and stem-leaves are all simple, oblong, wavy, with large spinous teeth, veiny and pale-green.

ERYNGO, in the *Materia Medica*. The root of eryngium is attenuant and deobstruent, and is therefore esteemed a good hepatic, uterine, and nephritic. Its whole virtue, it is to be observed, consists in the external or cortical part. Their virtues, however, appear to be but weak; and they are now scarcely otherwise used than as made into a sweetmeat.

The London college directs it to be candied in the following manner: boil the roots till the rind will easily peel off; when peeled, slice them through the middle, and the pith being taken out, wash them three or four times in cold water; then for every pound of roots thus prepared, take two pounds of double-refined sugar; dissolve the sugar in water, set it on a fire, and as soon as it begins to boil, put in the roots, and continue the boiling till they become soft.

These candied roots are an ingredient in artificial asses milk, which is thus made: take of candied eryngo root one ounce, pearl barley half an ounce, liquorice root three drams; boil them in two pints of water to one pint, to which add a pint of new milk from the cow; boil them gently together, then strain the liquor for use, of which half a pint should be drunk three times a day.

ERYNNIS, *q. d. epis vs, contentio mentis*, or because, as Paulianus remarks, *ἐπύνην* signifies to fall into a fury, or *Furious*, a name given to Ceres by the Sicilians.

ERYSIBE, in *Botany*, *ερυσίβη, rust, or the mildew of corn*, from its rusty panicle. Roxb. Pl. Coromand. v. 2. 31. Class and order, *Pentandria Monogynia*. Nat. Ord. *Sapoteæ*, Juss.

Gen. Ch. Cal. Perianth in five deep, roundish, concave, permanent segments. Cor. of one petal, salver-shaped, the length of the calyx; tube cylindrical, pervious; limb the length of the tube, in 10 roundish segments, spreading. Stam. Filaments five, very short, inserted into the lower part of the tube; anthers erect, ovate, shorter than the tube. Pist. Germen superior, ovate; style none; stigma five-lobed. Peric. Berry oval, of one cell. Seed solitary, large.

Eff. Ch. Corolla salver-shaped; limb in ten equal segments. Style none. Stigma five-cleft. Berry superior, with one seed.

*E. paniculata*. Roxb. Coromand. t. 159. The only known species, a native of the mountain forests of India, from whence Dr. Roxburgh sent us specimens in 1789. A very large climbing shrub. Branches alternate, leafy, round, clothed when young with copious rusty down. Leaves alternate, three- or four inches long, spreading and

defflexed, elliptic-oblong, pointed, entire, velvety; smooth and shining above; paler and opaque beneath. *Footstalks* half an inch long, angular, rusty. *Stipules* none. *Panicles* many-flowered, terminal, erect, much branched, about a span long, their stalks, small oblong scattered bractæas, and the calyx, all densely clothed with rusty down. Tube of the *corolla* greenish; limb yellow, about three lines in diameter. *Berry* the size of a small cherry, black, pulpy, containing one large seed.

Of the uses or qualities of this plant or its fruit we have no account. From its botanical affinity to *Chrysophyllum*, *Achras*, &c. it may certainly be eaten with safety. The flowers are not inelegant.

ERYSIMA, in *Ancient Geography*, a town of Asia, in Cappadocia.

ERYSIMUM, in *Botany*, ερυσιμον of Theophrastus and Dioscorides, about the etymology of which there is much controversy among the learned, but, as often happens in such controversies, nothing satisfactory. Hedge-mustard. Linn. Gen. 339. Schreb. 442. Willd. Sp. Pl. v. 3. 509. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 706. Juss. 239. Tournef. t. 111. Gærtn. t. 143. Class and order, *Tetradynamia Siliquosa*. Nat. Ord. *Siliquosa*, Linn. *Crucifera*, Juss.

Gen. Ch. *Cal.* Perianth of four ovate-oblong, coloured, parallel, cohering, deciduous leaves. *Cor.* cruciform, of four oblong, flat, very obtuse petals, whose claws are the length of the calyx and erect. Nectary a gland betwixt each of the shorter filaments and the germen. *Stam.* Filaments six, the length of the calyx; of which two opposite ones are shorter than the rest; anthers simple. *Pistl.* Germen superior, linear, square, the length of the stamens; style very short; stigma small, capitate, permanent. *Peric.* Pod long, linear, straight, exactly square, of two cells and two valves. *Seeds* numerous, small, roundish.

Eff. Ch. Pod straight, columnar, exactly square. Calyx-leaves cohering. Stigma capitate.

Willdenow has 14 species, of which five are British.

1. *E. officinale*. Linn. Sp. Pl. 922. Curt. Lond. fasc. 5. t. 50. Engl. Bot. t. 735. "Pods close-pressed to the main stalk. Leaves runcinate." Common in waste ground and about hedges. This is usually taken for the ερυσιμον of Dioscorides, whose description, more full than usual with that writer, is very applicable to it. Dr. Sibthorp, however, decidedly considered *Sisymbrium polyceratium* as the plant Dioscorides meant, and this, perhaps, will be found to accord still better with his description, which compares the horn-like pods to fœnugreek. See its figure in Matthioli, Ed. Valgr. fol. v. 1. 524. The ερυσιμον of Theophrastus is supposed to be a still different plant, as he reckons it among the various kinds of grain.

In this and similar cases, therefore, though the Linnæan generic name is adopted from ancient writers, it does not follow that their plant is of the same genus, which matter is frequently impossible to be ascertained. It is sufficient that such names are established by common consent amongst systematical botanists, from whom they acquire a new stamp of authority; nor ought they to be changed, whatever new light may be thrown upon them by future commentators. We study by the arrangements of Linnæus or Jussieu, not by those of Theophrastus or Dioscorides. It is only in case any species requires to be separated from an established genus, that we are glad to recur to its ancient appellation for a generic name; as in the cases of *Cyamus*, Sm. Exot. Bot. v. 1. 59. t. 31, 32 (see *CYAMUS*); and *Nuphar*, Prod. Fl. Græc. v. 1. 361.

2. *E. Barbara*. Linn. Sp. Pl. 922. Engl. Bot. t. 443.

"Lower leaves lyrate; their terminal lobe rounded: upper ones obovate, toothed."—Common in waste ground, either dry or wet, flowering most in the spring. Its numerous flowers of a full yellow, often seen double in gardens, and its dark shining broad leaves easily distinguish it. The whole plant has a nauseous, bitter, slimy flavour.

3. *E. praecox*. Sm. Fl. Brit. 707. Engl. Bot. t. 1129. "Lower leaves lyrate: upper ones pinnatifid, their segments linear, oblong, and entire."—Found in Devonshire by the Rev. Dr. Beeke. The narrow lobes of the stem-leaves, smaller flowers, and much longer pods, distinguish this from the last, with which we believe Linnæus confounded it. The distinction is highly important, as we are convinced the present is the very same with the American Cress, as it is called, or rather Winter Cress, of the gardens, an agreeable and wholesome pungent herb for fallads, &c.

4. *E. Alliaria*. Linn. Sp. Pl. 922. Curt. Lond. fasc. 2. t. 48. Engl. Bot. t. 796. "Leaves heart-shaped."—Common under hedges in the spring, and knowna by its broad toothed leaves, white flowers, and strong scent of garlick when bruised.

5. *E. cheiranthoides*. Linn. Sp. Pl. 923. Engl. Bot. t. 942. Jacq. Austr. t. 23.—"Leaves lanceolate, slightly toothed. Pods erect. Flower-stalks when in fruit spreading."—Not rare in Oser-grounds, Turnip-fields, and other cultivated ground, where the soil is gravelly or sandy, flowering in July. This resembles the yellow stock or wall-flower in habit and leaves, but the small flowers and square pods at once distinguish it.

The exotic species are not quite so well ascertained as ours. Ehrhart and Roth have taken pains to elucidate them, and the result is given by Willdenow. We know not that any of them is worthy of the attention of the cultivator except for botanical curiosity.—They are all either annual or biennial, perfectly hardy in our climate, and bear narrow lanceolate leaves, with small yellow flowers. As weeds their copious seeds render them rather troublesome.

ERYSIPELAS, from ερυσσ, to draw, and πηλας, near, from the disposition of the affection to draw the adjacent parts into the same state; or from ερυθρος, red, and μελας, black, a dark red.) The generality of surgical authors have considered erysipelas as a species of inflammation, and every reflection induces us to entertain the same opinion, notwithstanding the opposite sentiment of one of the lecturers on surgery in this metropolis. The immortal Celsus has observed: "notæ verò inflammationis sunt quatuor; rubor, et tumor, cum calore et dolore," lib. 3. cap. 10. According to this definition, erysipelas is certainly an inflammation, although the degree of swelling is not so great, nor the pain exactly of the same kind, as in cases of phlegmon, or common inflammation.

With many distinguished surgical authors, we regard erysipelas as a particular kind of inflammation, most frequently affecting the small vessels on the surface of the body. It is, as Mr. Hunter describes, more commonly a cutaneous inflammation, than one situated in deeper parts; although it is probable, that, in some constitutions, every inflammation, wherever it exists, will be of this kind. However, there can be no doubt of the fact laid down by this accurate observer, viz. that the skin appears to be the most susceptible of erysipelas, because this affection will spread over a prodigious extent of the surface of the body, while (at least, in common instances) the cellular membrane underneath remains free from disorder. (See Hunter on Inflammation, p. 270.)

Mr. Hunter taught surgeons, that one of the uses of the adhesions,

## ERYSIPELAS.

adhesions, which form in cases of common inflammation, is to circumscribe and bound the matter, in the event of suppuration taking place. Now, in erysipelas, the extravasation in the place affected is not so considerable as in phlegmon, nor is it of that kind, which produces adhesions among the inflamed parts. Indeed, since erysipelas seldom ends in suppuration, such adhesions, according to Mr. Hunter's view of the subject, would in general be unnecessary. Perhaps, also, the circumstance of there being no adhesions in erysipelatous cases, may account for the terrible diffusion of mischief, which always happens, when abscesses do occasionally take place. Then, we know, that the matter makes its way extensively through the cellular substance, in every direction under the skin, under fascia, and between the muscles, producing, wherever it goes, what has been often named a gangrenous suppuration. When erysipelas is of an unmixed kind, it has not the dark red colour which common inflammations have, but a lighter red, with a yellow tinge, which is particularly observable towards the termination of the disorder. The swelling which occurs is unattended with any remarkable induration, and forms a very inconsiderable prominence. The skin of the inflamed part has a shining appearance, and, on being touched with the finger, turns white at the spot where the pressure is made; but the bright red colour immediately afterwards returns. The pain is usually of a burning, shooting description, and the patient frequently complains of a sort of itching, which is found to be particularly annoying. The swelling, which happens in cases of erysipelas, is not only not so hard and elevated as that which arises in examples of phlegmonous inflammation, it is at the same time not so clearly circumscribed.

Another remarkable feature of erysipelas, is the manner in which this inflammation often changes its situation, by getting well on one side, while it is spreading in some other direction. The great celerity with which the affection spreads, and the large surface which it in a very little while covers, may also be set down among its most striking peculiarities.

When the affection is intimately dependent on the state of the constitution, we very often see all the local symptoms recede in one place, and the disease make its attack in some other part of the body. Such instances are not unfrequently mentioned by writers as *metastases*, just as if it were a real fact, that, when the erysipelatous symptoms get well on one leg, and the other leg becomes affected in a similar way, these events happen, in consequence of the first identical disease actually moving from one limb to the other. From this absurd doctrine originates all the cant about the danger of using such applications as are likely to repel the inflammation. The truth is, that the second attack of the erysipelas is not at all connected with the termination of the first; but arises from some different, and probably inexplicable cause, just as encysted tumours will often form, one after another, in various parts of the body, as regularly as they are cut out. In this latter instance, no one is absurd enough even to suspect that the growth of one tumour is the effect of a previous one being cured.

In true erysipelas, there is no throbbing of the part affected, as in cases of phlegmon; and when erysipelatous inflammation runs along the skin, the affection has a determinate edge, and does not lose itself gradually and insensibly in the surrounding parts, as common inflammation does.

The alteration which the skin undergoes in erysipelas consists in its feeling at the part affected less pliable than in the natural state, and a little thickened.

Such are the ordinary local symptoms of erysipelas.

They are subject, however, to some variety, depending on the mildness or violence of the attack, and on the circumstance of the disorder being either simple, or complicated with another affection; for instance, œdema, phlegmon, &c.

With respect to violence, erysipelas may be very properly divided into three degrees. In the first, or mildest form of the complaint, the erysipelas makes its appearance, without any preceding illness, or with only a slight indisposition of short duration, and consisting of lassitude, disturbed sleep, loss of appetite, &c. These complaints very soon go off, when the erysipelas comes out, which happens in about a couple of days. For two days more the local symptoms remain the same, and then the erysipelas turns pale and yellow, gradually disappearing altogether, with a detachment of the cuticle. During the whole course of the disorder there is no fever of any consequence; but a little while before the redness occurs the pulse is sometimes rather disturbed.

In the second, or more severe degree of the disorder, the patient is troubled, about two days before the erysipelas makes its appearance, with an unusual prostration of strength, heaviness in all his limbs, head-ach, loss of appetite, nausea, and even actual vomiting, complaints in the stomach, &c. Besides these inconveniences, the patient is affected with a fever, and all its usual symptoms. After a couple of days, commonly on the third day from the commencement of all indisposition, the erysipelas comes out, attended with a gentle sweat, and a moderate increase in the secretion of urine, after which circumstances the fever, with all its attendant symptoms, goes off. The rest of the progress of the case is similar to what we have related, as happening in the first, or mildest attack of erysipelas.

In the third, or most violent degree of the disorder, particularly in those cases in which erysipelas makes its attack on the face, the patient is affected with severe febrile symptoms, head-ach, loss of sleep, delirium, sickness, &c. These complaints do not diminish, as in the milder cases of erysipelas, when the local redness, heat, &c. take place on the third day; but continue with unabated vehemence, until the erysipelas itself subsides. The last desirable event commonly happens, according to Richter, on the eleventh day, accompanied with an increase in the secretions from the skin and kidneys.

The most dangerous cases of erysipelas are those in which the face is affected. Of this form of the disorder, the celebrated Cullen has left us a matchless description, which we think is highly deserving of insertion in this Cyclopædia. The erysipelas of the face, (says this interesting author,) comes on with a cold shivering, and other symptoms of pyrexia. The hot stage of this is frequently attended with a confusion of head and some degree of delirium; and almost always with drowsiness, or perhaps coma. The pulse is always frequent, and commonly full and hard.

When these symptoms have continued for one, two, or at most three days, there appears on some part of the face a redness, such as that of erythema. This redness at first is of no great extent; but, gradually spreads from the part it first occupied, to other parts of the face, commonly till it has affected the whole; and frequently from the face it spreads over the hairy scalp, or descends on some part of the neck. As the redness spreads it commonly disappears, or, at least decreases in the parts it had before occupied. All the parts upon which the redness appears are at the same time affected with some swelling, which continues for some time after the redness has abated. The whole face becomes considerably turgid; and the eye-lids are often so much swelled, as entirely to shut up the eyes.

## ERYSIPELAS.

To continue Dr. Cullen's account: when the redness and swelling have proceeded for some time, there commonly arise, sooner or later, blisters of a larger or smaller size on several parts of the face; these contain a thin yellowish, or almost a colourless liquor, which sooner or later runs out. The surface of the skin in the blistered places sometimes becomes livid and blackish, but this livor seldom goes deeper than the surface, or discovers any degree of gangrene affecting the skin. On the parts of the face not affected with blisters the cuticle suffers, towards the end of the disease, a considerable desquamation.

Sometimes the tumours of the eye-lids end in a supuration.

The inflammation coming upon the face does not produce any remission of the fever which had before prevailed; and sometimes the fever increases with the increasing and spreading inflammation.

The inflammation usually continues for eight or ten days; and, for the same time, the fever and symptoms attending it also continue.

In the progress of the inflammation, the delirium and coma attending it sometimes go on increasing, and the patient dies apoplectic, on the seventh, ninth, or eleventh day of the disease. In such cases, it has been commonly supposed that the disease is translated from the external to the internal parts. But, Dr. Cullen observes, that he never met with any instance in which it did not appear to him, that the affection of the brain was merely a communication of the external affection, as this continued increasing at the same time with the internal.

When the fatal event does not take place, the inflammation, after having affected a part, commonly the whole of the face, and, perhaps, the other external parts of the head, ceases. With the inflammation the fever also ceases; and, (says Cullen,) without any evident crisis, the patient returns to his ordinary state of health.

The same distinguished writer represents the disease as being not commonly contagious; but he conceived it possible that it might sometimes be communicated from one person to another; and, he adds, that persons who have once laboured under the disorder are liable to returns of it.

According to Cullen, the event of the disease may be foreseen from the state of the symptoms which denote more or less affection of the brain. If neither delirium nor coma comes on, the disease is seldom attended with any danger; but when these symptoms appear early in the disease, and are in a considerable degree, the utmost danger is to be apprehended.

We have already remarked that, in cases of erysipelas, suppuration does not frequently happen; but that when it does, owing to the matter not being confined by the adhesive inflammation, very bad consequences follow. Wherever the matter spreads, it occasions under the skin an extensive sloughing of the fasciæ, tendons, and cellular substance, all which kind of mischief may take place; while the skin itself, which is very vascular and highly organized, remains unimpaired in its texture. This combination of suppuration and mortification is more likely to happen when the erysipelatous inflammation extends to a greater depth than common, so as to affect the cellular membrane. In this state, as Mr. Hunter has well described, air, matter, and sloughs, are all produced together under the skin, and, on handling the part, a strange feel is communicated, neither like that of a fluctuation, or a crepitation. Mr. John Pearson very whimsically, we will not say unaptly, compares the sensation with that excited by a quagmire or morass. Frequently, the practitioner may observe in some opening, made either by ulcera-

tion or the lancet, a small black sloughy point, and, on taking hold of it with a pair of forceps, and drawing it out, he finds, to his great surprise, that a whole mortified tendon, of considerable length, follows his instrument.

Erysipelas is to be met with more frequently in summer than winter, and more commonly in hospitals than other places. Wounds of the head, oftener than any other kind of accident, give rise to the disorder.

Erysipelas has sometimes been observed on the skin of new-born infants. Several instances of this kind are mentioned in the Medical Communications, as having occurred in the British Lying-in-Hospital. In one of these examples, the child was born with its whole face swelled and inflamed, the left side being affected with a true erysipelas. There was also an inflammation on the legs, feet, and left hand. On each tibia, there appeared an oblong slough, of a dark brown colour, almost livid; the one on the left leg was exceedingly large. The cure was attempted by employing embrocations, emollient poultices, and fomentations, and applying camphorated spirit of wine. This child appears to have swallowed the decoction of bark with great ease, as it took four ounces of it every day from the very time of birth. In three days the swelling of the face and other parts had considerably subsided; but, on the third day, a vesication began to form on the left cheek, and another just above the eye-brow, on the same side. These vesications increased in number and size, especially on the legs, where they extended over the whole limb. Some confectio cardiaca was added to the decoction of bark, and pledgets, dipped in oil of turpentine, were put on all the parts affected, previously to the application of the poultice. The vesications began to break on the sixth day, and a sanies to issue from them; yellow sloughs also now made their appearance in different parts. The child seemed much debilitated, and, for the last three or four days, had taken eight ounces of the decoction of bark, with one dram of the confectio cardiaca every twenty-four hours. The pledgets, applied to the sores, were dipped in a digestive ointment, with oil of turpentine, and some cataplasm e cymino. Under this mode of treatment, the sloughs were soon detached, and the child recovered, though not without the loss of the little finger, two joints of the ring finger, and one of the middle one.

The distemper, which we have just been describing, for some time proved extremely fatal, none of the infants recovering who were attacked. However, bark is stated to have acted quite as a specific remedy for the disease, as soon as it was tried, and almost all the children are said to have got well who took this medicine. Mortification always took place in such subjects as died; and the danger was regularly observed to be the greatest in the instances in which the genitals were the parts first attacked. The disease was also noticed to affect the children of weakly women, and of such as were addicted to drinking spirits.

To return, however, to our account of the common forms of erysipelas, we have to apprise the reader, that the term "St. Anthony's fire," which is so frequently mentioned by all sorts of persons, is strictly applied by medical writers and practitioners to that species of the affection in which vesicles arise upon the surface of the skin; while other instances, not accompanied with vesications, are named *simple erysipelas*.

The division of the subject, however, cannot be properly comprehended under these two varieties; and the generality of authors have found it necessary to observe other distinctions.

## ERYSIPELAS.

Mr. Pearson, in his Principles of Surgery, has noticed the following species of the complaint :

1. The acute erysipelas.
2. The œdematose erysipelas.
3. The malignant, or gangrenous erysipelas.

Each of these species may be an idiopathic, or symptomatic disease.

Mr. Pearson remarks, that the acute erysipelas is most commonly seen in those of a sanguine and choleric temperament ; it is generally sudden in its attack, and usually affects the face. Febrile symptoms are often present immediately after the accession of the disease ; but they gradually diminish as the erysipelas becomes more distinctly formed. Considerable heat, and great uneasiness, take place in the part affected ; the skin is also of a brighter scarlet colour than in the other species. If pustules appear, they are distinct ; but sometimes there are no vesications on the surface.

Suppuration very rarely occurs in this kind of erysipelas, and the violence of the disease commonly subsides in three or four days ; the part then grows yellowish, and throws off furfuraceous scales. The disease terminates about the tenth day. A tenderness of the hairy scalp will often continue for a considerable time after the disease has disappeared.

The acute erysipelas, as we have already observed, is sometimes an idiopathic affection ; frequently it is symptomatic, or, in other words, the consequence of a wound, especially one of the head. Persons who have once been attacked with the acute erysipelas, in a spontaneous manner, are particularly liable to suffer again from future attacks of the same disorder.

Mr. Pearson states, that the œdematose erysipelas is not, in general, so sudden in its attack, nor so severe on its accession, as the acute erysipelas. The disease increases gradually, is more diffused, and is attended with less burning pain. If febrile symptoms should arise, they never run high, nor are they of long duration ; most commonly the strength is depressed, attended with a soft, frequent, perhaps, irregular pulse. In this species of erysipelas no constitutional relief is derived from the appearance of the local affection : on the contrary, the danger increases with the progress of the external disease.

When the face is the seat of the œdematose erysipelas the whole countenance has a bloated appearance. The red colour of the skin is mingled with yellow or brown, and the complaint is attended with shiverings, vomiting, and more or less disturbance of the functions of the brain. Mr. Pearson further remarks, that the vesications are often small and numerous, and, that when they have been exposed for a few days to the air, the countenance becomes covered with a dark-coloured crust, very much resembling the appearance which arises in the confluent small-pox. Though the face is very much swelled, it is not firm to the touch, and easily yields to pressure.

The œdematose erysipelas is deemed highly dangerous. Patients often die, in a delirious or comatose state, about the seventh day, sometimes a little later.

It is common to see many people afflicted with this species of erysipelas about the same time. Mr. Pearson informs us, that, in hospitals, he has seen several persons successively attacked with the complaint in the same ward. Some conjectures have been entertained of the disorder being contagious.

All ages and constitutions may be affected with the œdematose erysipelas. However, subjects weakened by age, or intemperance, are most frequently attacked. Dropsical

patients, children, and new-born infants, are also seen affected with the complaint.

According to Mr. Pearson, the œdematose erysipelas, when symptomatic, is much less dangerous than when idiopathic ; but, says this author, whenever the face is considerably affected, the disease is always to be regarded as a serious one, whatever be the remote cause. On the limbs it is seldom dangerous, or very afflicting, unless treated in an improper way. Mr. Pearson mentions his having seen the œdematose erysipelas make its first appearance upon the face, and, by a gradual and regular progression, proceed downward to the extremities, successively appearing upon an inferior portion of the body, as it disappeared from a superior part. Each renewed accession of the complaint was less and less severe, as it receded to a greater distance from the part that was primarily affected.

The malignant, or gangrenous erysipelas, makes its first appearance somewhat like the œdematose form of the disorder. Its progress, however, is much quicker. Phlyctenæ, with a livid base, soon occur on the skin, together with gangrenous symptoms. The disease, at a very early period, becomes attended with a state of the constitution, resembling that which exists in putrid fevers.

The gangrenous erysipelas mostly occurs on the face, neck, breast, and shoulders : the danger of the disease depends very much on the state of the constitution.

When an erysipelatos inflammation, particularly one of the legs has been cured, a degree of œdema will frequently continue about the lower part of the limb for some time afterwards.

Erysipelatos inflammation differs from phlegmon in the following respects. The swelling is less prominent ; and is never distinctly circumscribed. The skin often has the appearance of being scorched, or burnt. The redness is quite circumscribed, has a very determinate edge, is frequently tinged with yellow, and, on being touched with the end of the finger, a white spot is produced for a short time in the place where the pressure was made. The pain is not of the lancinating, throbbing kind, which attends phlegmonous inflammation ; but is such as causes a sensation of a great heat and burning in the part, together with a violent degree of itching. The part affected does not present the feel of, what surgeons understand by, tension ; but only seems to the touch as if the skin were a little thickened. Except in the acute erysipelas, there is no hardness of the pulse, as in cases of phlegmon, and instead of being attended, as the latter affection, with rather an increase of strength, erysipelas is almost always accompanied with more or less debility.

With respect to the causes of erysipelas our knowledge is very imperfect, and every observation on this subject must be received with doubt. We do not mean to state, that the remote causes are not very often sufficiently obvious. We frequently have occasion to remark, in the practice of surgery, that certain punctured wounds, and injuries of the external parts of the head give rise to erysipelas. Indeed, we may state, as a general remark, that the same class of irritations, termed *remote causes*, which in one constitution would occasion phlegmonous inflammation, in another would excite erysipelas. What is far more difficult of investigation, is the cause why erysipelas should take place rather than common inflammation ; in other words, the exact particularity, to which the origin of erysipelatos inflammation is to be ascribed, is involved in much more obscurity. Sometimes even the remote cause cannot be discovered, the affection having the appearance of originating in a spontaneous manner.

## ERYSIPELAS.

It was one of the ancient doctrines, established by Galen, and maintained down to the present time, that what is understood by a bilious habit is particularly subject to erysipelatous inflammation. Many parts of the writings of the celebrated Pott, the experienced Richter, and other noted modern writers, evince their belief in this opinion.

Weak and irritable constitutions appear to us to be most subject to erysipelas; while strong, plethoric persons most frequently undergo common phlegmonous inflammation. We think, that there is every reason to believe, that, in general, erysipelas is intimately dependant on the state of the constitution, or on some peculiarity of temperament. This opinion is somewhat confirmed by the fact, that while persons, who lead drunken, intemperate lives, are particularly often afflicted with erysipelatous inflammation, in consequence of local injuries, other people, who lead more regular lives, generally have phlegmonous inflammation after similar injuries.

It must be admitted, however, that erysipelas occasionally makes its appearance in constitutions with which we can find no evident fault. Indeed, Hunter seems to have considerable reason for his inference, that the affection may, in some instances, be altogether independent of constitutional causes, since it is the common course of the disease to be actually getting well on one side as fast as it is spreading on another.

If we can sometimes assign particular circumstances, which operate as causes conducive to erysipelas, it is all that we can hope to do. To trace the proximate cause in every example which presents itself, is far beyond our pretensions; neither do we believe that it is to be done by the powers of human research. We might adopt the language of Cullen, and talk of erysipelas depending "on a matter generated within the body, and thrown out, in consequence of fever, upon the surface of the body." We might also join Mr. Pearson in representing erysipelas as being sometimes the "critical termination of another disease, such as obstructed menstruation, quartan ague, suppressed suppuration, spasmodic and convulsive diseases." However, we should shew just as much devotion for truth, were we to offer any other wild, vague suppositions, unsupported by rational evidence.

Less aspiring in our attempts, we shall only aim at pointing out circumstances which seem to act as causes, conducive to the disorder, in some instances. If many women of temperate lives, and young children, are occasionally affected with erysipelas, as they undoubtedly are, the fact only proves, that there are other causes besides intemperance which may be concerned in giving rise to the complaint. The sources of the disease must, we believe, on some occasions, be regarded as among the mysterious and inaccessible secrets of nature. When drunkenness and other kinds of intemperance are assigned as causes conducive to erysipelas, it is not meant that they are exclusively so. There are, probably, hundreds of other causes in existence, though we may not be able to detect them.

With regard to women of temperate regular lives, and to children being occasionally affected with erysipelatous inflammation, the fact cannot be called in question. But, still, no experienced man will contend that such subjects are attacked with erysipelas, on meeting with local injuries, half so frequently as persons with constitutions impaired by any kind of intemperance, habits, or modes of life.

Richter and some other writers, have described erysipelas as depending very much on a suppressed state of the perspiration; but we are inclined to think that they have ascribed the importance of a cause to a mere effect of the fever, with which erysipelas is connected.

*Treatment of the acute, or phlegmonous erysipelas.*—This species of the disease being commonly attended with a full, and frequently a hard pulse; the blood drawn shewing upon its surface the buffy coat to be seen in all inflammatory complaints; and lastly, the swelling of the eyelids, frequently ending in suppuration; there can be no doubt, that the affection should be treated very much in the same manner as phlegmonous inflammation. Blood-letting, cooling purgatives, and every part of the antiphlogistic regimen, are advised by Cullen, who affirms, that his experience had confirmed the fitness of this method of cure.

The evacuations of blood-letting and purging are to be employed, more or less, according to the urgency of the symptoms, particularly the febrile ones, and those which mark an affection of the brain.

Although Mr. Pearson mentions general and topical bleeding as being indicated in the treatment of the acute erysipelas, yet he observes, that cases very rarely occur in large towns where bleeding is at all admissible, and a repetition of the operation can very seldom be proper.

Professor Richter strongly praises the good effect of emetics on erysipelas; but some other writers, probably in a strain of ignorance, or prejudice, represent such medicines as having sometimes occasioned fatal consequences.

Another indication is to promote a gentle degree of perspiration. For this purpose, we may exhibit small doses of the antimonium tartarifatam, or the pulvis ipecacuanha comp., æther vitriolicum; saline draughts with volatile alkali, &c.

Opium and camphor are also proper remedies for allaying irritation.

Whoever has been in the habit of consulting the writings of several celebrated medical authors, will perceive that they place great reliance on bark, as a medicine tending very powerfully to check and cure erysipelatous inflammations. When we mention Mr. John Hunter among such authors, our readers will be inclined, perhaps, to suspect that there must be some foundation for the repute into which this medicine has risen for the complaints under consideration. However, we must confess our own belief, that bark gained credit for its good effects on erysipelas entirely in consequence of the general enthusiasm which once depicted it as a cure for almost every disease of the human frame. The sentiment is corroborated, if not confirmed, by the fact, that the best modern practitioners seem now to consider bark no longer of eminent service in cases of acute erysipelas.

With respect to local applications, in these instances, several kinds have been used by different practitioners. Cold astringent lotions, oily substances, rubefacients, farinaceous, or earthy powders, and emollient poultices, have all been tried. As far as our experience extends, the lotio aquæ lithargyri acetatis is as good an application as can be made to a part affected with the acute species of erysipelas. However, it becomes us to apprise the reader, that the majority of medical writers bestow the greatest praise on the employment of dry mealy powders, such as flour, starch, &c. for topical remedies, with which the inflamed part is to be covered.

Mr. Pearson, strangely enough, speaks in favour of rubefacients, as if the skin were not already reddened enough by the disease; but reserves his highest recommendations for mild warm poultices. Let the surgeon, however, consider the ill consequences and terrible mischief which always occur when suppuration supervenes, and let him beware of the injudicious plan of promoting the latter event.

*Treatment of the adematose erysipelas.*—In this case topical bleeding may be practised; but venesection is hardly

ever allowable. The bowels should be kept open with saline purgatives of the mildest description, and a gentle perspiration ought to be excited, by means of small doses of tartarised antimony, the pulvis ipecacuanha comp., &c. For the purpose of appeasing pain and irritation, the practitioner may prescribe camphor, opium, æther, &c.

When the patient's constitution is in a debilitated condition, tonics are indicated, together with the most nourishing food. Bark, wine, porter, brandy, the confectio aromatica, may now be found of the utmost service.

*Treatment of the malignant or gangrenous erysipelas.*—Little need be said here on this subject, as the mode of treatment is the same as that of mortification in general. See **GANGRENE**.

The grand objects are; to support the patient's strength; to cover the parts affected with emollient poultices; to foment them two or three times a day with a decoction of poppy-heads; to make depending openings for the escape of the matter and sloughs; and remove the dead parts, as soon as it can be done without occasioning the least irritation and pain.

We have frequently seen the gangrenous mischief so extensive in these cases, that amputation of the limb was the only means of saving the patient from destruction. See Richter's *Anfangsgründe der Wundarzneykunst*. Band i. Von der Rose. Pearson's *Principles of Surgery*. Cullen's *First Lines of the Practice of Physic*. Cooper's *First Lines of the Practice of Surgery*.

**ERYSIPHE**, in *Agriculture*, a term applied by some to that vegetable disease generally known by the name of mildew. See **MILDEW**.

**ERYSTHIA**, in *Ancient Geography*, a town of the island of Cyprus. Steph. Byz.

**ERYTHEIA**, an island of Iberia, in the ocean. According to Strabo, it was separated from the continent by a large strait of a stadium, or, according to Pliny, of 100 paces. It was near Gades. Its name was derived from the Phœnicians, who, having inhabited the banks of the Erythrean sea, came to settle here. It was also called *Aprodisias*, or the isle of Venus, and the isle of Juno. See **GADES**.

**ERYTHEMA**, in *Surgery*, (from *ερυθρο*, red.) The celebrated Cullen distinguished two classes of erysipelatous inflammations. When the disease was an affection of the skin alone, and very little of the whole system, or when the affection of the system was only symptomatic of the external inflammation, he called the disease *erythema*; but when the external inflammation was an exanthema, and symptomatic of an affection of the whole system, he named the disease *erysipelas*, which see.

“An Erythema, Rose, or St. Anthony's Fire, (says Dr. Cullen) is an inflammatory affection of the skin, with hardly any evident swelling; of a mixed, and not very bright red colour, readily disappearing upon pressure, but quickly returning again; the redness of no regular circumscription, but spreading unequally, and continuing almost constantly to spread upon the neighbouring part; with a pain like to that from burning; producing blisters, sometimes of a small, sometimes of a larger size, and always ending in a desquamation of the scarf-skin, sometimes in gangrene.”

We need not enlarge on the subject of erythema, in the sense of an erysipelas not originating from a constitutional affection, as every useful information, concerning erysipelatous inflammations in general, is to be found in the article **ERYSIPELAS**.

The chief object which we have in view in the present part of this work, is to describe a particular affection of the

skin, named, in consequence of its being occasioned by the use of mercury, the *mercurial erythema*, or *eczema*.

It was perhaps, for the first time, distinctly noticed and described by Mr. Benjamin Bell in his *Treatise on the Venereal Disease*. “It is not an uncommon effect of mercury (says this author) to excite an eruption upon the surface of the body. In some, this appears as a milium rash, somewhat resembling measles; while in others it is considerably elevated, and seems to be produced by a serous effusion between the cutis and scarf-skin. In some the eruption is partial, being confined to particular spots; while in others it prevails generally over the whole body.

“This eruption, or efflorescence, is not attended with pain; but the heat and itchiness which accompany it are, in some instances, so distressful, that it keeps the patient at all times very uneasy, and deprives him entirely of rest.

“The remedies, (observes Mr. B. Bell) which I have found to answer the best, are the internal use of opiates, conjoined with the application of flour or starch-powder to the parts affected. The skin is kept sufficiently cool and easy by one or the other of these powders being from time to time freely applied to the eruption; and, by a proper exhibition of opiates we secure rest during the night. In some instances, however, we are obliged to avoid the use of opiates; for although they may answer the purpose of procuring sleep, they tend evidently to increase the heat and itchiness of the eruption. We find, indeed, that, in some constitutions, opium excites an uneasy itchy sensation over the whole body, even where an eruption has previously taken place: and it is, perhaps, with such patients only, that it cannot be employed in the treatment of this eruption.

“The eruption to which I allude, (adds Mr. Bell,) appears to arise entirely from the effect of mercury upon the system; but it does not seem to depend upon any particular preparation of the remedy. It takes place indiscriminately from all of them; and not more readily from unction than from those preparations that are used internally.” See a *Treatise on Gonorrhœa Virulenta and Lues Venerea*; by B. Bell, vol. ii. p. 228.

Since this gentleman published the foregoing work, the mercurial erythema has excited considerable attention, and several writers, viz. Drs. Moriarty, M<sup>c</sup>Mullin, and Spens, and Messrs. Alley and Pearson, have endeavoured to render our knowledge of the subject more extensive.

Dr. M<sup>c</sup>Mullin judiciously observes, that eruptions of various kinds are very common symptoms of syphilis, but a very unusual effect of mercury. Hence, until the real nature of the mercurial erythema was ascertained, whenever the affection occurred in patients undergoing a mercurial course for syphilitic complaints, it was naturally enough considered as an anomalous form of lues venerea. The mercury was consequently pushed to a greater extent, in proportion to the violence of the symptoms, and from the cause of the disease being thus unconsciously applied for its removal, it could not fail to be aggravated, and hurried on to a fatal termination. At length, the observation of this fact, and of another truth, that a similar eruption did sometimes appear in patients who were using mercury for other complaints, and in whom no suspicion of syphilis could be entertained, led to the important discovery that the eruption was entirely an effect of mercury, and not at all connected with the original disease.

Dr. M<sup>c</sup>Mullin imputes the first explanation of the nature of the mercurial erythema to Drs. Moriarty and Spens, and Mr. George Alley, all which writers published in the course of the same year, viz. 1804. However, the passage which we have quoted above, from Mr. B. Bell's work on

## ERYTHEMA.

the venereal disease, clearly evinces that though the above gentlemen have undoubtedly great merit in having increased our information concerning the disease, yet the latter writer had noticed the affection before them. Indeed, Dr. Spens has had the liberality to make this acknowledgment himself.

According to Dr. M'Mullin, the different appearances which this disease assumes, from its severity and duration, may be best understood by describing it as consisting of three distinct stages. The first stage, says this gentleman, commences with languor, lassitude, and cold shiverings. These symptoms are succeeded by increased temperature of the body, quick pulse, nausea, head-ach, and thirst. The patient is troubled with a dry cough, and complains of difficult respiration, anxiety, and sense of stricture about the præcordia. The tongue is usually moist, and covered with a white glutinous slime. It sometimes appears clean and of a bright red colour in the centre, while the margins remain foul. The skin feels unusually hot and itchy, with a sense of prickling, not unlike the sensation experienced from the application of nettles. The belly is generally costive; but a diarrhœa is often produced by very slight causes.

To continue Dr. M'Mullin's description: on the first, or second day, an eruption most commonly appears, the colour of which is either dark or bright red. The papulæ are at first distinct and elevated, very much like those which occur in rubeola. Sometimes, but not often, the eruption appears like urticaria, and in such instances the disease is observed to be very mild. The papulæ very speedily run together in such a manner as to form a suffused redness, which disappears on pressure. In most cases, it first begins on the scrotum, inside of the thighs, fore-arm, or where mercurial frictions have been made, and the skin of the parts affected becomes considerably swollen. Instances have also been seen in which an eruption of a purplish colour, and accompanied by papulæ, has suddenly diffused itself over the whole body. (See Moriarty on *Lepra Mercurialis*.) Dr. M'Mullin remarks, however, that the latter form of the affection may be considered as uncommon. In every instance which Dr. M'Mullin has seen the eruption was at first confined to a few places, and thence gradually extended, until the different portions of the eruption had united. The papulæ were also rough to the feel. But, in such cases as resemble urticaria, many minute vesicles, interspersed among the papulæ, and containing a serous fluid, make their appearance from the very first. Contrary to what happens in most diseases, accompanied with cutaneous affections, the febrile symptoms are much aggravated, and continue to increase, after the eruption is complete. The pulse in general beats from 120 to 130 in a minute, the thirst continues urgent, and the patient, who is extremely restless, seldom enjoys quiet sleep. Dr. M'Mullin further informs us, that when the eruption has continued in this manner, for a certain period, the cuticle begins to peel off in thin, whitish, scurfy exfoliations, not unlike those observed in rubeola. This desquamation first begins where the eruption made its earliest appearance, and in this order spreads to other parts. About this period the fauces become sore, the tongue swells, and the eyes appear somewhat inflamed.

The duration of this stage is very various; sometimes it continues from ten to fourteen days, and in other cases it terminates in half that time. When the disease has appeared in its mildest form, the patient recovers immediately after this desquamation, a new cuticle having formed underneath. When the disease is severe, however, he has only

experienced the smallest part of his sufferings, and the skin now assumes a new appearance, which Dr. M'Mullin has considered as the second stage.

This author represents the skin as appearing at this period as if studded with innumerable minute vesicles, which are filled with a pellucid fluid. These vesicles (he observes) may be expected, if the patient, at the close of the first stage, should complain of increased itching, and a sense of a burning heat in the parts, from which the cuticular exfoliations have fallen. The vesicles sometimes remain for a day or two; but in general they are burst immediately after their formation, by the patient rubbing the parts, in order to relieve the troublesome itching which he suffers. A ferous acrimonious fluid is discharged, which possesses so disagreeable an odour, that it induces nausea in the patient himself, and those who approach his bed-side. The smell is said to be so peculiar, that it can be easily recognised by any person who has once perceived it. Dr. M'Mullin states, that this fluid is poured out most copiously from the scrotum, groin, inside of the thighs, or wherever the skin forms folds, and sebaceous glands are most numerous. The ferous discharge from the vesicles forms, with the cuticle, incrustations, which Dr. M'Mullin regards as the criterion of the third or last stage.

The same writer observes, that the crusts are generally very large, and when detached retain the figure of the parts from which they have fallen. Their colour is in general reddish, but it sometimes appears dark and dirty. Dr. M'Mullin conceives, that this period of the disease might be termed, with much propriety, the stage of *de-crustation*, in order to distinguish it more fully from the *des-quamation*, which has been already noticed. When the stage of decrustation appears, the fauces become more affected, the eyes intolerant of light, and the tarsi tender, inflamed, and sometimes turned inward. The crusts formed on the face, as in other parts of the body, before falling off, break so as to leave cracks and fissures, which horribly deform the countenance; and in consequence of the great swelling of the face the eye-lids are also completely closed. The back and hairy scalp are said to be the parts most backward in becoming affected, and, according to Dr. M'Mullin's account, they even sometimes escape entirely in very severe cases.

In this stage of the mercurial erythema the patient is under the necessity of avoiding every kind of motion, on account of the pain which it occasions, and which he compares with such a sensation as one may fancy would be produced by a cracking of the flesh. The crusts also fall off in such abundance, that the bed seems as if strewed with the cones of hops.

While the eruption is only making its appearance in one place, it may have attained its most advanced form in another part, so that all the different stages of the disease may be present at one time, in the same individual.

Typhus prevails throughout the whole course of the complaint; but, what is curious, the appetite continues in most cases unimpaired, and sometimes is even voracious.

Dr. M'Mullin also remarks, that when the catarrhal symptoms have continued during the progress of the complaint, they are particularly aggravated in the advanced stage of the case. The anxiety and pain in the breast are likewise stated to be very severe, attended with cough and bloody expectoration, the patient invariably feeling languid and dejected. The pulse becomes frequent, feeble, and irregular; the tongue black and parched; and, at length, diarrhœa, delirium, convulsions, gangrene of the surface of the body, and death, ensue.

## ERYTHEMA.

The mild form of the disease only goes through the first stage, and ends, as we have already described, in a slight desquamation, after a few days. When the affection is severe, however, it is often protracted more than two months, every stage of the eruption continuing proportionably longer; and when, in this manner, it has run its course, it repeatedly breaks out on the new surface, and passes through the same stages.

For the preceding history of the symptoms of the mercurial erythema, we feel ourselves highly indebted to Dr. M'Mullin. See *Edinburgh Medical and Surgical Journal*, vol. ii. p. 25, &c.

With the exception of one case, which Dr. Rutter has inserted in the eighteenth number of the journal just now mentioned, we have no instance recorded, in which the present disorder originated, without the patient being under the influence of mercury. Whether Dr. Rutter's example is to be considered as the same identical disease as the one which we have been describing, we shall not undertake to investigate. We shall only observe, that since it is very possible to mistake other complaints for the real mercurial erythema, we do not consider one solitary fact, resting on the judgment of an individual, who might differ in opinion concerning the nature of the disease, with the next medical practitioner consulted, a sufficient ground for implicitly believing, that such a disease as the mercurial erythema can be produced quite independently of the use of mercury.

In certain habits, every preparation of mercury, and every form of employing this medicine, seem capable of bringing on the disease. As the complaint was first taken notice of in patients who were afflicted with syphilis, it was supposed to be an anomalous form of the venereal disease. But, at last, the repeated appearance of the eruption in persons exempt from all suspicion of having any syphilitic symptoms, made surgeons convinced, that what is now commonly named the mercurial erythema had nothing venereal in its nature. However, since few out of the great number of patients, continually employing mercury, are afflicted with this erythema, medical writers have attempted a further explanation of the difficult subject of causes, by stating, that the mercurial erythema only takes place in such patients as have a certain undefinable peculiarity of constitution. The contemplative reader will at once perceive, that this is a vague and unphilosophical mode of accounting for the production of the disease, as the same sorry kind of explanation may be generally adopted in regard to every disorder, the immediate cause of which is totally unknown. Is it not a greater mark of prudence and good sense to confess our ignorance, under these circumstances, than to offer statements, wishing them to be considered as explanatory, while they do not convey any information whatever on the subject?

It has been supposed by some, among whom is Dr. Gregory of Edinburgh, that the application of cold to the body, while under the influence of mercury, is absolutely essential to the production of the disorder under consideration.

Notwithstanding there can be no reasonable doubt that the mercurial erythema is commonly excited by the use of mercury in some form or another, yet it appears from what Mr. Pearson has stated, that the disease is not always exasperated by a perseverance in the employment of the medicine. On some particular occasions, when this gentleman judged it to be of great moment to continue the mercurial frictions, the eruption neither spread universally, nor was it materially increased. The patients, however, did not get rid of the rash till the mercury was discontinued.

We have already noticed the opinion of Dr. Gregory

and some other practitioners, that exposure of the body to cold, at a time when the system is under the influence of mercury, is absolutely necessary for the production of the mercurial erythema. Mr. Pearson seems to entertain a very different sentiment; for, he observes, that he is not aware of any other cause, than the action of mercury on a particular kind of constitution being concerned. He acquaints us, that he has seen this cutaneous disease occur in private practice as well as the Lock hospital, where the strictest attention has been paid to the temperature of the apartment, to regimen, and to personal cleanliness. He has had no reason to believe that any one season of the year is more conducive to the disease than another; and he states that free exposure to the air, either in winter or summer, has not the least perceptible effect in exciting the eruption.

Mr. Pearson, as a general rule, recommends the employment of mercury to be immediately left off on the first appearance of the eruption; and though he seems to admit that the affection may be relieved by remedies, yet he is doubtful whether any plan of treatment has the power of interrupting its regular course, or abridging its duration. Mr. Pearson would by no means wish to insinuate, however, that the patient may not derive considerable benefit from medical assistance; his sufferings (he owns) may be greatly mitigated; many inconveniences may be remedied; his strength may be supported; and, in short, (says Mr. Pearson,) he may be so conducted through the disease, that his general state of health shall not suffer any material or permanent injury.

It is not enough to discontinue the employment of mercury. In large hospitals, and particularly such as are appropriated to venereal cases, the patient should be immediately removed from those wards which may have their atmosphere vitiated by the breathing of persons charged in general with mercury.

In the early stage of the mercurial erythema, Mr. Pearson recommends small doses, of antimonial powder, with saline draughts, or else the ammonia acetata. A gentle purgative should be given every three or four days, and opium is proper for appeasing the pain and irritation, and procuring sleep. Sometimes, says Mr. Pearson, opium mixed with camphor, or Hoffman's anodyne liquor, will have a better effect than when administered alone. When the discharge is no longer ichorous, and the tumefaction is subsiding, the same surgeon prescribes the liberal exhibition of sarsaparilla and bark. He has also thought, that the general sense of uneasiness has been lessened by the vitriolic acid, which proves at the same time grateful and refreshing.

The diet should be of a light and nourishing quality; but no fermenting liquors can be prudently allowed till the desquamation of the cuticle is somewhat advanced.

In order to diminish the pain arising from the irritation of the skin, the warm bath may be used as often as the patient's strength will permit. His linen and sheets, which are soon rendered hard and stiff by the discharge, should be very frequently changed. Mr. Pearson is also in the habit of covering every part, where excoriations occur, with a soft mild cerate, made of litharge plaster, yellow wax, and olive oil. This application is to be thickly spread on rollers, by which means it may be conveniently put wherever it is needed. The dressing should be changed twice a day.

Dr. M'Mullin has noticed, that, though in the early stage of the mercurial erythema, diaphoretics are indicated, yet the bowels are so irritable, that such medicines can scarcely be employed. For the same reason, he recom-

mends

mends us to be very cautious in giving mineral acids, ripe fruits, &c. This gentleman approves of the patient being kept in rather a warm temperature, and in a place where he can derive the advantage of a quick circulation of air. The bowels being weak, Dr. M'Mullin advises us only to employ the mildest purgatives, when medicines of this class are required.

With regard to the topical treatment, the latter gentleman says, that solutions of sulphate of zinc, and acetite of lead, sulphur ointment, and the decoction of oak-bark, have all been tried, but without any particular good, and he seems to prefer sprinkling the parts with powdered starch. To allay the cough and soreness of the fauces, he advises mucilaginous mixtures, containing a small proportion of opium.

When the incrustations become general, the fever always assumes more of the typhoid type. In this stage bark has been usually prescribed, with a view of supporting the strength; but Dr. M'Mullin remarks, that this medicine can never be given in sufficient quantity, owing to its affecting the stomach, or occasioning diarrhoea. In some instances, he observes, the cold infusion, conjoined with aromatics, has been best retained, and a little opium may be added to the doses. Opium, which this gentleman describes as improper in the first stage, may now be taken without any risk of unpleasant consequences. He states, that wine is the best remedy in this stage of the disease. Porter and diluted spirit are also proper, and the thirst must be assuaged with whey, light broths, and nourishing drinks of every kind. Owing to there being now a large extent of the skin in an excoriated state, the patient cannot at this time generally bear warm bathing, which often brings on a state of syncope, and all that can be done is to wash the parts, in the most tender manner, with tepid water.

For the ophthalmia tarsi, the unguentum zinci vitriolati is recommended, and the linimentum aquæ calcis is said to relieve most effectually the pain which makes the patient feel as if his flesh were cracking.

We shall conclude this article with advising the reader, who wishes to be perfectly acquainted with the subject of mercurial erythema, to consult B. Bell's Treatise on Gonorrhœa Virulenta and Lues Venerea, vol. ii. p. 228. Pearson on the Effects of various Articles in the Cure of Lues Venerea. Edit. 2. p. 165. An Essay on a Peculiar Eruptive Disease arising from the Exhibition of Mercury, by G. Alley, Dublin, 1804. A Description of the Mercurial Leprosy, by Dr. Moriarty, Dublin, 1804. History of Three Cases of Erythema Mercuriale, by Dr. Spens, in Edinb. Med. and Surgical Journal, vol. i. p. 7. Essay on Erythema Mercuriale, by Dr. M'Mullin, in Edinb. Med. and Surgical Journal, vol. ii. p. 25. Case of Erythema not occasioned by Mercury, by John Rutter, M. D. in Edinb. Med. and Surgical Journal, vol. v. p. 143.

ERYTHRÆ, in *Ancient Geography*, a town of Greece, in Bœotia. Pliny. It was situated near mount Citheron, according to Euripides. Some authors place it in the territory of Plataea, to the east of this town.—Also, a town of Greece, in Thessaly, situated upon the river Erypæus, according to Strabo.—Also, a town of Greece, in Cœtolia, near Eupalium.—Also, a town in the isle of Cyprus, called Paphos.—Also, one of the twelve towns of Asia Minor, in Ionia, according to Pliny. Strabo says, that it gave name to the Erythrean Sibyl. He says also, that it had a port, called Cyssus, in which were four isles called Hippis. This town was built by Nilæus, the son of Codrus. In the town was a temple of Hercules, one of the most stately edifices in all Asia. Erythræ took part, on all occasions, with the Romans, who rewarded its fidelity with ample privi-

leges, and considerably enlarged its territory. It is now a village, named Erethri.—Also, a town of Africa, in Libya.

ERYTHRÆA, in *Botany*, *ερυθρα*, red, a name given by Renealm to the *Chironia Centaurium*, (*Gentiana Centaurium* of Linnæus), on account of its red colour, unusual in the Gentian tribe. This writer controverts the universally received opinion of its being the *ερυθρα* of Dioscorides, because the latter is said to prefer watery situations. But neither this, nor indeed any other of his arguments, is of much weight; for the *Chironia Centaurium* often occurs in low and wet places, and according to Dr. Sibthorp is very frequent throughout Greece. *Chironia spicata*, which Dioscorides would hardly distinguish from it, always grows in marshy spots, and is found on the coasts of Greece, as may also *Chironia pulchella*, though scarcely distinguished by any body from the common kind when Dr. Sibthorp visited that country, and therefore not noted by him.

ERYTHRÆAN SEA, in *Ancient Geography*, is the ancient name of the *Red Sea*. Indeed, the ancients gave this name to the whole expanse of water that extends from the coast of Ethiopia to the island of Taprobana. This appellation was probably derived from Edom or Esau, whose descendants were called Idumæans, and inhabited the northern part of Arabia. The Idumæans navigated upon the Red sea and the Persian gulf, and also upon the Indian sea, and the oriental name Idumæan signified red. Whence the sea of the Idumæans was called the Red sea, and the Erythrean sea.

ERYTHRÆAN Sibyl. See SIBYL.

ERYTHREAN, an appellation given to Hercules, from a temple which he had at Erythres, in Arcadia.

ERYTHRINA, in *Botany*, from *ερυθρος*, red, on account of the scarlet flowers, whence also it is called Coral-tree. Linn. Gen. 365. Schreb. 486. Willd. Sp. Pl. v. 3. 912. Mart. Mill. Dict. v. 2. Juss. 356. (Coralodendron; Tournef. t. 446.) Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionacea*, Linn. *Leguminosa*, Juss.

Gen. Ch. Cal. Perianth of one leaf, entire, tubular; its margin more or less two-lobed; its base on the lower side furnished with a honey-bearing pore. Cor. papilionaceous, generally of five petals; standard much the longest, lanceolate, ascending, its sides bent downwards; wings minute, somewhat ovate, scarcely longer than the calyx, and hardly reaching beyond the claw of the standard; keel straightish, usually about the length of the wings, sometimes longer, of two petals either separate or united, notched at the end. Stam. Filaments ten, unequal, united below into a tube, slit at the upper edge, a little incurved, half as long as the standard, one of them occasionally separate; anthers ten, oblong. Pist. Germen superior, stalked, awl-shaped, tapering into an awl-shaped style, as long as the stamens; stigma terminal, simple. Peric. Legume very long, protuberant from the seeds, pointed, of one cell. Seeds several, kidney-shaped.

Ess. Ch. Calyx two-lobed, standard much longer than the keel. Wings minute. Legume cylindrical, with many convex seeds.

Obs. *E. herbacea* has the tenth stamen separate; which is also the case with *E. Crista-galli*, whose keel moreover has its petals united into one, and is much longer than in the generality of the species.

The species of this splendid genus are, for the most part, natives of very hot climates in the East or West Indies, and amount in Willdenow, who has paid particular attention to them, and described two new ones, to twelve.

*E. herbacea*, Linn. Sp. Pl. 992. Trew. Ehret. t. 58. found

in Carolina, will support our winters in a green-house, nor does its stem always die down to the root. The flowers form long and very handsome spikes, being of a most vivid though deep scarlet, with purplish stalks and calyx. Seeds scarlet with a black eye.

*E. Corallodendrum*, Linn. Sp. Pl. 992, brought from the West Indies, requires a stove. It has an arborefcnt prickly stem, with flowers much like the former.

*E. mitis*, Jacq. Hort. Schoenbr. v. 2. 47. t. 216, is another similar species in its flowers, but destitute of prickles. It was sent to the Imperial garden from the Caraccas.

*E. Crista-galli*, Linn. Mant. 99. Sm. Exot. Bot. v. 2. 69. t. 95, is perhaps one of the most lately of the whole. This is said to be a native of Brasil, but was raised in the Liverpool garden from seeds brought from the East Indies, probably from the garden at Calcutta. It was in 1805 but a slender prickly shrub about six feet high, with ternate prickly-ribbed leaves. Flowers in large terminal clusters, of a rich unpolished deep scarlet, their standards much broader, and keels much longer, than is usual in this genus; the wings very small and three-lobed, of a greenish white. Tenth filament separate to the very base.

*E. speciosa*, Andr. Repof. t. 443, a plant we have never seen, flowered in the garden of A. B. Lambert, esq., and though supposed to be a native of South America, is said to be perfectly hardy, and to strike very freely from cuttings. Whether it be comprehended under any of Willdenow's species, we are not at all certain. The stem is prickly, thick and strong. Leaflets very broad, with prickly ribs. Flowers scarlet, in very dense spikes. Wings half as long as the standard, which is narrow like the first species; keel not half so long as the wings. If these circumstances are constant, the generic character will require correction.

ERYTHRINUS, in *Ichthyology*, a species of SPARUS and also of SALMO, which see respectively.

ERYTHROCEANEUS, in *Ornithology*, the red and blue maccaw, with a wedge-like tail, and the sides of the head naked and rough. See PSITTACUS.

ERYTHRODANUM, in the *Materia Medica*, a name by which some authors have called the rubia tinctorum, or madder.

ERYTHROIDES, in *Anatomy*, from *ερυθρος*, red, and *ειδος*, form, a name given by some anatomists to the first proper covering of the testicles. It is not now admitted that these bodies are covered by any thing except the fibres of the cremaster and cellular substance of the scrotum, to which, perhaps, the above-mentioned name may have been applied.

ERYTHRONIUM, in *Botany*, from *ερυθρος*, red, in allusion either to the colour of the flower, or to the more unusual blood-like stain in the leaves. Dog's-tooth Violet. Linn. Gen. 165. Schreb. 220. Willd. Sp. Pl. v. 2. 96. Mart. Mill. Dict. v. 2. Juss. 48. (*Dens canis*; Tournef. t. 202.) Class and order, *Hexandria Monogynia*. Nat. Ord. *Sarmentaceae*, Linn. *Lilia*, Juss.

Gen. Ch. *Cal.* none. *Cor.* Petals six, regular, lanceolate, pointed, lying over one another alternately towards the base, spreading gradually, reflexed from about the middle; three of them external, three internal. Nectary two scars, or little scales, at the base of each of the inner petals. *Stam.* Filaments six, uniform, awl-shaped, short; anthers oblong, erect, as long as the filaments. *Pist.* Germen superior, roundish or oblong, with three angles; style simple, shorter than the corolla, taper at the base, and a little bent at that part, otherwise straight; stigmas three, spreading, somewhat cylindrical, furrowed, or notched. *Peric.* Capsule nearly

globular, contracted at the base, of three cells and three valves. Seeds numerous, ovate, pointed.

Eff. Ch. Corolla bell-shaped, of six reflexed petals. Nectary two scars at the base of the three inner ones. Capsule globose, contracted at the bottom. Seeds ovate.

1. *E. Dens canis*. Linn. Sp. 437. Jacq. Austr. v. 5. 31. append. t. 9. Curt. Mag. t. 5. Leaves with a blunt flat point. Style cylindrical. Germen globose, obtuse. Native of mountainous places in Italy, Switzerland, Carniola, Styria, Carinthia and Tartary, flowering in the spring. In our gardens it is a hardy perennial, distinguished by its elliptical radical leaves, very various in breadth, elegantly stained with purple, and its solitary drooping crimson or whitish flower, with pendulous dark purple anthers. No remains of the herbage are to be seen after the end of June. Lobel and several botanists of his time presumed this to be the real *σατυριον* of Dioscorides, nor does it ill accord with the description, though Dr. Sibthorp seems not to have met with the plant in Greece. It cannot, however, be made to agree with the *σατυριον* *ερυθρονιον* of the same author, though the latter appellation seems to have given rise to its present generic name. The old authors made two species on account of the various dimensions of the leaves, which Linnæus reduced to one, but he very improperly made a third variety of the following species.

2. *E. flavum*. (*E. americanum*; Curt. Mag. t. 1113. *E. Dens caris* γ; Linn. Sp. Pl. 437.) Leaves involute at the point. Style club-shaped. Native of the colder parts of North America. It flowered in April 1808, in the gardens of Mr. Loddiges at Hackney, and Mr. Salisbury at Brompton, and was first well determined by Mr. Gawler in Curtis's Mag. The leaves resemble the former, except in having a hooded termination, from the involute edges of the point. Flower deep yellow spotted with red. Anthers and pollen yellow. Style very thick in the upper half. Germen obovate.

3. *E. revolutum*. Leaves flat-pointed? Style cylindrical. Germen elliptic-oblong, acute. Gathered by Mr. A. Menzies on the west coast of North America. The leaves are broadly elliptical, and in our specimens appear pale, and scarcely spotted. Petals purplish, very much rolled back, as in the Martagon Lily. Stamens with unusually long taper-pointed filaments, and pale or yellowish, not dark purple, anthers. Germen elliptic-lanceolate, pointed. Style contracted at the base, but otherwise pretty exactly cylindrical, with much longer stigmas than either of the foregoing.—The whole plant also is larger, and appears to us unquestionably distinct. The discovery of this species in America renders the original name of the last so exceptionable, that we hope we may be pardoned for changing it before it is adopted in any regular synoptical work, otherwise it would be too late. S.

ERYTHROPTHALMUS, in *Ichthyology*. See CRPRINUS.

ERYTHRORHIZA, in *Botany*, *ερυθρη ριζα*, a red root; Michaux Fl. Boreali-Amér. v. 2. 36. t. 36, is *Galax aphylla*, which see.

ERYTHROXYLUM, *ερυθρον ξυλον*, red wood. Brown. Jam. 278. Linn. Gen. 228. Schreb. 307. Willd. Sp. Pl. v. 2. 746. Mart. Mill. Dict. v. 2. Juss. 253. Class and order, *Decandria Trigynia*. Nat. Ord. *Tribilata*, Linn. *Malpighie*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, turbinate, very small, withering, in five ovate acute segments. *Cor.* Petals five, ovate, concave, spreading. Nectary an upright, coloured, notched scale, attached to the base of each petal. *Stam.* Filaments 10, the length of the corolla, connected at the base by an

abrupt membrane; anthers heart-shaped. *Pist.* Germen ovate, superior; styles three, thread-shaped, distant, the length of the stamens; stigmas thickish and obtuse. *Peric.* Drupa ovate, of one cell. *Seed.* Nut oblong, with four obtuse angles.

*Ess.* Ch. Calyx turbinate. Petals five, each with a notched nectariferous scale at its base. Stamens connected at their base. Drupa of one cell.

This genus, founded by Browne, consists of two species only in his work. 1. *E. areolatum*, Linn. Sp. Pl. 612. Brown. Jam. t. 38. f. 2. and t. 14. f. 3. (*E. carthaginense*; Jacq. Amer. 134. t. 87. f. 1.) This is called, in Jamaica, Red Wood, or Iron Wood, and is said to be excellent for the size of the tree, which is not above five or six inches in diameter. The leaves are obovate, two inches long, marked with two lines at the back, which circumscribe the part that was exposed before each leaf expanded. Flowers starry, white, fragrant, on simple, clustered, lateral stalks.

2. The second species of Browne has been neglected by following authors, probably as a variety of the first. He describes it as different in its manner of growth, with smaller rounder leaves.

Cavanilles and Lamarck have much increased the number of species, so that they now amount in Willdenow's work to 12, all except the above unknown to Linnæus. They are natives either of South America, Madagascar, or the islands of Mauritius and Bourbon, and were chiefly gathered by Commerçon. The French call many of them Bois d'huile. The wood is, in some instances, said to have a very strong and disagreeable smell while burning.

ERYX, in *Ancient Geography*. See ERIX.

ERYX, in *Zoology*, a species of ANGUIS, being the *Anguis dorso trilineato* of Boddaert, above cinereous, with three black lines, and light blueish beneath. It is found in England, and in America.

ERZ, or ERZI, in the *Botanical Writings of the Ancients*, a word used originally by the Hebrews, and by them made the name of the cedar.

ERZEN, in *Geography*, a town of Germany, in the circle of Lower Saxony, and principality of Calenberg, seated on the Humme; 7 miles S.W. of Hameln.

ERZERUM, or ARZERUM, a city of Asiatic Turkey, and capital of a pachalic to which it gives name, and is a part of Armenia, situated near the head of the Euphrates, at the foot of a chain of mountains which are usually covered with snow till the latter end of spring. The town is surrounded with a double wall, and defended with some square towers; the houses are mean, and none of them large. The suburbs are inhabited by Christians. Of the inhabitants, they count 18,000 Turks, of whom two-thirds are Janizaries; 6000 Armenians, who have an archbishop, and two churches; and 400 Greeks, who have a bishop, and one mean church. The Greeks are mostly employed in the manufacture of copper, brought from some mines three days journey from the city; this, and the manufacture of the skin of a species of martin, are the only articles of their commerce. Erzerum is the staple of the merchandize of India, especially when the Arabians infest the environs of Aleppo and Bagdad. This merchandize consists of silk from Persia, cotton, painted linens, spices, rhubarb from Bucharia, madder from Persia, zedoary, &c. This town was one of the last which was taken from the Greek emperors by the Arabians; 250 miles N.N.E. of Aleppo, and 510 E. of Constantinople.

ERZGEBIRG. See ERTZGEBIRGE.

ESAPHE, from εσαφη, *I feel with the fingers*, a word used by Hippocrates, to express the touching of the mouth of the uterus, in order to discover its state of disease.

ESAU, in *Biography*, the son of Isaac and Rebecca, and the twin-brother of Jacob, whom he succeeded at his birth, was born in the year 1836 B.C. At his birth he was covered with hair, indicating great bodily strength, by which he was fitted for the kind of life to which he afterwards devoted himself. As he was fond of hunting, he supplied his father with a variety of delicious food, and became his favourite. Jacob, however, was the favourite of his mother, and by means of a circumstance mentioned in his history, supplanted Esau of his birth-right, which he consented to barter for a mess of red pottage, that had been prepared for their father, during his absence. Hence he and his posterity derived the appellation of Edom, signifying red. At the age of 40 years Esau distressed his parents by marrying two wives out of idolatrous Canaanitish families, with which the posterity of Abraham were prohibited from forming any connection. In process of time, he regained his father's favour, and as death approached, Isaac determined to confer his last prophetic benediction on Esau, as his first-born son and heir. The artifice of his mother, however, counteracted his purpose; and she contrived to impose upon Isaac, and to obtain the father's parental blessing for her son Jacob. Esau was indignant on account of the treatment of his brother; and determined to kill him as soon as their father should die.

Rebecca again interposed, and sent Jacob away to her brother Laban, with whom he might be secure from the threatened vengeance of his brother. During the period of separation, which lasted several years, Esau married a wife of the family of Ishmael, and removing to mount Seir, acquired great power and wealth. When Jacob returned, after long absence, to his father's country, with a numerous family, and large flocks and herds, he dreaded his brother's displeasure; and though they had an amicable and affectionate interview, he entertained suspicion of remaining resentment, and instead of complying with the wishes of his brother, who was desirous that he would settle in his neighbourhood, he dwelt in Shechem. After their father's death they lived in peace and amity; but as their possessions enlarged, and there was not sufficient room for them in the land in which they were strangers, Esau returned to mount Seir, where his posterity multiplied under the denomination of Edomites. (See EDOM.) The time of his death is not mentioned, but bishop Cumberland thinks it probable that he died about the same time with his brother Jacob, at the age of about 147 years. Genesis, ch. xxv—xxxvi.

ESAU, in *Geography*, a mountain of Arabia, in the country of Yemen, 4 miles N. of Udden.

ESAULOVO, a town of Russian Siberia, in the government of Kolivan; 36 miles E.S.E. of Krasnoiarsk.

ESBONITÆ, in *Ancient Geography*, a people of Arabia-Petræa, who took their name from the capital, which was seated in the mountains over-against Jericho.

ESBUS. See HESHBON.

ESCACENA, in *Geography*, a town of Spain, in the country of Seville; 20 miles W. of Seville.

ESCAILLON, a river of France, which runs into the Scheldt, about two miles above Valenciennes.

ESCALA, LA, a town of Spain, in the province of Catalonia, on the coast of the Mediterranean; 22 miles E. of Gerona.

ESCALADE, or SCALADE, in the *Military Art*, a furious attack of a wall or a rampart; carried on with ladders, to pass the ditch, or mount the rampart; without proceeding in form, breaking ground, or carrying on regular works to secure the men.

When the troops are prepared to pass the ditch, either with

with the assistance of boards, hurdles, and fascines, when it is muddy, or with small boats of tin, or baskets covered with skins, or oil-cloth when it is deep, and filled with water, a party must be placed on the counterescarp, opposite to the landing-place, ready to fire at the garrison if they are alarmed, and oppose the mounting on the rampart. If the ditch is dry, the ladders are fixed in some place farthest distant from the centre; and as soon as they get upon the rampart, they put themselves in order to receive the enemy; if the centre should be surprised, and silently overcome, the detachment halloos to break open the gate, and to let in the rest of the party. If the ditch is wet, the rampart high, and provided with a revetement, it will be difficult to surprise the town in this way; but if there is no revetement, the troops may hide themselves along the outside of the rampart till all are over. Since the invention and use of gun-powder, and the walls of cities have been flanked, they are seldom taken by escalade.

ESCALANA, in *Geography*, a town of Spain, in Old Castile; 14 miles N.N.E. of Segovia.

ESCALANTE, a town of Spain, in the province of Biscay; 15 miles E. of Santander.

ESCALAON, a town of Portugal, in the province of Beira; 16 miles N. of Almeida.

ESCALLION, in *Botany*. See SCALLION.

ESCALLONIA, so called by the younger Linnæus, at the recommendation of Mutis, in honour of a learned Spaniard named Escallon, the pupil of Mutis in botany, mathematics and philosophy, and his inseparable companion during his abode in New Spain. This gentleman discovered the shrub in question, as well as a vast number of new or rare plants besides, in his various journeys through New Granada, most of which were, by Mutis or himself, communicated to Linnæus or his son. A very fine plant was originally chosen by Mutis for the above purpose, of which a specimen and drawing were sent to Linnæus; but it proved, on a careful examination, to be a *Loranthus*, and remains undescribed in the Linnæan herbarium.—Linn. Suppl. 21. Schreb. 152. Willd. Sp. Pl. v. 1. 1149. Mart. Mill. Diet. v. 2. Juss. 321. Class and order, *Pimentaria Monogynia*. Nat. Ord. *Onagrea*, Juss.

Gen. Ch. Cal. Perianth of one leaf, inferior, hemispherical, with five large, spreading, ovate, acute, permanent teeth. Cr. Petals five, equal, inserted into the calyx, tongue-shaped or obovate, obtuse, a little distant from each other, longer than the calyx-teeth. Stam. Filaments five, equal, erect, awl-shaped, inserted into the calyx between the petals, opposite to its teeth and about the same length; anthers incumbent. Pist. Germen half invested with the calyx, globular; style cylindrical, straight, the length of the stamens; stigma capitate, umbilicate. Peric. Berry roundish, of two cells, crowned with the calyx-teeth. Seeds very numerous, minute.

Ess. Ch. Berry of two cells, with many seeds. Calyx encompassing the fruit. Stigma capitate. Petals five, inserted into the calyx.

1. *E. myrtilloides*. Linn. Suppl. 156. Sm. Pl. Ic. t. 30.—Leaves finely serrated, minutely pointed, veiny beneath. Flowers solitary.—Gathered in New Granada by Escallon.—Stem shrubby, branched, slightly angular, with a smooth deciduous bark. Young branches numerous, alternate, short, simple, leafy, each terminated by a solitary, stalked, terminal flower. Leaves alternate, spreading, about three-quarters of an inch long, obovate, obtuse with a minute point, minutely serrated, especially towards the end, smooth, deciduous; with no perceptible veins on the upper side; paler and veiny beneath; the base tapering down into a

short, often fringed, footstalk, each of whose edges unites at their base with a glandular toothed angle or rib in the branch. *Stipulas* none. *Flower-stalks* angular and glandular. *Petals* about thrice as long as the calyx-teeth, apparently white, erect, their extremities reflexed. *Berry* black? the size of a large pea, or bigger, crowned with the calyx and base of the style.

2. *E. ferrata*. Sm. Pl. Ic. t. 31.—Leaves serrated, somewhat abrupt, smooth and without veins at the back. Flowers solitary.—Gathered about the straits of Magellan, by Commerçon; in Staten land, (not Terra del Fuego,) by Mr. Archibald Menzies.—A humble branched smooth shrub, with something of the aspect of a *Vaccinium*. Branches alternate, somewhat zig-zag, angular, with a pale smooth bark; those of the present season green, leafy, straighter, each bearing a solitary, terminal, stalked flower. Leaves deciduous, alternate, obovate, obtuse, often abrupt or retuse, with a minute central point or tooth, equally serrated or somewhat crenate, very smooth; slightly veiny above; pale and destitute of lateral veins beneath, though furnished like the former with a strong central rib. *Footstalks* smooth and entire, as are the angles of the branches. *Stipulas* none. *Flower-stalk* smooth. *Petals* white, spreading, not recurved. Top of the *germen* violet. All the parts of fructification, except the petals, are but one-third the size of the former. The little *berries*, crowned with the permanent style, appear to remain through the winter, and their upper part, above the calyx-teeth, easily separates like a lid as they ripen, exposing the pulp full of small seeds, with its transverse partition.

3. *E. glandulosa*. Leaves double serrated, acute, glandular at the back like the branches. Flowers somewhat corymbose.—Gathered in Chili by Mr. A. Menzies.—Branches wand-like, roundish, leafy, when young clothed with abundance of prominent glandular tubercles. Leaves alternate, when full grown near an inch and half long, obovate, pointed, strongly and doubly serrated; smooth or slightly downy above; veiny, and rough with innumerable prominent resinous glands, beneath; tapering at the base into a shortish glandular footstalk. Each leaf is accompanied by an axillary tuft of smaller ones, the rudiments of future branches. *Stipulas* none. *Flower-stalks* several about the tops of the branches, axillary and terminal, simple or subdivided, each about an inch long, angular, glandular like the branches, as is also the base of the calyx. *Bractæas* few, at the base or subdivision of each stalk, linear, glandular. *Calyx* about the size of the last. *Petals* more like the former, and somewhat longer, with rounded, reflexed extremities. *Style* furrowed, surrounded at its base with an annular lobed gland or nectary, of which we can find no traces in the other species. *Germen* of two cells. The fruit we have not seen. S.

ESCALONA, in *Geography*, a small, tolerably built, walled town of Spain, in the province of New Castile, with several suburbs, seated on an eminence defended by a castle, in a fruitful spot watered by the Alberche, 20 miles N.W. of Toledo, and 32 S.W. of Madrid. It has four churches, and two convents.

ESCALOP *Fossil Shells*, in *Conchology*, are described by Da Costa (*Conchol.* p. 247.) as found in the lime-stone quarries at Thame in Oxfordshire; Mr. Walcot, in his "Petrefactions found near Bath," has also described a singular kind of shell, as found in the clay on the side of the road between Claverton-Down and village, and in the free-stone at the quarries near King's Down; and another kind found in a slaty loam at the limestone quarry near the Crescent in Bath.

**ESCAMBIA**, one of the most considerable rivers that fall into the bay of Pensacola, in West Florida, discharges itself near the head of the north branch, about 12 or 15 miles from Pensacola, through several marshes and channels which have a number of islands between them, that are overflowed when the water is high. The course of this river from an unknown source is very winding. The lands on each side are, in general, rich, low, or swampy, or well adapted for the culture of rice or corn. The numerous rivulets that fall into this river from the high country about it may be led over every part of the rice lands, at any season of the year. The islands at the mouth of the river, of which some are considerable in extent, are not inferior for rice to any in America.

**ESCAMBIO**, from the Spanish *cambiar*, to change, was anciently a licence granted any one for making a remittance, or giving a bill of exchange to another, beyond sea.

For, by stat. 5 Rich. II. no person might exchange, or return money beyond sea, without the king's licence.

**ESCAMUS**, in *Ancient Geography*, a river of Mœsia, which has its source in mount Hæmus.

**ESCAPE, FIRE.** See **FIRE-ESCAPE.**

**ESCAPE**, in *Law*, an evasion out of some lawful restraint, either by violence or stealth.

Escapes are either *voluntary*, or *negligent*.

*Voluntary*, are such as are, by the express consent of the keeper to whose custody, in civil actions, the debtor has been committed; after which, he can never retake his prisoner again, (3 Rep. 52. 1 Sid. 330.) though the plaintiff may retake him at any time, (stat. 8 or 9 W. III. c. 27.); but the sheriff must answer for the debt.

*Negligent* escapes are where the prisoner escapes without his keeper's knowledge or consent; and then upon fresh pursuit the defendant may be retaken, and the sheriff shall be excused, if he has him again before any action brought against himself for the escape. (F. N. B. 130.) A rescue of a prisoner in execution, (which see,) either going to gaol or in gaol, or a breach of prison will not excuse the sheriff from being guilty of and answering for the escape; for he ought to have sufficient force to keep him, since he may command the power of the county (Cro. Jac. 419.)

An escape of a person arrested upon criminal process, by eluding the vigilance of his keepers before he is put in hold, is an offence against public justice; and the party himself is punishable by fine or imprisonment. (2 Hawk. P. C. c. 122.) But the officer permitting such escape, either by negligence or connivance, is much more culpable than the prisoner. Officers, therefore, who, after arrest, negligently permit a felon to escape, are punishable by fine (1 Hal. P. C. 600.); but *voluntary* escapes, by consent and connivance of the officer, are a much more serious offence; for it is generally agreed that such escapes amount to the same kind of offence, and are punishable in the same degree, as the offence of which the prisoner is guilty, and for which he is in custody, whether treason, felony, or trespass; and this, whether he was actually committed to gaol, or only under a bare arrest. (1 Hal. P. C. 590. 2 Hawk. P. C. 124.) But the officer cannot be thus punished, till the original delinquent hath actually received judgment or been attainted, upon verdict, confession, or outlawry, of the crime for which he was so committed or arrested; and otherwise it might happen, that the officer might be punished for treason or felony, and the person arrested, and escaping, might turn out to be an innocent man. But before the conviction of the principal party, the officer thus neglecting his duty may be fined and imprisoned for a misdemeanor. (1 Hal. P. C. 588, 9. 2 Hawk. P. C. 134, 5.) See **RESCUE.**

**ESCAPE warrant.** If any person committed or charged in custody in the king's bench, or Fleet prison, in execution, or on mesne process, &c. go at large; on oath thereof before a judge of the court where the action was brought, an escape warrant shall be granted, directed to all sheriffs, &c. throughout England, to retake the prisoner, and commit him to gaol when taken, there to remain until the debt is satisfied; and a person may be taken on a Sunday upon an escape warrant. Stat. 1 Anne, cap. 6.

**ESCAPEMENT**, in *Horology*, is an ingenious mechanical contrivance for transmitting, in a modified way, and at equidistant intervals of time, the maintaining power of a clock or watch to the regulator, whether balance or pendulum, in order to restore that loss of motion in every vibration or oscillation, which necessarily arises from the friction of the acting parts, and the resistance of the air in every machine. It has been said, under the article **CLOCK**, that the maintaining power, whether consisting of a weight or spring, when suffered to expend itself unrestrained, would make the wheel-work run on with an increasing velocity, until the obstacles to motion, such as the friction in the teeth and at the pivots, the resistance of the air, &c. fixed the maximum of velocity with which it could expend itself; at which period the friction and resistance would jointly operate as a regulator, whilst they and the maintaining power remained unaltered, and the machine so circumstanced would greatly resemble a common kitchen-jack; and if an index were inserted on the arbor of the first or slowly moving wheel, it would indicate such portions of time as the ratio between the maintaining power and the regulating friction and resistance of the air taken together would produce; but it is obvious, that every alteration produced in the friction by wear, foulness, &c. or in the density of the air by the state of the atmosphere, would affect the indication so much, as to render it extremely irregular; hence the balance and the pendulum were successively invented and applied to regulate the indication of time by their isochronous vibrations; but then as both these regulators have alternate motions backwards and forwards, they could neither of them be applied immediately to check a wheel that moves continually in one direction, without the intervention of some contrivance, connected both with the wheel and regulator, which should convert a direct circular motion into a motion changing its direction by perpetual alternations. To devise and execute a piece of mechanism that should perform such an office steadily and accurately, required much science as well as mechanical skill, and the invention once executed was denominated an *escapement*, or by contraction among the workmen *scapement*, because it suffers a tooth of the wheel, with which it acts, to *escape*, or pass on, at such intervals of time as are measured by the regulator, which wheel is therefore also called the *escapement wheel*.

From this short account of the origin and office of an escapement, the reader will perceive, that the accuracy of its construction constitutes one of the most essential considerations in an horometrical machine, it being an indispensable condition, that the successive impulses taken from the maintaining power through the medium of the wheel-work, and given to the regulator, should be so modified, as to disturb as little as possible the natural isochronism of the regulator, or, if it do disturb it, that it should somehow compensate that disturbance. Hence it becomes necessary, that the workman, or mechanician, should be fully acquainted with the theory of the natural isochronism of his proposed regulator, when he undertakes to design and execute his escapement; he must not only know how much of the

## ESCAPEMENT.

maintaining power will be sufficient to balance the loss sustained in the natural length of a vibration, by reason of friction and the resistance of a standard medium, but he must consider and indeed ascertain, by theory or experiment, or both, at what part of the arc of vibration the power must be applied; likewise how long the impulsion shall continue to act, and whether that action ought to be uniform, increasing, or decreasing in its intensity. These and similar considerations have produced, as might be expected, a great variety of constructions of an escapement, both with regard to their external shape and *modus operandi*. As a good escapement is of the utmost importance in the useful art of clock-making, and as we have no author in the English language who has given us the different constructions in historical order, together with such remarks as may enable the reader to judge of their respective excellence, we will devote some time to the detail of both the theory and practical construction of such different escapements as seem to merit a general notice.

But before we enter upon our description and examination of different escapements of clocks and watches, as the reader has not yet had an opportunity of perusing the article **PENDULUM**, and as all escapements derive their shape and manner of action from the relation they bear either to the laws of its motion, or to those of a moving balance, it will contribute greatly to his better understanding the subject, if we premise first some of the chief circumstances which relate to the theory of a free pendulum, and to the influence that any external impulse will have on it when applied to become the regulator of a clock; and secondly, if we explain the theory of a balance's motion, which we have purposely reserved for this place by reason of its intimate connection with the escapement.

1. In *fig. 1. of Plate XXXI. of Horology*, let *CD* represent a *free pendulum*, or pendulum that has no weight but what is collected at the centre of oscillation or point *D*, and let the arc *DB* represent a semi-vibration round the point *C*, taken as the centre of motion or point of suspension, at which we will suppose there is no friction, then if the resistance of the air and rigidity of the string or rod were not to interfere, when the pendulum was once removed from its natural or perpendicular situation *CD* to *B*, and suffered to descend again by the sole force of gravity, it would acquire such a velocity at its lowest point *D*, by means of the accelerating force of gravity, as would, under these circumstances, carry it up an equal semi-vibration or arc *DG*, the increments of accelerated motion being equal in the arc *BD* to the decrements of retarded motion in the equal arc *DG*, the same reasoning would apply in the returning vibration from *G* to *B*; the velocity acquired at *D* by the descent from *G* to *D* would carry the pendulum again up to *B*, and the consequence would be, under such *natural* circumstances, if they could be effected, that there would be a perpetual alternation of vibrations of the same length, which would consequently be isochronal with respect to each other, so long as the pendulum remained of the same length; and such a pendulum would of itself be a perfect time-measurer, and would only want a register to indicate the number of its vibrations, to make it a complete regulator or chronometer: but the fact is, the friction and rigidity at the point of suspension cannot by human art be entirely annihilated, though ingenuity can greatly diminish it; nor can the obstacle to free motion arising from the resistance of the air be removed, or even rendered uniform; hence it is found that when a pendulum is drawn aside from its point of rest, every succeeding vibration, after motion has commenced, is somewhat shorter than the pre-

ceding one; until after some hours have been spent in alternate vibrations continually shortening, the pendulum finds its original point of rest; the time expended in doing this is longer in proportion to the diminution of friction, the air and other circumstances remaining unchanged. Ferdinand Berthoud, the famous French clock-maker, made some experiments to ascertain this fact, and constructed the knife-edge suspension of a second's pendulum, with a heavy lenticular ball, so free from friction, that an arc of vibration of  $10^\circ$  was not reduced to  $15'$  till  $29^h 46^m$  had elapsed; but notwithstanding every attempt to reduce the friction, the pendulum came to rest at last. From this short view of the tendency of a pendulum to come to rest after it has had a motion communicated to it, we clearly perceive the necessity of making some auxiliary additions to the natural force of gravity, in order that the pendulum may keep up the length of its original vibration in every succeeding one, notwithstanding the obstructions which continually oppose the operation of gravity; these auxiliary additions to the motion, produced by gravity only, constitute the operation of the maintaining power, modified by the wheel-work and escapement, in every pendulum clock; and hence arises a *disturbance* in the *theory* of the free pendulum, which makes such a theory no farther of use in clock-work, than as it affords certain laws and a scale of forces, such as the mechanician may labour to imitate, by modifying the joint agency of his *auxiliary additions* and of the operation of gravity, so that they shall act in concert; which imitation is to be effected principally, as to its *mode*, by the escapement, the maintaining power being concerned only as to the *quantity* of any additional power to be applied in aid of gravity.— Now, if we suppose the pendulum at the situation *B*, or extremity of its arc, and draw *AB* perpendicular to the vertical line *CD*, and *BE = CB* perpendicular to the line *AB*, or, which is the same thing, parallel to the line *CD*; also, if we draw *BF* a tangent to the arc at the point *B*, and from the point *E* demit the line *EF* upon it, to form a right angle at *F*, in which case the line *FE* will be parallel to the line *CB*, *BE* will represent the force of gravity, which, by the resolution of forces, is equivalent to *BF* and *FE*; but *FE* is perpendicular to the tangent, or is in the direction *CB* of the radius, and therefore can neither accelerate nor retard the motion, whilst *BF*, being in the direction of the tangent, or perpendicular to the radius, is wholly employed in accelerating or retarding the pendulum's motion: hence, the line  $BE : BF ::$  the force of gravity : the accelerating force; but from the similar triangles *BEF*, *CBA*,  $BF = CB$ , and  $BF = BA$ , therefore, by substitution,  $CB : BA ::$  force of gravity : accelerating force, and consequently the accelerating force =  $\frac{\text{gravity} \times BA}{CB}$ ,

in which expression gravity and the radius *CB* are invariable, therefore the accelerating force varies as the sine *BA* of the arc of vibration. From this law of variation of the accelerating force of a body moving in a circular arc, it follows, that the longer arcs require longer times than the shorter arcs in the proportion of  $34 : 29$ , as Huygens has demonstrated; for the sine does not increase so fast as the arc, which it ought to do, to make the vibrations of the same pendulum in different arcs isochronal: if, however, the body could be made to move along the chord or straight line *BD*, instead of the arc *BD*, then the vibrations of different lengths would be isochronal, because two similar bodies will run down each a separate chord of different lengths to the lowest point of the same circle in the same time, namely, in the time that each would take in falling through

## ESCAPEMENT.

through the whole diameter of the circle, and the acquired velocity of each, at the lowest point, would be in proportion to the length of its chord. But the mechanician has not attempted to make his pendulum vibrate in chord lines, which probably is impracticable, but has invented another curve, called the cycloid, generated by a point in a circle revolving on a straight line, which curve possesses this peculiar property, that the accelerating forces, which a body acquires by moving along it, are exactly proportionable to the arcs, (see CYCLOID,) so that a pendulum vibrating in this kind of curve, will perform its long and short vibrations in the same time. This property of the cycloid was first discovered by the celebrated Huygens, who owed much of his celebrity to it, and adopted a contrivance for making a pendulum move in such a curve, which will be described under our article PENDULUM, and also the reasons will be given why it was laid aside in the practice of clock-making. It may be proper, however, to remark here, that with a pendulum vibrating in the arc of a cycloid, with all its weight collected in the ball, and its length rendered invariable, if such a pendulum could be made, it would, notwithstanding, be of consequence what the nature of the escapement were, because though the variations in the arcs, arising from varied gravity alone, would not affect the times of the successive vibrations, yet, when additional force is applied in aid of gravity, by means of the maintaining power and escapement, the uniform law of acceleration just described would be partially disturbed by such addition, though the disturbance would be less perceptible than in circular arcs of considerable extent.

When, however, a pendulum vibrates in a small arc, it is demonstrable that such an arc differs very little from a cycloidal arc near its lowest point, nay almost coincides with it; it is also found from experience, that a heavy ball is less disturbed by the requisite additional force, communicated by the maintaining power, than a light one, as might be inferred from theory; on which two accounts the prevailing practice among clock-makers is, to make such escapements for a pendulum as require but short vibrations, and, in order to gain momentum, to append a heavy ball; and it has been discovered, and is now indeed an acknowledged fact, that a regulator with an exact compensation for the effects of variable temperature in its pendulum, and that vibrates by means of a good escapement in small arcs, with a heavy lenticular ball, goes with a degree of accuracy beyond what Huygens durst even hope for from his cycloidal contrivance; in effecting which, theory and practice were found to be greatly at variance.

But the cycloidal theory, which, considered as a theory, is not only ingenious, but illustrative of the principal circumstances which relate to the motion of a pendulum, will furnish us with a concise and clear notion how the natural arc and time of a vibration will be altered by an accession of external force to the force of gravity, without some knowledge of which alteration no mechanician can proceed on scientific principles in the construction of an escapement.

Supposing now the pendulum in *fig. 2*, similar to that in the preceding figure, and the arc to be so small as nearly to coincide with the cycloidal curve, let the arc  $GB$  be unbent into the straight line  $bH$ , and with the semi-arc  $DH$ , as a radius, describe the semi-circle  $HLb$ ; set the line  $AB$  from  $H$  to  $M$ , and from  $b$  to  $m$  perpendicular to the line  $bH$ , and join  $mM$ , which line will pass through the centre  $D$ ; from any other points  $I$  and  $K$  in the semi-arc or radius, draw the lines  $IN$  and  $KO$  parallel to  $HM$ , and also the corresponding ones  $in$  and  $ko$  parallel to  $bm$ ,

and we shall obtain the following relations of the properties of the pendulum's motion, *viz.*

1st. The forces of gravity urging the pendulum towards  $D$  from  $B$ , at the points  $I$  and  $K$  of the semi-vibration, will be represented by, and proportional to, the ordinates  $IN$  and  $KO$  of the straight line  $M D m$ ; and the corresponding ordinates  $in$  and  $ko$  will represent, and be proportional to, the retarding forces of the same gravity, at the points  $i$  and  $k$  of the other semi-vibration, and *vice versa* in each half of the returning vibration.

2dly. The velocities acquired by the uniform action of gravity at the points  $I K$  and  $ik$ , will be respectively proportional to the ordinates  $IP$ ,  $KQ$ , and  $ip$ ,  $kq$ , of the semi-circle  $HLb$ ; hence the velocity of the pendulum at the lowest point  $D$ , is to its velocity at any other point of the arc  $I$ , as  $DL$  ( $= DH$ , or whole semi-arc) is to  $IP$ .

3dly. The times of the pendulums vibrating through the portions  $HI$ ,  $IK$ ,  $KD$ , &c. of its arc, will be represented by, and proportional to their corresponding arcs  $HP$ ,  $PQ$ ,  $QL$ , &c. respectively in the semi-circle  $HLb$ ; which proportions will be equally applicable in the ascending portions of the arc  $Dk$ ,  $ki$ , and  $ib$ , which will also be moved through in times proportional to the arcs  $Lq$ ,  $qp$ , and  $pb$ , respectively; if the pendulum is projected from the lowest point  $D$  with the initial velocity  $DL$ , this velocity will be reduced at the point  $k$  to  $kq$ , at  $i$  to  $ip$ , and at  $b$  to nothing, whence the pendulum will return, and the operation of gravity will begin to be reversed.

4thly. If one pendulum describe the arc represented by  $HDb$ , and another describe the arc  $KDk$ , (still supposing them to be cycloidal or very nearly so,) they will describe them in equal times, but their velocities at  $D$ , or greatest velocities, will be respectively proportional to  $HD$  and  $KD$ , or length of their semi-arcs; that is, while a pendulum, projected with the initial velocity  $DL$ , from the lowest point, ascends to the point  $b$ , or extremity of its semi-vibration, another similar pendulum, projected with the initial velocity  $RD$ , will ascend to the point  $k$ , or extremity of its arc,  $DR$  being  $= DK$ , and the same will be true in the descent, where the increments of motion exactly balance the ascending decrements.

5thly. The areas  $MHIN$ ,  $MHKO$ , &c. are proportional to the squares of the velocities acquired in moving down the arcs  $HI$ ,  $HK$ , &c. or to the diminution of the squares of the velocities effected by the retardation of gravity in the returning or ascending semi-vibration.

From a due examination of the relations exhibited in the preceding illustration of the principles of a pendulum's motion, the reader will readily perceive that there is a certain length of the arc of every vibration, whether performed in a circle or cycloidal curve, which corresponds to its maximum of velocity, or velocity at the lowest point; which length, in large circular arcs, is determined by the greatest chord line, but in cycloidal curves, or small circular arcs, is the whole arc itself: he will also understand how, when the weight of a pendulum is given, its accelerating action in any given point of the arc may be appreciated; from which and similar considerations he will be able to form something like an estimate of the effect that will be produced in the above natural relations by the application of an external force of an ascertained quantity, acting in a given manner: for instance, let us suppose that a maintaining power is applied to keep up the vibrations of a pendulum, as in our last figure; that the quantum of power to be added to gravity be to its accelerating force at  $H$  or  $b$ , as  $hm$  is to  $mr$ , which we will suppose to be a number of grains to some number of ounces; and that this additional power

## ESCAPEMENT.

power is applied through the agency of an escapement, which so modifies it, that its action is exerted but a short time, and at the extremity of the arc: the rough conjecture which the reader would be apt to form would be, that as the two forces began to act in concert, a pendulum actuated by them would obey a compound scale of forces, differing in quantity but not in quality from the simple scale of gravity, and that therefore little or no alteration would take place in the time of its vibration; let us see what would be the result according to our theory; from the point  $m$  of the line  $bm$ , of the greatell acceleration or retardation, as the case may be, fet off  $mr$  equal to its representative, for so many grains of augmenting or retarding force, and then  $br$  will be the whole force urging the pendulum towards  $D$ : do the same for every point of  $bD$ , and we get a new scale of forces represented by the dotted line  $rstD$ , and the space  $mDr$ , contained between the two scales  $Dm$  and  $Dr$ , will represent the addition made to the square of the velocity in moving over  $bD$  by the joint action of gravity and of the maintaining power. Then if we make the area  $Duv$  equal to the area  $Dhm$ , by leaving out as much space parallel to the perpendicular  $bm$ , as we take in beyond the hypotenuse  $mD$ , the point  $u$  will limit the excursion or extent of the returning, as well as of every succeeding vibration, because the area of the triangle  $Duv$  is proportional to the square of the velocity, and  $u$  is therefore the point where the initial velocity  $DL$  will be extinguished. Lastly, if the arc  $bw$  of the semi-circle be bisected, its half will very nearly represent the contraction effected in the time of the outward semi-vibration, agreeably both to theory and practice; and in a similar manner might be estimated the effect to be produced on a natural vibration, or vibration from simple gravity, by any accession of external force differently applied: in the instance we have given, a temporary impulsion would evidently make a greater derangement when given at the extremity of the arc, than if it had been given at  $I$ , and greater at  $I$  than at  $K$ , and consequently the least derangement would have arisen if the impulsion had been given at the lowest point  $D$ , which is worthy of recollection; though the fact is, that most of the escapements, that are not of the detached kind, continue to act for a sensible time, and, after all, the thing principally aimed at in modern practice is, to construct all the parts of an horological machine so, that the arc of vibration may vary as little as possible under the different influences that affect the pendulum's motion; for then, whatever the length of the arc be, whilst there is no variation in it, the vibrations will be isochronal, whatever be the nature of the curve; but completely to effect so desirable a purpose can hardly be expected under all the combinations of variable resistances arising from friction, oil, air, &c., however detached the escapements may be, *i.e.* however small the continuance of each of their impulsions. Hence, certain ingenious artists have attempted such a compound scale of forces, consisting of gravity and maintaining power conjointly, as shall render even circular vibrations of different lengths isochronal among themselves, when they shall happen to vary in length, which plan would certainly make the best compensation for the effects of variable resistances, if such plan could be completely executed at pleasure; and the compound scale of forces to do this, must be to the scale of gravity alone, as the arc of semi-vibration is to the sine of the same in every point of the excursions. For in *fig. 1*, if  $BF$  be supposed equal to the semi-arc  $BD$ , then  $BE$ , the whole compound force at the point  $B$ , will be greater than  $CB$  or force of gravity alone, and will be to it, by similar triangles, as  $BF (= BD)$ , is to the sine

$AB$ , as has been demonstrated; therefore the whole compound force at any point  $B$  of either semi-vibration should be to the force of gravity alone in that point, as the arc  $DB$  is to the sine  $AB$ , which compound scale consequently will demand a certain limited variation, or scale, in the auxiliary force derived from the maintaining power through the modifying medium of the escapement.

2. When a balance was first applied as a regulating power, it possessed no natural property, like the pendulum, of perpetuating its own oscillations, but had its motion produced by an artificial force acting alternately on its opposite pallets, and derived entirely from the maintaining power at certain intervals; so that to perform all the oscillations in equal times, the action of the force applied was required to be the same in mode, quantity, and duration, in each oscillation, which conditions could not be fulfilled by reason of the constant changes that took place in the friction of the works, and in the density and consequent resistance of the air; a simple balance therefore was no otherwise better than a continued fly, except that its alternate oscillations prevented the acceleration of motion that would ensue, if there were no such frequent checks as the balance experiences at each alternate impulse of the pallets. Dr. Hooke's invention of a regulating spring, to be to the natural balance what gravity is to a pendulum, was an important one, to which all the excellence of an ordinary watch may have its origin imputed, and without which the compensations for different temperatures in the best chronometers would not be of any utility. The discovery of a *spring's force* being *as its tension*, or distance moved from the point of rest, (*ut tensio sic vis*,) was the first step towards a theory of motion by which the balance and its regulating spring, taken conjointly, may have their effect estimated, and by which such a balance with the best compensation and escapement now vies in accuracy even with the pendulum itself.—George Atwood, esq. of Cambridge, has published an excellent memoir in the Philosophical Transactions of London, vol. 84, part i. 1794, intitled "Investigations founded on the Theory of motion, for determining the times of Vibration of Watch Balances," from which we beg leave to extract so much as falls within our purpose in this place.

"Let  $PMNS$ , *fig. 3*. of our last plate, represent the circumference of a watch balance, which vibrates by the action of a spiral (or helical) spring, on an axis passing through the centre  $C$ . Let  $ODBE$  be the circumference of a concentric circle, considered as fixed, to which the motion of the balance may be referred. In the circumference of this circle let any point  $O$  be assumed, and when the balance is in its quiescent position, suppose a line to be drawn through  $C$  and  $O$ , intersecting the circumference of the balance in the point  $A$ ; the radius  $CA$  will be an index, by which the position of the balance, and its motion through any different arcs of vibration, will be truly defined. In the sequel, the motion of the balance, and the motion of the index  $CA$ , will be used indifferently, as terms conveying the same meaning. Since the balance is in its quiescent position when the index  $CA$  is directed to the fixed point  $O$ , on this account  $O$  is called the point of quiescence of the balance, or balance spring, indicating the position when the balance is not impelled by the spring's elastic force either in one direction or the other. If the balance should be turned through any angle  $OCB$ , the spiral spring being wound through the same angle, endeavours by its elastic force to restore itself, and when at liberty, impels the balance through the arc  $BO$  with an accelerated velocity, till it arrives at the position  $O$ , where the force of acceleration ceases; with the velocity,

## ESCAPEMENT.

city acquired at O, the balance proceeds in its vibration, describing the arc OE with a retarded motion. The elastic forces of the spring at equal distances, on the opposite sides of the point O, are assumed to be equal; it is also assumed that the effects of friction, and other irregular resistances, which retard the motion of the balance, are compensated by the maintaining power, so that the time of describing the first arc of vibration BO, by an accelerated motion, shall be equal to the time of describing the latter arc OE, by a retarded motion, and that the entire arc of vibration BOE is bisected by the point O.

To render the construction of *fig. 3.* more distinct, the fixed circle ODBE is represented to be at a small distance from the circumference of the balance, but is to be considered as coincident with it, so that the arc BO, subtending the angle BCO, may be of the same length with an arc of the circumference of the balance, which subtends the same angle BCO: on this principle CO or CA may be taken indifferently as the radius of the balance.

The determination of the time in which the balance vibrates, from the theory of motion, requires the following particulars to be known, *viz.*

First. The spring's elastic force, which impels the circumference of the balance, when it is at a given angular distance OD, (*fig. 3.*) from the quiescent point O:

Secondly. The law or ratio observed in the variation of the spring's force, while the balance is impelled from the extremity of the semi-arc B, to the point of quiescence O, where all acceleration ceases.

Thirdly. The weight of the balance, including the parts which vibrate with it.

Fourthly. The radius of the balance CO, and the distance of the centre of gyration from the axis of motion CG.

Fifthly. The length of the semi-arc BO.

Suppose the plane of the balance to be placed vertically, and let a weight P, (*fig. 4.*) be applied by means of a line suspended freely from the circumference at T, to counterpoise the elastic force of the spring when the balance is wound through an angle from quiescence OCD. This weight P (the weight of the line being allowed for,) will be the force of the spiral (or other) spring, which impels the circumference of the balance, either at rest or in motion, when at the angular distance OD from the quiescent position. It appears from many experiments (of Berthoud) that the weights necessary to counterpoise a small spring's elastic force, when the balance is wound to the several distances from the quiescent point, represented by the arcs OG, OH, OI, &c. *fig. 4.* are nearly in the ratio of those several arcs. It also appears, that the shape, the length, and number of turns of the spiral, may be so adjusted to each other, that the forces of elasticity shall be counterpoised by weights, which are in the precise ratio of the angular distances from the quiescent position, or, as it is sometimes expressed, in the ratio of the spring's tensions; at least as nearly as can be ascertained by experiment: this law of elastic force is assumed in the subsequent investigation.

The position of the centre of gyration may be always determined when the figure of the vibrating body is regular, by calculating the sum of the products, which arise from multiplying each particle into the square of its distance from the axis of motion, and dividing the sum by the weight of the vibrating body; the square root of the result will be the distance of the centre of gyration from the axis of motion. When the figure of a vibrating body is irregular, recourse must be had to experimental methods, in order to

determine the position of the centre of gyration. See Atwood's treatise "On the Rectilinear Motion and Rotation of Bodies."

Let the radius of the balance CA or CO =  $r$ , *fig. 3.* the semi-arc BO =  $b$ ; let the spring's elastic force, acting on the circumference of the balance, when wound to any given angle OCD, from the quiescent position, be P, and let the arc OD =  $a$ ; the weight of the balance and the parts which vibrate with it =  $W$ ; the distance of the centre of gyration from the axis of motion CG =  $g$ . These notations being premised, the resistance of inertia, by which the mass contained in the balance opposes the communication of motion to the circumference, is  $\frac{Wg^2}{r^2}$ ,

and consequently the force which accelerates the circumference at the angular distance OCD from the quiescent position is  $\frac{Pr^2}{Wg}$ . This quantity remaining invariably the same, while the balance describes the arc of vibration BOE, may be denoted by the letter F, so that  $F = \frac{Pr^2}{Wg}$ ; suppose

the radius CA commencing a vibration from the point B to have described the arc BH, and let OH =  $x$ , since the force which accelerates the circumference at the angular distance from quiescence OD = F, and the forces of acceleration are supposed to vary in the proportion of the angular distances from the quiescent point O, the force which accelerates the circumference of the balance at the point

H will be =  $\frac{Fx}{a}$ ; let  $u$  be the space through which a body

falls freely from rest by the acceleration of gravity, to acquire the velocity of the circumference at the point H; the principles of acceleration give this equation  $u =$

$\frac{-Fx\dot{x}}{a}$ ; (Newtonii Princip. vol. i. prop. xxxix.) and

taking the fluents while  $x$  decreases from  $b$  to  $x$ ,  $u = \frac{F \times b - x^2}{2a}$ ; if therefore  $l$  is made = 193 inches, being the

space which bodies falling freely from rest by the force of gravity near the earth's surface describe in one second of time, the velocity of the circumference, when the extremity A of the index CA has arrived at the point H,

will be =  $\sqrt{\frac{2lF}{a} \times \sqrt{b^2 - x^2}}$ . Let  $t$  represent the time in which the circumference describes the arc BH; then

will  $t = \sqrt{\frac{a}{2lF} \times \frac{-\dot{x}}{\sqrt{b^2 - x^2}}}$ ; and  $t = \sqrt{\frac{a}{2lF} \times a}$

circular arc, of which the cosine =  $\frac{x}{b}$  to radius = 1, which

is the time of describing the arc BH expressed in parts of a second; when  $x = 0$ , that is, when the circumference has described the entire semi-arc BO, the circular arc of which

the cosine =  $\frac{x}{b}$  is a quadrant of a circle to radius = 1. Let

$p = 3.14159$ , &c. the time  $t$  of describing the semi-arc

BO =  $\sqrt{\frac{a}{2lF} \times \frac{p}{2}} = \sqrt{\frac{p^2 a}{8lF}}$ .

In this expression for the time of a semi-vibration, the letter  $a$  denotes the length of the arc OD (*fig. 3.*); if this arc should be expressed by a number of degrees  $c^\circ$ ,  $a$

will then =  $\frac{prc^\circ}{180}$ ; and this quantity being substituted for

$a$ , the

# ESCAPEMENT.

$t$ , the time of a semi-vibration will be  $t = \sqrt{\frac{p' r c^2}{8 l F \times 180^2}}$ ;

if instead of  $F$ , its value  $\frac{P r^2}{W g}$  is substituted in the equa-

tion  $t = \sqrt{\frac{p r c}{8 l F \times 180}}$ , the time of a semi-vibration will

be  $t = \sqrt{\frac{W p g^2 c}{8 P r l \times 180^2}}$ .

Let the given arc  $c'$  be  $= 90$ ; in this case  $t = \sqrt{\frac{W p g^2 c^2}{16 P r l}}$ .

These are expressions for the time of a semi-vibration, whatever may be the figure of the balance, the other conditions remaining the same as they have been above stated. If the balance should be a cylindrical plate, it is known that the distance of the centre of gyration from the axis is to the radius as 1 to  $\sqrt{2}$ ; wherefore in this case  $g^2 = \frac{c^2}{2}$ ; and the time of a semi-vibration, or  $t = \sqrt{\frac{W p^2 r}{32 P l}}$ .

Agreeably to this expression, Mr. Atwood wished to try the practical results of a chronometer made by Kendal, to prove how far his theory agrees with practice, and assuming the centre of gyration to be the same as if the balance were a cylindrical plate, he obtained from Mr. Earnshaw the following data, *viz.*

- $W$ , the weight of the balance and vibrating parts = 42 grains.
  - $P$ , the force at the circumference of the balance, which counterpoises the force of the spring when wound to the distance of  $90^\circ = 24$  grains.
  - $r$ , the radius of the balance = 1.125 inches.
  - $l$ , the space described in one second of time by bodies which descend freely from rest by the acceleration of gravity = 193 inches.
  - $p$ , the circumference of a circle to radius 1 = 3.14159, &c.
- The balance, when adjusted to mean time, made just five vibrations in a second; the actual time of a semi-vibration is therefore 0.1000.

Then  $t$ , the time of a semi-vibration by the theory, will be  $= \sqrt{\frac{42 \times 3.14159^2 \times 1.125}{32 \times 24 \times 193}} = 0.0994$  parts of a second; hence  $0.1000 - 0.0994 = 0.0006$  is the difference between the actual time and the time by calculation from the theory; and the near coincidence of the two results proves that the supposition of the centre of gyration being nearly as in a cylindrical plate, is near the truth.

"It is observable," says our author, "that the semi-arc of vibration  $BO = b$ , does not enter into these expressions for the time of a semi-vibration; if, therefore, instead of the semi-arc  $BO$ , an arc of any other length  $LO$ , terminating in the point of quiescence, (*fig. 3.*) should be substituted in the preceding investigation, the time of describing  $LO$  would be

still  $= \sqrt{\frac{a p^2}{8 l F}}$ , or,  $\sqrt{\frac{p' r c^2}{8 l F \times 180^2}}$ , equal to the time

of describing the other semi-arc  $BO$ ; consequently, whether the balance vibrates in the largest or smallest arcs, the times of vibration will be the same. From the preceding investigations it appears, continues our author, that when the force by which the circumference of the balance is accelerated at the given angular distance  $c^\circ$  from the quiescent position is  $= F$ , the time of a semi-vibration  $t =$

$\sqrt{\frac{p' r c^2}{8 l F \times 180^2}}$ ; and conversely, when the time of a semi-

vibration is  $= t$ , the force which accelerates the circumference at the given angular distance  $c^\circ$  from the quiescent

position, that is,  $F = \sqrt{\frac{p' r c^2}{8 l t^2 \times 180^2}}$ .

"Since time-keepers are usually adjusted to mean time when the balance makes five vibrations in a second, the time of a semi-vibration will, in this case, be  $= \frac{1}{10}$ th part of a second; the substitution of  $\frac{1}{10}$ th for  $t$  being made in the preceding equation, the force which accelerates the circumference of the balance, when at any given angular distance  $c^\circ$  from the quiescent position, will be determined for all time-keepers adjusted to mean time, in which the balances make five vibrations in a second. Suppose the given angle  $c^\circ = 90^\circ$ , then making  $c^\circ = 90^\circ$ ,  $p = 3.14159$ , &c.  $l = 193$ ,  $t = \frac{1}{10}$ , the accelerative force at the angular distance from quiescence

$90^\circ$  or  $F = \frac{p' r 90^2}{8 l t^2 \times 180^2} = r \times 1.00408926$ . We have

therefore arrived at the following conclusion; if the radius of the balance is equal to one inch, and the time-keeper is adjusted to mean time when the balance makes just five vibrations in a second, the force which accelerates the circumference of the balance at the distance of  $90^\circ$  from the quiescent position is  $= 1.00408926$ , the accelerative force of gravity being  $= 1$ . And if the radius of the balance is greater or less than one inch, the force by which the circumference is accelerated at the distance of  $90^\circ$  from quiescence will be greater or less than 1.00408926 in proportion to the radii.

"According to the principles assumed in the preceding solution, the spring's elastic force is supposed to vary in the proportion of the angular distances from the quiescent position, and on this condition the vibrations are shewn to be isochronous, whether they are performed in longer or shorter arcs; but if the spring's elastic force at different distances from quiescence should not be precisely in the ratio here assumed, the longer and shorter arcs may be described in times differing in any proportions of inequality. If, for instance, the spring's force, instead of varying in the ratio of the aforesaid distances, should vary in the  $\frac{1}{1000}$ th power or  $\frac{1}{800}$ th power of the distances, it does not appear from the preceding solution what alteration in the daily rate would be caused by this change in the law of the force's variation, when the semi-arc of vibration is increased or diminished by a given arc. To ascertain this point fully, other researches will be necessary, by which it may be known, what alteration of the daily rate of a time-keeper is occasioned by a given increase or diminution of the arc of vibration, when the spring's elastic force varies in a ratio of the distances from the quiescent position, the general index or exponent of which is any number or fraction  $n$ .

"The force which accelerates the balance being assumed in that power of the distances, the exponent of which is  $n$ , let  $BO = b$ , (*fig. 5.*) be the semi-arc of vibration when the time-keeper is adjusted to mean time; let  $DO = a$ ; the accelerating force on the circumference at the distance from quiescence  $OD = F$ ; suppose the circumference to have described the arc  $BH$  from the extremity of the arc  $B$ ; and let  $HO = x$ : then the force by which the circumference is accelerated when at the angular distance from

the quiescent position  $OH = \frac{F x^n}{a^n}$ ; let  $u$  be the space

through which a body falls freely from rest by the acceleration of gravity, to acquire the velocity of the circumference when it has described the arc  $BH$ : the principles of acceleration gave this equation  $u = \frac{-F x^n \dot{x}}{a^n}$ : taking the flu-

# ESCAPEMENT.

ents while  $x$  decreases from  $b$  to  $a$ ,  $u = \frac{Fl^{n+1} - Fa^{n+1}}{n+1 \times a^n}$ , and  $l$  being 193 inches, the velocity acquired by the circumference, after describing BH; will be  $= \sqrt{\frac{4lF}{n+1 \times a^n}} \times$

$\sqrt{b^{n+1} - a^{n+1}}$ ; let  $T$  be the time of describing the arc BH; wherefore  $T = \sqrt{\frac{n+1 \times a^n}{4lF}} \times \frac{-\dot{x}}{\sqrt{b^{n+1} - a^{n+1}}}$ .

The time of describing the arc BH will be the fluent of this fluxion, while  $x$  decreases from  $b$  to  $a$ , and the time of describing the semi-arc BO will be the entire fluent of

$\sqrt{\frac{n+1 \times a^n}{4lF}} \times \frac{-\dot{x}}{\sqrt{b^{n+1} - a^{n+1}}}$ , while  $x$  decreases

from  $b$  to  $a$ . Now let the balance commence its vibration from any other point I, (fig. 5.) and let IO =  $c$ ; suppose the circumference to have described the arc IK, and make OK =  $y$ ; let  $t$  be the time of describing the arc IK; then by proceeding in the same manner as in the former case, it is

found that  $t = \sqrt{\frac{n+1 \times a^n}{4lF}} \times \frac{-\dot{y}}{\sqrt{c^{n+1} - y^{n+1}}}$ ; and

the time of describing the semi arc IO will be the entire fluent of this fluxion, while  $y$  decreases from  $c$  to  $a$ . Al-

though the fluents of the fluxions  $\frac{-\dot{x}}{\sqrt{b^{n+1} - a^{n+1}}}$ , and

$\frac{-\dot{y}}{\sqrt{c^{n+1} - y^{n+1}}}$ , cannot be expressed in general terms,

yet the exact proportion of the said fluents may be assigned, which will be the proportion of the times in which the balance vibrates in the two semi-arcs BO, IO; the multiply-

ing quantity  $\sqrt{\frac{n+1 \times a^n}{4lF}}$  being common to both fluxions;

and since the entire fluent of  $\frac{-\dot{x}}{\sqrt{b^{n+1} - a^{n+1}}}$  is to the en-

tire fluent of  $\frac{-\dot{y}}{\sqrt{c^{n+1} - y^{n+1}}}$  as  $b \frac{1-n}{2}$  is to  $c \frac{1-n}{2}$ ,

it follows that the time of a semi-vibration in the arc BO is to the time of a semi-vibration in the arc IO

as  $b \frac{1-n}{2}$  to  $c \frac{1-n}{2}$ , or as 1 to  $\frac{IO}{BO} \frac{1-n}{2}$ .

Suppose a watch to be adjusted to mean time when the semi-arc of the balance's vibration is = BO, (fig. 5.) and let this semi-arc be afterwards diminished to IO; the time shewn by the watch in any given portion of mean time  $t$ , when the semi-arc of vibration is IO, will be  $= t \times \frac{BO}{IO} \frac{1-n}{2}$ ; and if  $t$  is put =  $24^h$ , the alteration of the

daily rate, in consequence of the diminution of the semi-arc of vibration from BO to IO, will be  $24^h \times \frac{BO}{IO} \frac{1-n}{2} - 1$ .

To apply this proposition, let a case be assumed; suppose a watch to be regulated to mean time, when the semi-arc of vibration is  $135^\circ$ , and let this semi-arc be diminished  $8^\circ$ , so as to become  $127^\circ$ ; let the ratio of the spring's elastic force deviate from that of the distances from the quiescent position by a small difference of  $\frac{1}{10000}$ th power of the distances, instead of in the entire ratio of the said distances from the quiescent position. The alteration in the daily rate of the

watch will be obtained from the preceding theorem, by making the following substitutions; BO =  $135^\circ$ ; IO =  $127^\circ$ ,  $n = 10000$ , the alteration of the daily rate =  $24^h \times \frac{135}{127} \frac{1}{10000} - 1 = + 2''.62$ ."

From this theory of the balance and balance spring it is evident, that when there is a very minute alteration in the law of the force's variation, amounting to no more than  $\frac{1}{10000}$ th part of the entire ratio of the distances, an acceleration is caused in the daily rate of more than  $2\frac{1}{2}''$ , when the diminution of the semi-arc is only  $8^\circ$ , and as this alteration in the force is less, probably, than can be detected by actual measurement of the force by mechanical means, it is very probable that a much greater acceleration or retardation of the rate, than in the example before us, may occur from the same cause, which can only be corrected by a corresponding alteration either in the length or strength of the balance spring, or both, as the case may require, and the best way of detecting the law of force by which the spring acts at different distances from the quiescent position, is by increasing or diminishing the maintaining power, so as to render the arc of vibration unequal in successive trials for a limited time. The necessary conclusion, from such trials with different maintaining powers, will be, that when an acceleration of the daily rate accompanies a diminution of the arc of vibration, the elastic force of the spring used varies in a less ratio than that of the distances from the quiescent position; but on the contrary, when a retardation takes place under the same circumstances, the said elastic force varies in a higher ratio than that of the distances from the point of quiescence. We here suppose the same escapement to be used in all the trials, and that the impulse given to the balance is no more than sufficient to overcome the inertia of the balance and the resistance it meets with from friction and the density of the air; but as there is generally an overplus of power communicated to the balance to guard against stopping by the accession of dirt or thickening of the oil, this superfluous power has such an influence on the balance and its spring when in motion, as to produce a compound law of varying forces, somewhat different from the simple law derived solely from the elasticity of the spring, and the more this compound law varies from the simple law derived from the spring's elasticity, the greater will be the discrepancy between the theory and performance of a watch balance. The business of a good escapement of a watch or balance clock is to keep the balance in continual motion with as little interference as possible with the simple law of its natural varying forces, which it has been shewn are in proportion to the distances from the point of quiescence.

After these remarks on the laws by which a pendulum and a balance together with its spring become the regulators of an horological machine, the reader will be able to form an opinion, founded on scientific principles, on the merits or demerits of the different escapements that are successively described, not only in this article, but in the articles CHRONOMETER and CLOCK, which have been already published.

Henry Sully, who was an ingenious clock and watch maker about the beginning of the 18th century, wrote a history of the escapements of his time down to the year 1727, which Julien le Roy added to Sully's "Regle Artificielle du Temps," in the second edition, published at Paris, 1737, from which Berthoud has extracted his account of several escapements in his "Histoire de la Mesure du Temps," and which we mean to avail ourselves of in a certain degree in our subjoined descriptions.

## ESCAPEMENT.

The different escapements of clocks and watches may be divided into four classes; *viz*;

1. Those with a *recoil*; or which produce a backward motion of the escapement wheel and second's hand in some parts of the vibration; (échappement a recul.)

2dly. Those that have the *dead-beat*, or that allow the escapement wheel and hand to rest while the whole vibration is made; (échappement a repos.)

3dly. *Detached*, or *free* escapements, which act on the balance or pendulum an almost insensible time, and suffer the vibration to be performed almost without connection with the pallets; (échappement a vibrations libres.)

4thly. *Detached*, or *free* escapements with a *remontoir*, or auxiliary spring frequently wound up by the maintaining power, to equalise the arcs of vibration; (échappement a vibrations libres et a remontoir d'égalité d'arcs.)

The most ancient escapement in use at this time, and probably the first that was ever contrived, is the *crown-wheel escapement* at present employed in our table-clocks and common watches; we know not who was the original inventor, but find mention made of it by Leonard de Vinci, who died in the year 1513; and Venturi thinks that the horological machines of Wallingford and Dondi, early in the fourteenth century, had the same, as we have seen, under our article *CLOCK*, that Henry de Wyck's clock had in the year 1364. The idea of converting a rotatory into a vibratory motion, and the means adapted to effect this purpose mechanically are equally ingenious; as an effort of genius this thought is much to be admired. We have already given a general description of the connection that the escapement-wheel has with a train of wheel-work on one side of it, and with the balance on the other, under our article just referred to, but as the balance had no rim, and was without the *regulating*, or, as it is sometimes called, the *pendulum spring*, we think it right to give a separate drawing and description of this escapement, as made at present, together with some remarks on its properties.

1. *Crown-wheel escapement*.—In *Plate XXXI. of Horology*, *fig. 6.* represents the crown-wheel and balance in connection, which may be in either a horizontal or vertical position, and is in fact sometimes in one position and sometimes in the other in a common watch agreeably to the different positions of the body of the wearer; and it is easy to conceive that a short pendulum might be substituted for the balance when the crown-wheel moves horizontally in a fixed position, and the axis of the balance is placed horizontally, which is the case in most of the portable clocks. The name of crown-wheel is taken, no doubt, from the resemblance it has to an old fashioned *royal diadem*; but when applied to a watch it is frequently called simply the *balance-wheel*, from its connection with the *balance*: this wheel and the balance, including the pallets and regulating spring, may be considered as constituting the *escapement*, the action of all which may be understood from the following short account.

Suppose the pinion *a*, on the arbor *ab* of the balance-wheel or crown wheel *cd*, to be actuated by the main-spring, or weight which forms the maintaining power, by means of the ratchet, in the direction *efdc*, while the pallets *e* and *f*, attached to the axis of the balance *gb*, and standing at right angles to each other, or very nearly so, are long enough to all in the way of the ends of the sloped teeth of the wheel, when turned round an angle of 45°, so as to point in opposite directions, as in the figure; then a tooth of the wheel below, for instance, meets with the pallet *f*, supposed to be at rest, and drives it before it a certain space, till the end

of the tooth *escapes*; in the mean time the balance attached to the axis of the pallets moves in the direction *blg*, and winds up the small spiral spring *i*, one end of which is fast to the axis and the other to a stud on the plate of the frame, in this operation the spring opposes the momentum given to the balance by this push of the pallet *f*, and prevents the balance from going quite round before the pallet *e* meets with another tooth at the opposite end of the wheel's diameter; here this pallet receives a push which carries the balance back again, having as yet but small momentum, in the direction *blg*, and aids the spring, which now unbends itself till it comes to its quiescent position, but beyond that point is unwound, partly by the push from the maintaining power on the pallet *e*, and partly by the acquired momentum of the moving balance, particularly when this pallet has escaped; at length pallet *f* again meets with the succeeding tooth, and is carried *backward* by it, in the direction the balance is now moving in, till the maintaining power and force of the unwound spring together overcome the momentum of the balance; during which time the *recoil* of the second's hand is apparent, when put on the pivot of the arbor *ab*; at length the wheel brings the pallet *f* back again till it escapes, and the same process takes place with pallet *e* that has been described with respect to pallet *f*, and thus two contrary excursions, or oscillations of the balance, take place before one tooth has completely escaped, which is the reason why there must be always an odd number of teeth in this wheel, that a space at one side of the wheel may always be opposite to a tooth at the other, in order that one pallet may be out of action while the other is in action. The same account will apply to the vibrations of a short pendulum substituted for the balance, when this escapement is used. This escapement, which is of the first class, is evidently calculated to derange the natural law of the spring's varying force, which, we have seen, is in theory in proportion to the distances from the quiescent position; for as the action of the maintaining power continues to press on the pallets, either with or against the balance's motion, during a large portion of each vibration, this extraneous force acting along with the elastic force of the spring makes a new law compounded of the two forces, which may or may not be a regular law, as modified by circumstances, that are to be taken into consideration; for instance, the relative forces of the maintaining power and of the regulating spring, the uniformity of each force separately considered, the ratio between the radius of the pallet-wheel and length of the pallets, the weight and diameter of the balance, the angle of action in the escapement relatively to the whole arc of vibration, the adjustment of the length and strength of the spring for isochronism, and of its quiescent place to the position of the pallets, together with the friction and inertia of the acting parts, as well as resistance of the air to the moving balance must all enter into the account, which complex data render all calculations founded in theory very inadequate to their purpose of determining the practical results independently of experimental trials, which are necessarily adopted by the workmen in finishing the adjustments. The bad effect of an almost constant force on the balance, as derived from the maintaining power, is evident by the application of the key to the fusee-arbor of a watch, and by urging it in a direction contrary to that of winding up, for the additional force thus given to the maintaining power, will very sensibly accelerate the beats of the watch, and lessen the arc of vibration; hence any inequality occasioned in the maintaining power, by the accession of dirt, or by want of perfect compensation in the fusee of the varying force of the main-spring, &c. will alter the daily rate very materially, though the mechanical

## ESCAPEMENT.

mechanical adjustments at the balance may, in the first instance, have produced jointly a law of varying forces in the regulating mechanism that shall approximate near enough to the isochronous law of the balance spring, while the arcs of vibration remain unaltered. It is of the utmost importance, therefore, when a crown-wheel escapement is used in any watch, that, whenever a new main-spring is put in, the fusee should also be altered, so as to become as perfect a compensator as possible for that *identical spring*, which, we believe, is seldom, if ever, attended to in practice. This escapement usually has a pin in the rim of the balance that may catch a notch on each side of the cock beyond the extremities of the longest vibrations, called the *banking*, to prevent the derangement of the balance and of its regulating spring by any shake or accident.

2. *Escapement a pirouette by Huygens.*—About the year 1675, when Huygens was contriving the best construction he could devise of a marine time-piece, he naturally dwelt upon the portability of the balance, as affording the likeliest plan of accomplishing his purpose, but he was aware that the balance vibrating in short arcs was not comparable in point of steadiness to a pendulum, as a regulating principle, seeing it is too much under the controul of the maintaining power, when used with the crown-wheel escapement, the only one at that time known. The balance under such strong influence, and that a variable influence, had the property of putting itself into motion when in a state of rest: Huygens, therefore, made such additions to the balance and escapement then in use, as produced much longer vibrations than had been before witnessed, and introduced an additional wheel and pinion between the pallet-wheel and the balance to effect this object; thus, in *fig. 7.* of our last plate, is a side view of a small frame containing the mechanism of Huygens' escapement, consisting of two wheels, one pinion, a pair of pallets, and a balance with the spiral spring, together with the requisite cocks to bear the pivots of the arbors; *a b* is the crown-wheel or pallet-wheel of the usual shape and number of teeth, placed in a vertical position, like the contrate wheel of a common watch or table clock; *c d* is a contrate wheel placed horizontally, like the pallet-wheel of a common watch, having two pallets *e, f*, as usual on its arbor, at right angles to each other, and acting exactly as we have explained above; the contrate wheel *c d* drives a pinion *g* on the axis of the balance *h*, under which, as usual, is the spiral spring *i*; the action of this escapement differs from that of its predecessor only, inasmuch as the contrate wheel impels the pinion several times round at each impulse of one of the pallets, thereby occasioning several revolutions of the balance itself at each oscillation; and Sully says, that when the spring is not used he has seen the oscillations performed in the space of two seconds, and with a spring in one, in imitation of a seconds' pendulum clock, to which this escapement is not applicable. The influence, however, of the maintaining power must have been exerted on the balance in this construction also, during at least one of its revolutions, and the extraneous force interfering with the law of the spring's varying forces would produce a compound scale of forces, in which, as in the former instance, one would be nearly constant while it acted, and the other varying; besides, the friction in the teeth of the wheel and pinion, however well executed of the respective sizes and shapes, would produce checks that would be unfavourable to the steady oscillations of the balance, we therefore are not surpris'd to find that this escapement, which was of the first class, was soon discontinued.

3. *Escapement with two balances by Dr. Hooke, and by Du Tertre.*—Dr. Hooke, says Sully, produced a balance

in the year 1675, which he had invented in 1658, with two balances engaging each other by means of teeth cut in their edges, and one of them having a spiral spring on its verge or axis; but Berthoud attributes the invention of this escapement with two balances, without the spring, to a German artist on the authority of Thiout (*Traité d'Horlogerie de Thiout*) where there is a drawing of the escapement in question; J. B. Du Tertre afterwards made some additions, which we have given in *fig. 8.* of *Plate XXXI.*, and of which the following is a description, *viz.*; *A* and *B* are two balances acting together, like wheels with equal numbers of teeth, and having on one of the crosses of each a pallet, at *a* and *b* respectively; at equal distances from the axes of these balances is the arbor of the last wheel of the train, bearing two stars with each five radii, one numbered 1, 2, 3, &c. which is smaller than the other, lying the lower in position, and the other marked *d e f*, &c. with radii long enough to reach almost to the centres of motion of the balances, which they can pass only when the semi-circular parts that are cut away are presented to them; but at other times they rest against the central semi-circular pieces that remain uncut: the radii of the small star reach far enough to fall on the pallets *a* and *b* successively, which they impel alternately, and give motion to both balances at the same time; but the escape takes place by means of the radii of the large star, that rest successively against the semi-circular portions of metal not cut away, above the centres of the balances respectively. The three axes stand in the angles of an isosceles triangle, and have their upper pivots supported by three separate cocks, placed over the upper plate of the frame, the lower pivots of the balances resting on the upper plate, but the arbor of the two stars passing across the frame to take the last wheel. The action is thus; radius 1 of the small star has parted with the pallet *a* of balance *B*, and the long radius *d* is escaping; presently radius 4 will fall on the pallet *b* of balance *A*, and impel it in a direction from 4 to 5, the balance *B* at the same time moving in a contrary direction; this impulse will continue till the radius 4 falls from the pallet, soon after which the long radius *g* will fall on the semi-circular central piece of balance *A*, and stop the further motion of the two stars, which move together on the same arbor, and the balances will go on in their vibrations till the spring under balance *B* brings them back again, so as to present the cut half of the central piece of balance *A* to the point *g* of the long radius, which, being impelled by the train, now escapes; the stars go on till radius 4 of the small star meets with the pallet *a* of balance *B*, the motion of which it now opposes, and is itself brought back, so as to make a recoil of the hands till it has stopped the motion of the balances, which now begin each another oscillation: this radius 4 escapes the pallet *a*, and the long radius *g* falls on the semi-circular piece, at the centre of balance *B*, as it did before on that of balance *A*; the oscillation continues forward again till the spring brings it back, when another following radius of the small star falls again on the pallet *b* of balance *A*, as before, and drives it; soon after which a succeeding long radius falls on its semi-circular central piece, and rests till the return of the oscillation it can escape; thus an alternation of oscillations is produced by the short radii acting alternately on the two balances, while the long radii suspend the impulses by resting on the semi-circular parts of the centres of the balances, during the latter portion of each excursion. This escapement was evidently of the first class, like its predecessors, and though it avoided the jerk usually given to one balance by the stroke of the pallet, yet was subject to the friction arising from the action of the teeth, like the preceding

## ESCAPEMENT.

ing one; it had, however, a capability of making the angle of action and angle of the balance's motion before the escape in any ratio to each other, by altering the lengths or number of the radii respectively, as well as the distance of the pallets from the centres of motion; it had also the good property of preventing an increase in the maintaining power from affecting the balances in the same proportion, by the long lever pressing against the semi-circular central part of the balances alternately, during the latter part of the excursion of the balances, so as to check any accession of momentum occasioned by an accession of maintaining power: the law of this pressure, however, might be modified by changing the figure of the semi-circular piece into a spiral shape, so that the pressure might bear a proportion to the angular distances of the balances from the spring's quiescent position. The friction in both cases, it must be admitted, would be detrimental to the performance. The banking, we presume, in this escapement, was the same as in an ordinary watch, as no remark is made thereon. The invention, it appears, must be attributed to three successive artists; first the German, whoever he was, invented the escapement without the balance spring, and with the small star only, in which state it would act under the controul of the main-spring, without the regulating spring: secondly, the regulating spring was added by Dr. Hooke, and, thirdly, the large star was introduced by Jean Baptiste Du Tertre, about the year 1724, which addition completed the escapement as given in our drawing, which in its present state will not act without a regulating spring. Of course this last addition followed Tompion's and De Baufre's escapements hereafter described, from which probably the idea of the large star pressing on the circular part of the axis of motion was derived. Each addition was evidently an improvement on the original German escapement as described by Thiout; but the number of pivots in motion, and the increased friction occasioned by the pressure of the semi-cylindrical pieces at the centres of the balances, were obstacles too powerful to be overcome in this construction.

4. *First dead beat escapement by Tompion.*—The ingenious Tompion of London was probably the first watch-maker who contrived an escapement without recoil, or escapement of the second class, called a *dead-beat* escapement from the circumstance of the second's hand remaining motionless, or, as it were, dead, during the motion of the balance after the escape. Sully says that he succeeded in effecting this about the year 1695. In this escapement, of which *fig. 7. of Plate XXXV.* is a plan, the balance verge carried a cylindrical piece of metal *a b c*, terminating with a pallet *c*, with a notch cut between *a* and *c* to allow the escape of each successive tooth of the balance wheel. This wheel had its plane parallel to the planes of the plates of the frame, and its teeth bent at the end, and so distant, that the cylindrical piece and pallet could revolve between any two of them. When the cylindrical part of the pallet presented its notch to a contiguous tooth of the escapement wheel, it received a push therefrom, which put the balance in motion, and the next succeeding tooth falling on the circular or cylindrical portion of the pallet, now in motion in the direction *c b a*, rested against it without recoil till the balance spring had brought the notch back again, when it escaped in its turn by giving its push, and a third tooth fell on the cylindrical part of the pallet, and in like manner remained motionless till the notch came back again and allowed the escape: thus one escape took place at every alternate vibration, and the contrivance was admirably calculated to prevent the bad effect on the balance of any change in the impulses derived from the main-spring; but the friction on the back of the pallets when large, and at

the balance pivots occasioned by the pressure of the resting teeth, constituted the same objection in practice as applied to Du Tertre's modification of the escapement with two balances. This escapement, however, was the archetype of all the succeeding dead-beat escapements, and therefore is deserving of the notice we have given it.

5. *Cylinder escapement in diamond by De Baufre.*—A native of Geneva of the name of Facio had applied rubies to the pivot holes of a watch about the year 1700, and went into partnership with De Baufre, a French watch-maker, established in London; the latter artist finding the advantage of applying the polished surfaces of the precious stones for diminishing friction at the parts of action, contrived a new escapement about 1724, of which the pallets were of diamond. Sully says that a watch of De Baufre, with the diamond pallets, was put into his hands by sir Isaac Newton, who had found its accuracy of performance admirable. The following account will be intelligible, we presume, to any artist who understands the mechanism of a watch. The balance had two pallets on its verge consisting of a semi-cylindrical diamond, and the escapement wheels, of which there were two, were vertical, with their common arbor at right angles to the verge of the balance; *i. e.* with their planes parallel to the verge: these wheels, which were similar, were placed one opposite the other on contrary sides of the verge in such way, that a tooth of one fell in the middle of the space of the other, and *vice versa*; the pallets were  $\frac{1}{4}$ th of an inch thick, and two and a half twelfths in diameter, and the distance between the ends of the teeth of the double escapement wheel about  $\frac{1}{7}$ th of an inch, or twice as much as the thickness of the pallets; the pallets had their planes parallel to the plane of the balance, and had their semi-circle sloped in an angle of about  $45^\circ$  at the ends for the pallets to slide over, after pressing on their planes alternately during the respective oscillations. We will endeavour to explain the action, as we comprehend it to have been by a verbal description. Let the leading pallet be called *a*, and the following pallet *b*; and let the balance be supposed in motion with a tooth of the escapement wheel resting on the plane of the diamond; when the sloped end of pallet *a* arrives at the said tooth, the tooth falls off, accelerating the balance by its sliding motion, and goes on till an opposite tooth of the other wheel falls on the plane of the diamond in motion; this tooth rests without recoil, as did the former one, till the sloped end of the pallet *b* comes to it, when it falls off in its turn, and gives motion to the balance, which has thus its spring wound up by the momentum of the balance sufficiently far to bring the balance back again after every impulse; and thus an alternation of vibrations is continually maintained while the force of the mainspring lasts. This escapement is also of the second class, or of the dead-beat kind, but is subject to the constant friction of its immediate predecessors, though this friction is greatly diminished by the substitution of the diamond for metallic pallets, and by the bushing of the pivot holes with rubies; it possessed all the good properties of Tompion's escapement just described. (See *Machines and Inventions approuvées, &c.* vol. vii. p. 137.) Larcum Kendal used two crown wheels in a similar manner, which W. Howell improved by adding a forked detent to make the escapement detached, which was rewarded by the Adelpi Society, in 1792. See their *Transactions*, vol. x. p. 216.

6. *Sully's modification of De Baufre's escapement.*—The praise which sir Isaac Newton bestowed on De Baufre's new watch induced H. Sully to bestow much attention on it, and in the year 1721 he adopted an alteration in it, which made only one wheel necessary for the escape at both oscil-

lations;

## ESCAPEMENT.

lations; but Berthoud has expressed an opinion that his alteration constituted no real improvement, but made the adjustment of the pallets more difficult. Sully having applied his modification of the escapement in question both to a pendulum clock and a marine time-piece, presented two memoirs on its construction to the Royal Academy of Sciences in the years 1723 and 1724; which are also printed in his description of marine time-pieces, published in 1726. *Fig. 1. of Plate XXXII. of Horology*, represents a side view of this escapement, where A is the escapement wheel, B the contrate wheel between it and the balance C, which has a pinion only on its verge, that is actuated by the contrate wheel; the pallets 1, 2, are two circular pieces of agate, placed at the distance from one another of one space of the escapement wheel nearly; these pallets have each an inclined or sloped end, like De Baufre's, the slopes also being at the contrary ends of each; the intention of this modification is not only to make one wheel A perform the whole business of the escapes, but to produce long vibrations of the balance, even beyond a complete circle. The action was thus; on giving motion to the balance C, suppose the tooth *b* to rest on the plane of the pallet or agate 1, it soon meets with the end slope, and falls off till it meets with the pallet 2 below, on which it rests, after having given a push to the pallet during the act of sliding off; the balance goes on, till the spring, now wound up, brings it back, there being in the mean time no recoil, by reason of the arbor of the contrate wheel being also the axis of the pallets, and at right angles thereto; the tooth *b* now finds, after the return of the balance, the sloped end of pallet 2, and escapes entirely; but at the same instant tooth *c*, which follows, falls on the plane of pallet 1, and is then in the same situation we at first found *b* in, therefore the same action is repeated with this, and every succeeding tooth, till the power of the main-spring is exhausted. This modification of De Baufre's escapement is consequently of the second class also, and enables us to comprehend more clearly the action of the original one, which had its double escapement-wheel placed with respect to the balance verge, as the present one has its single one, with respect to the arbor of the contrate wheel. The effect produced must have been nearly the same on the pallets, though the vibrations of the original balance must necessarily have been shorter than of the latter, but then it had not the friction in the wheel-work between the pallets and balances.

7. *Escapement with two cylindrical pallets.*—In the year 1727 Julien le Roy shewed Sully some watches just brought from England into France, which had each two cylindrical pallets with notches cut in them like Tompion's single pallet, which kind of escapement seems to have differed from his, only in having an escape at every vibration, and in having the old crown-wheel as an escapement wheel; but as we have not been able to trace the inventor of this escapement, we must consider it as a lineal descendant from Tompion's, and therefore as a variety of English extraction. Its utility has been, however, evinced by the circumstance of Julien le Roy's having adopted it as a favourite, and used it in some of his productions: it had the property of converting the recoil of the crown-wheel into a dead-beat.

8. *Cylinder or horizontal escapement of Graham.*—We are not informed in what particular year Mr. Geo. Graham, the celebrated watch and clock-maker, invented the escapement with a cylinder, called also the horizontal escapement, from its wheel being in an horizontal position, but it appears that Julien le Roy introduced this construction into France in the year 1728, when wonderful properties were attributed to it, but particularly the property of compensating all the inequalities of the maintaining power, which at that time

was the great desideratum among watch-makers. The contrivance bears a great analogy to Tompion's escapement, and was probably originally derived from his, which, however, does not lessen the merit of the contrivance, as it requires as much ingenuity to improve an existing instrument, frequently, as to invent a new one. *Fig. 2. of Plate XXXII.* is a perspective view of Graham's horizontal escapement, in which A is the escapement-wheel, B the balance, and C the hollow cylinder fixed on the verge of the balance; each tooth of the wheel, which may have any convenient number of teeth, is formed of a triangular inclined plane or wedge, supported by a stem projecting perpendicularly from the plane of the wheel at its circumference; the length of the wedge of each tooth is just a diameter of the internal part of the cylinder, so that the cylinder may revolve round the wedge when the balance is in motion; in this situation the anterior point of the wedge just touches the cylinder's interior surface, but the posterior point of the same is free, so as not to touch and stick fast in the cylinder, but to give it a push on the edge when the contact ceases; the distance between the teeth is also great enough to allow the exterior portion of the cylinder to come between them, when the escape has taken place, and while the balance continues its oscillation. The action is performed in the following manner; suppose the wedge to be just escaping from the hollow part of the cylinder, and to be giving its impulse to the edge of the cylinder which it quits, the balance goes on and winds up the spring, as usual, at the same time presents its exterior face, or convex surface to the point of the succeeding tooth or wedge; this point falls on the said convex surface and rests there, without recoil, till the oscillation is finished, at the return of the balance, by means of the spring now wound up, the hollow or concave part of the cylinder comes to the point of this following wedge, and being rounded at this end, admits it easily into its concavity, at which instant the other edge of the cylinder receives a second impulse in a contrary direction; the balance now makes another oscillation; and the point of the wedge rests against the interior face of the cylinder, as it did before on the exterior, without recoil, and in both situations of rest the wedge has no other effect on the balance than that of retarding it by its pressure against the circular surface; the second tooth is now in the same situation as we found the first, and presently in its turn gives another push at leaving the cylinder altogether, and leaves the third wedge to perform the same office by first resting on the back of the cylinder, then entering it, and lastly giving its parting impulse to the second edge of the said cylinder, as the two wedges that preceded had successively done before. At one period this escapement was in high estimation in England, as well as on the continent, and even now the common watches that are constructed with this escapement will fetch greater prices than those with the ordinary crown-wheel escapement, but the detached escapements of the best chronometers are now held in much higher estimation than either. We have seen that the hollow cylinder, though constituting but one pallet, in effect performs the office of two pallets, and permits but one tooth or wedge to escape entirely at two oscillations, during one of which the point rests at the outside, and during the other at the inside of the cylinder, while the two edges of the cylinder perform the part of separate pallets on receiving separate impulses in contrary directions, it is, therefore, of importance in this, as indeed in all escapements with a regulating spring, that the quiescent position be duly adjusted to render both oscillations precisely similar in extent and duration at each side, otherwise the performance will be a species of hobbling, and the compound law of motion,

## ESCAPEMENT.

derived from the spring's action and impulses on the pallets conjointly, will be far from regular; consequently not likely to be an isochronal law. Berthoud has described a cylindrical escapement with two balances connected by two pinions, but it did not prove successful.

9. *French escapement a Virgule.*—The French escapement known by the appellation of a *virgule*, from the pallet's resemblance of a *comma*, is represented by *fig. 6* of *Plate XXXV.* A, B, C, are three teeth of the balance wheel, placed very obliquely compared to a true radial line, and carry each a pin at their extreme ends, standing vertically like the supports of Graham's wedges for his cylindrical escapement; the pallet B A has its centre of motion at *e*, the centre of both the concave and convex portion, exactly over the verge of the balance; this centre is in the circumference of the circle that passes through the points or pins of the teeth; the pallet, which is of hardened and polished steel, has its plane parallel to that of the wheel, and is supported between *f* and *e* by a crank piece put over the verge, which cannot be admitted as high as the pallet; this end *ao*, which connects the convex and concave portions, is a portion of an equi-angular spiral, and the part *bd* of the pallet is called the *horn*, probably from its resemblance of the beak of a bird; the inferior face *b A* may be straight like the dotted line, or curved, at the option of the maker, and the superior part *f A* may be of any shape: the convex part *a e f* contains about  $100^\circ$ . The length of the pallet from *a* to *d* is such, that when the pin at B presses against the curved part at *a*, the point *d* of the horn will just miss the pin at A of the preceding tooth, and the height at which the pallet stands is such as to make it pass over the rim of the wheel, but not over the pins at the ends of the teeth. When the balance is at rest, and has its spring in equilibrio, the point *d* of the horn is at the point *i*, about  $30^\circ$  from *d*; but the present position is that which the pallet has when the tooth A has just escaped from the point *d* of the horn. To explain the action, on a supposition that the tooth A has just escaped, the succeeding pin B has just fallen on the point *a*, joining the spiral and convex portions of the pallet, and the balance has just received its impulse from tooth A as it passed from *b* to *d* along the inferior face of the horn; it, therefore, proceeds in its motion in the direction *d g b* of the dotted circle, while the point B slides on the convex side *e f*, and is detained without recoil; when the point *d* of the horn has arrived as far as *h*, more than  $90^\circ$  from A, the momentum of the balance is exhausted, and the balance returns; the point *d* comes to about the point *i* before the pin of tooth B comes to *o*, and enters the concave part of the pallet, where it slides till the point arrives about *k*, where the momentum of the balance spring is again exhausted; the balance returns again, and when the point *d* comes to *i*, the pin of tooth B escapes the concave part at *b*, and slides along the inferior face of the horn, at the same time giving it a push till it escapes entirely, and is in the situation of tooth A, where the process began; in the same manner the following tooth C, and every succeeding tooth in its turn, will fall on the convex side of the pallet, return and enter the concave side, and then finally escape. We must observe, however, that the pallet opposes the motion of the balance as it passes along the small spiral part from *a* to *o*, which may be so proportioned as to be a counterbalance to the impulse previously given to the balance by the leading tooth, in case the friction on the back of the cylindrical part is not competent to retard the balance's impulse sufficiently. The effect produced by this escapement must be very similar to that produced by Graham's cylindrical escapement, but has this advantage, that the inclined plane formed on every wedge of Graham's construction is

transferred to the pallet; and serves for all the pins to slide on in succession, thereby removing the difficulty of forming all the wedges alike in size and shape. Besides, the convex and concave sides of the pallet may be reduced to any dimensions, provided the acting tooth may not slide at once from the spiral to the horn, and allow the train to run down, which may be the case if the parts of action be small, and there be much play in the pivot holes of the wheel and balance. The construction is a compound of Tompion's and Graham's watch escapements, to both of which it has certain points of resemblance. In 1752, Le Paute altered this escapement, by putting pins for teeth in both planes of the wheel, as he did in Amant's escapement a *cheville*, which addition gave it some advantages.

10. *Escapement with one pallet and one detent by Thiout.*—Thiout, a French clock-maker of considerable eminence, published a work in 1741, entitled "Traité de l'Horlogerie Mécanique et Pratique, approuvé par l'Académie Royale des Sciences," 2 vols. 4to, in which he has described an escapement of a watch that has been mistaken sometimes for a real detached escapement, and considered as the first that has been made of such a construction, though the inventor himself did not consider it as such, as is evident from his own description. This escapement is given in *fig. 8.* of *Plate XXXII.*, and to use the author's own account, "it is an escapement of a watch in which half of the vibrations *sem* independent of the train of wheels, while they are performed. The detent B stops the escapement wheel, the balance bringing back the pallet A, the detent recedes, to leave the wheel free to strike the pallet; and so on. This escapement could not perform without a spiral spring."—It hence appears, that the pallet A is on the verge of the balance, but that the detent B is on a separate arbor, while they are connected by the tail of the pallet entering the slit in the remote end of the detent, so that the balance is never disengaged from the detent, and therefore cannot be considered as of the detached class. When the balance moves in a direction from A to B the pallet gets out of the teeth, but the detent falls in, and *vice versa*. The curves of the claw of the detent appear to have been drawn from the centre of its motion, and therefore we are disposed to think that there would be no recoil in the escapement wheel.

11. *The anchor escapement by Clément, or Dr. Hooke.*—While these improvements were going on in watch escapements, an equal attention was paid to the contrivance of new clock-escapements. Huygens had placed the pallets of the crown-wheel escapement at an angle of about  $60^\circ$  instead of  $90^\circ$ , as they were made for a watch, in order that they might be accommodated to the short vibrations of a pendulum, or rather, perhaps, to the vibrations of some length performed in a cycloidal curve, by means of his cycloidal cheeks near the point of suspension; but still the arc of action on the pallets was too long to allow practice and theory to coincide, as to the performance of long and short arcs of vibration in the same time. The preference that seemed due to short arcs, when circular, suggested the propriety of contriving an escapement that would admit of very short arcs of vibration. This was first effected about the year 1680 according to Smith's account, by Clément, who was a clock-maker in London; but Dr. Hooke has disputed the priority of the invention, and has affirmed that he exhibited a pendulum with what is now known by the name of the *anchor* escapement, to the Royal Society of London, in the year 1666, soon after the great fire of that year. We will not endeavour to settle the point that relates to priority of invention, but proceed to describe the contrivance itself, which has continued, and is likely to continue, to be of permanent

use

## ESCAPEMENT.

nse in ordinary clocks. *Fig. 3.* of our last named plate is the representation of the anchor escapement, as it is commonly constructed for a pendulum clock that swings seconds, which pendulum, in conjunction with the anchor escapement, gained the appellation of the *Royal pendulum*. The escapement, or swing-wheel *A*, has usually thirty teeth, when a vibration is performed exactly in a second, in which case a second's hand is usually inserted on its elongated pivot, to indicate seconds; but if no attention is intended to be shewn to the indication of seconds, the train may be made to admit of any other convenient number of teeth; *B C* is the anchor and pallets, taking its name from a resemblance to a ship's anchor, that may be observed in its shape; the distance from its centre of motion *a* to that of the wheel *b* is determined by the number of teeth that the pallets take in between them, it being essential to the freedom of action that two lines, drawn from the two centres of motion *a* and *b*, should constitute a right angle at each of the two points of action, as seen included by the dotted lines, meeting at the ends of the acting teeth *d* and *e*: in the pallets which we have made to include nine teeth, the centre of the pallet's motion falls at the point *a*, but if they were made to include eleven teeth the said point would fall above at *h*; and if they included fewer than nine the point for the centre of motion would fall below *a*: in general ten or twelve are contained between the pallets of a second's pendulum, but this must depend on the arc that the pendulum is intended to vibrate; for the more teeth are taken in, the greater is the distance of the two centres of motion, and consequently the smaller the angle or arc of action on the pallets. If a circle *fg* be described by a radius equal to half the distance of the centres of motion *a b*, round the point *a*, the two faces of the pallets *B* and *C* usually lie in the tangent lines *ei* and *dg* of that circle, which lines are the guides for making the slopes. The action of the escapement before us may be explained thus; suppose the tooth *d*, seen resting on the slope of pallet *C*, to be urging this pallet outwards from the centre of the wheel, by which a motive force is applied to the moving pendulum through the medium of the crutch; presently it escapes, and pallet *B* is brought inwards towards *b*, so as just to avoid the tooth *e*; the wheel is now at liberty to move, and goes on, by the force of the maintaining power, till the succeeding tooth *k* falls on the sloped face of pallet *B*, which is now urged outwards, and endeavours to give a contrary motion to the pendulum; but the momentum of the moving pendulum is too powerful for its impulse, and carries the tooth *k* back again till the momentum is expended, at which instant a recoil of the wheel and second's hand placed on its arbor take place; presently the pendulum returns, and the tooth *k* now pushes it on, and escapes; the pallet *C* is now brought back, so that the tooth following *d* falls on its sloped face, and in its turn experiences a recoil till the pendulum returns, when it pushes on and escapes; then another tooth next after *k* falls on the face of *B*, and experiences the same recoil and subsequent power of escaping that the others did; and thus the alternate vibrations of the pendulum are perpetuated as long as the maintaining power continues. The effect of this escapement on the pendulum is similar to that of the crown-wheel escapement on the balance; the pendulum is either accelerated or retarded in every part of its vibration, except during the almost insensible instant of the drop of the succeeding tooth, when one has escaped; but as the momentum of a heavy pendulum in motion is greatly exceeding that of a balance in motion, the bad effect is smaller in degree. When an additional weight is added to the weight constituting the maintaining power, the arc of vibration is increased, whence one might be led to ex-

pect a retardation in the time of a vibration, the arcs being circular; but the fact is, that the vibration is accelerated very sensibly by means of the pendulum being both accelerated in its descent and opposed in its ascent, and the pendulum comes sooner back than gravity alone would bring it. Here then the compound law of motion differs from the simple law of gravity, but not in the ratio of the arcs to the sines of the angle of vibration; for if the compound law were to the simple law of gravity as the arcs are to their sines, the vibrations would be isochronal, whatever their extent might be. It is hardly necessary to add that this escapement is one of the first class.

12. *Graham's dead-beat.*—The dead-beat escapement, as originally contrived by Graham, is a modification of the anchor escapement we have just described, from which it differs only by taking off a part of the slope of each pallet, and by making the pads, that is, the back of one pallet and interior part of the other, portions of circles described from the anchor's centre of motion, so that when the point of a tooth rests on those parts, while the pendulum is finishing a vibration, no recoil takes place, but the wheel continues motionless, or, as it were, *dead*. *Fig. 4.* of the same plate gives the figure of the dead-beat escapement-wheel and pallets, where we have represented the wheel, as we did the wheel of recoil, with only four instead of six radii, that there might be more space for our geometrical lines. In this construction, as in the preceding one, the distance of the centres of motion *a, b*, is determined by the tangent lines meeting the radii at the points of the acting teeth; when this distance is an exact diameter of the escapement wheel, we find that the pallets take in just ten teeth out of thirty, which is the case in the figure before us, but when twelve teeth are taken in, the centre of the anchor's motion falls at *h*, just a diameter and a half from the centre of the wheel; and this is Berthoud's rule for giving the distance *a b* without any reference to the tangent and radius; for he has found that the arcs of action on the slopes of the pallets *a m n*, and *a o p*, are each only one degree, but that if fewer teeth than twelve were included between the pallets, the anchor would be shorter, and the arcs of action proportionally longer. This rule might be a good one with a given maintaining power, that is, where the whole arc of vibration is of a given extent, but it does not follow that one degree for the arc of action before the escape is the best in all cases where the motive powers vary. We are of opinion that experiments might be instituted to ascertain this important point, by applying various weights successively, first with pallets that have twelve teeth included, and then with such as have eleven, ten, &c. but the experiment could not go beyond 14 teeth, because when half the wheel is included the tangent becomes a vertical line, parallel to the line of distance *a b*, and therefore this distance becomes *infinite*. There is probably a certain maintaining power that is best for a certain angle of action, with a pendulum of a given weight, but that does not seem to have been ascertained either by calculation or experiment hitherto. The thing to be aimed at is, to make the compound law of the pendulum's motion such that the varying forces may accelerate or retard it in proportion to the arcs of distance from the lowest point, which is the case with the simple law of gravity, as it regards the sines of the said arcs. We have put the same letters of reference to our present figure as to *fig. 3.*, that the reader may the more easily comprehend the correspondence between them, and to prevent the necessity of further minute description of the parts; the slope of the pallets being determined by the same-tangent lines *ei* and *d g*, as before. We shall, therefore, confine the remainder

## ESCAPEMENT.

of our description to the features that differ, and to the mode of action depending thereon. The circle B C, passing the points of the first and eleventh teeth, including the ten spaces between the pallets, forms the interior faces of the said pallets B and C, and the exterior portions B e and C d are formed by a concentric circle of larger radius. These circles are described from the point a, or centre of the anchor's motion, therefore a tooth resting at any time against any one of those circular portions remains without recoil; the distance between the said circles is somewhat less than one-half of the space contained between the extreme ends of any two contiguous teeth, and the nearer it is to one-half of a space, the smaller will be the drop after an escape, or, as the workmen say, the closer the pallets will be laid. The teeth are somewhat varied in shape from the inclined teeth of the recoil escapement, a portion of the slope at the bottom being cut away, that the end of the pallet may enter the space, when the pendulum vibrates beyond the arc of action, without coming in contact with the metal of the wheel, which would make the pendulum rebound, and disturb the regularity of the vibration. These observations being premised, the reader will now be prepared to comprehend the action. The tooth at e has just passed the slope of pallet B, and is escaping, after having given its stroke or impulse gradually, in sliding along the slope from e to its present situation; the pallet B is now going from the centre of the wheel's motion b, and the pallet C is come back from its excursion, in time to allow the tooth b to fall on its inner circular part, near the angular point of the slope; the pendulum goes on in its vibration till its gravity overcomes its momentum, during which time, the pallet B is no longer in contact with the wheel, but the pallet C enters the space between b and d, and the point of the tooth b rests on the inner circle of the pallet; presently the pendulum returns, the point of tooth b slides back again till the slope b d presents itself, when urged by the maintaining power, it escapes after having made its push to the pallet C, which now continues its motion outwards, and consequently pallet B falls in the way of the tooth k, which follows, but which rests on the exterior circle B e of this pallet, till the pendulum returns as before; it then meets the slope at e, and, giving its push to the pallet, escapes, as its preceding tooth had done; and thus the vibrations are alternately aided in future, while, as has been seen, one tooth only completely escapes at the interval of two vibrations: which is the reason why a wheel of 30 teeth is proper for the indication of 60 vibrations of a second's pendulum. When the wheel is made of hardened steel, and the pallets of ruby or agate, the friction is greatly diminished, and will admit a short angle of action, or diminution of power.

13. *Modification of the dead beat by Grignon.*—When we gave the "History of the successive Improvements in Clocks," under our article CLOCK, we said that the senior Thomas Grignon, of Covent Garden, London, improved the dead-beat escapement of Graham, and presented a clock to the Society of Arts in 1759, which remains in one of their rooms to this day, that has got this improved escapement, the peculiar property of which is said to be, that it performed alike with *four* and with *twelve* pounds suspended as a maintaining power; if this is a fact, the escapement must have the property, so much desired in all escapements, of rendering all the arcs of vibration isochronal. We have been favoured with a manuscript account of this escapement, and of its principle of construction. It will be doing but justice to the memory of departed genius, if we give the author's own figures, demonstration, and account of his improvement, as he has left it in his own hand-writing. *Fig.*

5. of Plate XXXII. is the *scheme*, and *fig. 6.* the *demonstration*, as the author himself has intitled the figures, the latter of which has no letters of reference, but is sufficiently intelligible in conjunction with the other. "It appears from the scheme," says the author, "that the distance of the centre of the pallets from the centre of the swing wheel in that machine (at the Adelphi) is *one whole diameter* of the wheel, which has this peculiar excellence, that the triangles formed at the ends of the pallets, by drawing the tangents for the slopements are *equal*; (nor indeed can they ever be equal, continues he, where the distance is more or less than *one whole diameter* of the swing wheel,) and, on the contrary, where that distance is duly observed, all the triangles will ever be equal; for then all the interfections, made by drawing the two tangents to the circle of the pallets, will fall exactly alike, (*fig. 6.*) intersecting the intermediate circle, as may be seen by the figure, consequently the tangent lines, together with the chord of the swing wheel form a rectangled triangle, the upper angle of which, by altering the slopement only, changes its place in the circumference of the circle, the same chord always continuing its base. For a farther demonstration of which, see 21<sup>st</sup> proposition of the the 3<sup>d</sup> book of Euclid.

"Again, when the distance is duly observed, we shall find that one of the lines for the slopement of the pallets will be the hypotenuse, and the other the perpendicular of rectangled triangles, whose bases are equal to  $120^\circ$ , the halves of which must be  $60^\circ$ . That they are rectangled triangles may be easily proved; for if the base be  $120^\circ$ , and perpendicular  $60^\circ$ , the hypotenuse must be  $180^\circ$ . See 1<sup>st</sup> Prop. of the 12<sup>th</sup> book of Euclid."

In another manuscript paper, Mr. Grignon says, "that the teeth of the swing wheel have an equal effort, when they act upon the slopements or faces of the two levers or pallets, may be thus demonstrated.

"Draw the lines A, A, upon the faces or slopements of the pallets or levers a, a, now these are the lines of direction; let fall the perpendiculars B, B, from the centre of motion of the pallets C; now, I say, that if you measure the lengths of these perpendiculars, they give you the efforts of the arms of the levers or pallets D C, D C; for by the 9<sup>th</sup> prop. of Mr. De la Hire's Treatise of Mechanics, the efforts of a weight or power are not to be measured by the length of the arms of the levers, but by perpendiculars drawn from the hypomochlion upon the lines of direction of the weight or power. That these levers are equal is thus proved; for, taking C for your centre, describe the circle E E E; now if the perpendiculars B, B, are both radii of the circle E E E, they must, of consequence, be equal, which is what was to be proved. Again, that the faces or slopements of the pallets or levers are equal may also be thus proved: a A, a A, are the lines of direction of the action of the teeth, and being both tangents of the same circle E E E are consequently equal."

The remarks that have occurred to us on contemplating Mr. Grignon's *scheme*, as he has called it, are, first, that his distance between the centres of motion require *ten teeth* out of thirty to be taken in by his pallets, as we have shewn in our last article; secondly, the circle E E E is described with less than half the distance of the centres, and is yet made the circle to which the tangents are drawn, that form the slopes, the reason of which he has explained, the radius C B of this circle, it appears, must be determined by a line a A, drawn parallel to the line of distance, which must be a tangent to the said circle, and which affords an easy and practicable mode of drawing the slopes agreeably to this construction; thirdly, if the slopes thus formed by tangents

## ESCAPEMENT.

drawn to a diminished circle have the isochronal property, they are worthy of future imitation, under the circumstance particularly of ten teeth being included between the pallets; and lastly, we observe, that the *same circle* forms the exterior curve of one pallet, and the interior one of the other, which is not the case with Graham's pallets, but which certainly makes the friction alike on both pallets, seeing the circular surfaces rubbed by the points of the wheel's teeth are at equal distances from their common centre of motion. These considerations are all in favour of Mr. Grignon's modification of the dead-beat escapement, as each excursion of the pendulum must be influenced by similar circumstances, and if moreover it possesses the isochronal property attributed to it, it is somewhat remarkable, that the Adelphi society have been labouring to reward inferior escapements in great variety, while one of the best *dead-beat* escapements is beating *dead* to the society, having *escaped* their notice, while performing its functions within their own walls.

14. *Mr. Bennett's modification of the dead-beat.*—Mr. J. Bennett of Norwich has published an account of what he considers an improved method of describing the curves and faces of Graham's dead-beat pallets (see Nicholson's Jour. vol. xv. 8vo.) which account we think deserves a place here in common with Grignon's method.

Draw the line A B (*fig. 7. Plate XXXII.*) says the author, on which describe the circle B, the size of the intended swing wheel; then, according to the number of teeth the pallets are intended to escape over say, as 60 (the double of the number of the wheel's teeth) is to 360°, so is double the number intended and one more to that proportion; thus, suppose the number intended to escape over nine, the double of which is 18, to which add one, and there are 19; then say,

As 60 : 360° :: 19 : 114°; the half of 114°, which is the whole arc included, is 57°; then on the circle already drawn set off on each side of the line A B 57°, from which points draw lines to the centre of the circle; then on these points where the circle is crossed erect perpendiculars, which will intersect at the centre of the pallet's motion in the line A: from this point as a centre draw the arc C C, to cut the points where the radial lines cut the circle; the arc thus drawn describes the receiving and leaving pads of the pallets. The inclination or inclined plane of each pallet must form an angle of 60° with the said radial lines; thus from the points of intersection, near E and G, draw the small semi-circles D and G with any radius, and set off 60° from *f* to *g* on the semi-circle D, and from *b* to *m* on the semi-circle G, then will lines drawn from the centres of the semi-circles, through the points *g* and *m* respectively, give the proper direction of the slopes of the pallets' faces.

This construction is very similar to Grignon's, though differently projected: the centre of motion A is determined in the usual way, and the odd unit given to double the number of teeth included is an allowance for the breadth of the pallet, to have as little drop as possible; the slope of the pallet G is parallel to the line A B, in Grignon's construction, but is not quite so here, for the difference of the angles at the opposite sides of the radial line is  $60^\circ - 57^\circ = 3^\circ$ , which is what these lines want of being parallel, which quantity of deviation seems to constitute the principal difference between the two constructions; if the radial line of pallet G had been drawn to the lower point of the pallet, so as to have made the angle at the centre 60°, and the teeth included had been exactly ten, then the two methods would have coincided, and the point A of the pallets' motion would have been an exact diameter of the wheel from its centre.

We conceive that the effects of the two constructions may be so nearly alike, that their difference in practice may be almost imperceptible. If there is any difference, varying the maintaining power considerably in different trials will detect it, by rendering the alterations in the rates perceptible from the comparisons. Otherwise the alternate angles might each have been 57°, instead of one of them being 60°.

15. *Isochronal escapement for a pendulum.*—So long ago as about the year 1720 Saurin, Julien le Roy, and Enderlin, wrote memoirs on the nature of the curve that was necessary to give to the pallets of an anchor, instead of the concentric circles, in order that the swing wheel may have just so much recoil only, as will render all vibrations, performed in arcs of different extent, isochronal; and since their time Berthoud in France, Reid in Edinburgh, Melville and others in London, have put in practice a method of constructing pallets founded upon the same principle. We think it not improbable, however, but that the Scotch and English artificers have borrowed their contrivance from the French author, who published his construction in his "Essai sur l'Horlogerie" in the year 1786, before which time we do not find any traces of an isochronal escapement except Grignon's just described, and Smeaton's, which follows. The construction of the escapement in question differs from the dead-beat only in one particular, which is, that the circular portions of the pallets, which in the dead beat are concentric, described from the centre of the pallet's motion, in the isochronal escapement are *excentric*, with respect to each other, those curves on which the ends of the teeth of the swing wheel rest being described from points out of the centre of motion. Berthoud had made several experiments with different escapements, and different maintaining powers, from which he found that the same addition to the power which accelerated the vibrations of the pendulum, when a recoil escapement was used, retarded the same when a dead-beat escapement was substituted; hence he concluded that there must be a medium between much recoil and no recoil, which would make the pendulum vibrate in the same time in all arcs, or, which is the same thing, with any addition or diminution of the maintaining power; he therefore fixed, after various trials, on a construction producing but a *small recoil*, which answered his most sanguine expectations, and which we shall be happy to describe here, particularly as it promises to answer a better purpose than the common dead-beat, which has been long in high estimation; and as it has not, we believe, been described by any English author. *Fig. 1. of Plate XXXIII.* is a plan of Berthoud's isochronal escapement, where A, as before, is the swing-wheel, B and C the pallets of the anchor, and *a* the centre of their motion; the distance of the centres *a, b* also, as before, depending on the number of teeth taken in by the pallets; the angles *man* and *oap*, are the angles of action by which Berthoud has given his slopes of the pallets without the tangent lines *ei*, and *dg*, but we have thought it right to shew how they may be given both ways. Berthoud's method of sloping to suit any angle previously given is more extensive in its application, but the quantity and direction of the impulse will vary as the angles *man*, and *oap* vary; whereas the method of sloping by the tangent lines can only vary by varying the circle *fg*, as Grignon has proposed: in our plan we have taken the circle's diameter equal to the distance *ab* of the centres for the sake of uniformity of plan, that the reader may see how the pallets, so formed, differ in shape from the dead-beat pallets. The exterior portion of the circle *dC*, of pallet C, is described with the extent *ad* from the centre *a*, but the interior portion *b4* is described with the same extent from a point *4* below

## ESCAPEMENT.

below the centre; the difficulty consists in determining the true situation of this excentric point 5; Berthoud's rule, founded on the result of experiments, is this; having determined the breadth of the pallets, equal to somewhat less than half a space of the swing-wheel, describe from *b*, in the line *a p*, the concentric dotted circle 1, 2, 3, &c. set the distance between the two concentric circles, or breadth of the pallet, *three times* over along the inner curve to 1, 2, and 3, then in a direction from 3 towards *a* set the same *once* to 4; in the next place, with the extent *a b* find the point 5 by intersection from the points *b* and 4, and this point 5 is the excentric point desired, from which the curve *b 4* is described with the extent *a b* as before, which is the interior curve to be substituted for the concentric curve 1, 2, 3 of the dead-beat escapement; and it is evident that while the pendulum is in motion inwards, with a tooth resting on this excentric curve, the wheel must have a certain recoil. Again, the exterior curve of excentricity, of pallet B, is thus described; the curve 1, 2, 3, &c. is described, from the point of the tooth that is in the line *a m*, and the points therein are taken as before at the distance from each other of the breadth of the pallet, or at somewhat less than half a space of the wheel; the point 4 is here set outwards in the direction from *a* to 3; then with the extent *a e* the excentric point 6 is determined by intersection from *e* and 4, which point is above the centre; lastly, with the extent *a e*, as before, describe the excentric curve *e 4* from the point 6, which being substituted for the concentric circle 1, 2, and 3, will produce a similar recoil in the pallet B, as the curve *b 4* produces in pallet C. The inner curve of pallet B having no action, like the outer curve of pallet C, may be described from *a*, or be a straight line. The writer of this article has a half-second's pendulum clock with this escapement, and Troughton's tubular pendulum, which goes admirably with any power that will keep it in motion.

16. *Smeaton's escapement of the turret-clock at Greenwich.*—The escapement which Mr. Smeaton contrived for the turret clock at Greenwich resembles the isochronal escapement, which we have just described, in a certain degree, and was, no doubt, intended to answer the same purpose. *Fig. 2. of Plate XXXIII.* contains the plan of this escapement, in which *A B* is the radius of the escapement wheel; *BC* a tangent line at  $3\frac{3}{4}$  teeth from the vertex, drawn from *C*, the centre of the pallet's motion; *B D E* is a circle described from the centre *C* through the points *B* and *E*, which are each  $3\frac{3}{4}$  teeth from the vertex; *FG* is a line drawn parallel to the vertical line *A C* at the distance from the vertex of  $3\frac{1}{2}$  teeth, and cutting the circle *B D E* in the point *G*; then *G C B* is half of the angle of vibration, and setting off the arc *B H = B G*, *G C H* will be the whole angle of vibration. Draw the line *CH* cutting *FG* in *I*, and through the point *G* of this pallet from the centre *A* describe a circle that may cut the radius *A K* in the point *K*; this will be the point of the other pallet; the line *EC* being also a tangent to the wheel at  $3\frac{3}{4}$  teeth from the vertex. Now setting off *K L* on the circular arc = *GH*, the angle of vibration *K C L* will be equal to the other angle of vibration *G C H*, and if through the point *L* the line *CL* be produced, and *I M* be set off = *I H*, then will the wheel move equally forward, by a similar motion of each pallet. Again, with the radius *K C*, upon *K* as a centre, describe the arc *C N*, and also with the same radius from the point *M* describe the intersecting arc *O P*; then from *Q*, the point of intersection with the radius unaltered, describe the curve through the two points *K* and *M* to *R*, which curve will give the working face of the pallet that will produce a small recoil nearly equal to that produced by the plane *G I*; in this construction

the depth of the teeth is equal to a space contained between two contiguous teeth, and the acting side of the tooth is a portion of a circle described from the bottom of the sloped side of the *fifth tooth* inclusive. The circle to which the slope of the tooth is a tangent is  $\frac{1}{6}$ th of the diameter of the wheel. When the swing-wheel has a greater number of teeth than 30,  $7\frac{1}{4}$  teeth are still contained between the pallets, and the centre of their motion is determined, as in the former constructions, by a tangent line drawn from the point of the acting tooth. The two ends of the anchor may be made more apparently equal in length by letting the pallet *K* escape over  $3\frac{1}{4}$  teeth and the pallet *G* over  $4\frac{1}{4}$ , in which case the arc *B D* will be of a greater radius than the arc *N D*. The steel pallets or end-pieces are fixed by screws that allow an adjustment for distance or depth of the pallets, so that they may be detached, newly formed, and replaced, at any time after they have been in use.

17. *Escapement with two levers by De Bethune.*—Thiout says that De Bethune was the first contriver of the clock escapement with two detached levers, and that the origin of this construction was derived from the escapement of Dr. Hooke, or of a German artist, with two balances, which we have described. Thiout made the first of his in the year 1727, and says that from that time the escapement with two levers became common among clock makers in France. *Fig. 3.* of our last plate is a representation of this escapement as made for a pendulum; where *A* and *B* are the two levers placed fast on each a separate arbor included within the frame; to the lever *B* is attached the crutch or fork that communicates with the pendulum not seen, and the fork *C* which is visible in the figure; the lever *A* has a bar of metal *D* fast to it, that carries the roller *E*, of a diameter equal to the aperture of the fork *C*; and the ends of these levers constitute the pallets placed at the distance from each other of five out of thirty teeth of the swing wheel. During the action of this escapement, when one of the levers is acted on by a tooth, the roller and fork are raised up, and the other lever becomes a detent to the wheel; then when at the next vibration the other lever is acted upon, the roller and fork are depressed, and the first lever in its turn becomes a detent; and thus the vibrations are alternately assisted while the maintaining power continues to actuate the swing wheel. This escapement has a recoil, and Julien le Roy discovered (*Memoire sur l'Horlogerie par M. le Roy, fils aîné de Julien le Roy, 1750*) that when the levers are each the exact length of the radius of the swing wheel, it possesses the isochronal property, that is, all arcs of vibration will be performed with it in the same time. We are not aware that this escapement was ever made in England.

18. *Dead-beat escapement for a pendulum by Anant, (a cheville)*—*Fig. 4.* of the same plate shews the plan of an escapement by Anant, formerly a clock-maker at Paris, that has an escapement wheel without teeth, but with pins or pegs inserted in a concentric circle in the plane of the wheel, as appears in the figure; the pallets *A* and *B* are both fast to the verge or arbor of the crutch, in the usual way, and are brought so nearly together that the same pin that slides along the sloped face of one pallet *B* immediately falls on the inner circle of the other pallet *A*, and continues without recoil till the pendulum has made its vibration; at the return of the pendulum the pin meets with the sloped face of pallet *A* and escapes; then the next pin falls on the interior circle of pallet *B*, and remains without recoil till the pendulum returns from its vibration, when it slides down the slope and gives a push to the pallet as the first one did before; thus the two pallets are alternately actuated by the same pin before

## ESCAPEMENT.

its final escape, and sixty vibrations are made during one revolution of the plate with thirty pins. The slopes appear to stand at right angles to each other, but it is not said, in the account we have seen, how either of the slopes ought to be drawn geometrically. This is the kind of escapement at present used in the large turret clock at Hampton Court, and we have seen many other clocks in England with a similar escapement, which, we have no doubt, may perform as well as with the ordinary dead-beat escapement as originally constructed by Graham, provided the drop from the first to the second pallet, which must necessarily be equal to the thickness of the pin, do not produce a jerk that may affect the vibrating pendulum.

19. *Dead-beat escapement (a cheville) by J. A. le Paute.*—In Le Paute's "Traité d'Horlogerie," published at Paris in 1755, is an account of a dead-beat escapement as made by him for a clock, which differs from our last by Amant only in its mode of position, and which therefore requires no figure for its description; the levers of the two pallets open like a pair of dividers to any extent, but are not in the same plane, one of the levers being over the anterior plane of the pin wheel, and the other over the posterior plane; hence two sets of pins are necessary, one on each plane; but the action is the same as we have described it in Amant's escapement, which it probably excels inasmuch as the drop may here be made as little as possible, because the same pin is not required to pass between the ends of the pallets in escaping; but one pin acts only with one pallet before it escapes; there are consequently sixty pins in all, thirty on each plane of the wheel.

The same author also published an account of a watch escapement with pins (a cheville) which the reader will find described at page 198 of the same treatise.

It is easy to conceive, after what we have said about the isochronal pallets, that both Amant's and Le Paute's escapements, and indeed all the dead-beat escapements, may be made to have a little recoil, so as to become of the isochronal kind, provided the acting concentric circles of the pallets were made in a certain degree eccentric; that is, if they were described from points out of the centre of motion of the pallets themselves. The only difficulty is in determining the situation of those points under different circumstances, which we think is a fair object for future experiments.

20. *Harrison's clock escapement.*—The escapements which we have hitherto described require oil on the pallets, to diminish the friction of the parts that rub against one another in action; but the escapement we are now going to describe as the invention of the ingenious Harrison requires no oil, on account of his construction being free from rubbing at the time of the pallets' action. *Fig. 5. of Plate XXXIII.* exhibits the shape of Harrison's escapement. G D O is a portion of the flying wheel, moving round M as a centre: A is the verge or arbor of the crutch that communicates with the rod of the pendulum; to this are attached the pallets, each consisting of a long and a short lever with a joint at the place of union; the short lever A B is fast to the arbor or axis of motion, and carries the longer lever B C which has a claw or hook a C, and a slender spring is so applied as to keep these two levers nearly at right angles to each other; at right angles to A B is also the other short lever A E fast likewise to the axis of motion, and bearing the longer lever E F, as A B bears the lever B C; the joints are at B and E, and a similar small spring holds the levers A E and E F in like manner at right angles to each other, when not otherwise acted on. The lever E F has not only a claw, like the other long lever, but a heel to it; or projecting part f. The action of this contrivance may be thus

explained; suppose the tooth D urging the pallet or claw C, while the pendulum is moving towards the right hand in its excursion; this pressure of the tooth produces a tendency in the lever B C to move round, but the joint at B yields, and opens the angle A B C a little; during this motion round A, the short lever A E is lowered a little, and with it the long lever E F, which we will call the detent; its claw F therefore falls in the way of the tooth G, which now drops on the back part of the claw, and is inserted into a notch under the projecting heel f; the further motion of the pendulum, and consequent depression of the short lever A E, carry the end of the tooth G back again till the vibration is finished, and produce a recoil. At the moment when the tooth begins to have a recoil, the tooth D at the pallet or claw C is withdrawn and escapes; the slender spring of the lever B C, which had been bent from its quiescent state, now resumes its original situation, and throws out the lever B C, till its angle formed at B is again nearly a right angle; in the mean time the wheel is detained by the heel of the detent E F, in which situation it opposes the vibration through the medium of the two levers E F and E A, which are attached to the crutch of the pendulum. The vibration being finished, the pendulum returns towards the left, and the wheel is at liberty to advance again; the pressure of the tooth G on the claw of the detent now assists the vibration through the arc of escapement or arc of action, and causes the pallet C to approach the wheel, till the tooth following D falls on it and experiences a recoil in its turn. This recoil sets the detent F at liberty from the pressure of the tooth G, which now flies back by means of its slender spring to its rectangular situation, as it regards the small lever A E: presently this vibration terminates and the pendulum returns, while the tooth following D aids its vibration by pulling forwards the pallet C, when the process of making two successive vibrations is gone through, and the same operation is repeated. The reader will have observed in this account that the tooth and pallet, or tooth and detent, do not slide on one another, but give each other a *direct push*, or pull, the business of the small springs being to remove them from contact by one sudden leap, where rubbing is altogether avoided, which contrivance supercedes the necessity of having oil applied to the pallets, and is certainly an ingenious contrivance, as well as useful in practice. It must be observed, however, that the recoil, such as it is, takes place at the extremities of the vibration, when the momentum of the pendulum is almost exhausted, and is therefore the most unfavourable part of the vibration to occur in; notwithstanding which disadvantage the escapement has performed as well as any other that had preceded, perhaps as well as any that has followed it, as the regulator to which it was applied has seldom if ever been excelled in steadiness and accuracy of performance for fourteen years of uninterrupted succession. The imperfection arising from the recoil taking place at the extremities of the vibrations seems to have been compensated by the immense momentum of the pendulum that this escapement admitted of with a comparatively small maintaining power, while the absence of friction and of oil gave it the advantage of permanently uniform action. Of course the pendulum was of the grid-iron form, that compensated the effects of varying temperature, and allowed the escapement to have its merit appreciated. The report of the performance of Harrison's regulator with the escapement in question was, that it did not vary *one second* per day from any preceding or following day for the space of fourteen years, and that the aggregate of the variations from true mean time did not amount to half a minute.

Haley also constructed clock pallets that required no oil,

## ESCAPEMENT.

but as none of them have fallen under our notice, we pretend not to say how they differed from Harrison's.

21. *Escapement by Alex. Cumming for a clock.*—Mr. Cumming published his elements of clock and watch-making in the year 1766, in which, among other matters, he describes a construction of an escapement of his contrivance, that removes the friction and influence of oil not only during the time of rest of the pallets, but also during the motion of the swing wheel, so far as they can influence the vibrations of the pendulum; and also obviates all the irregularities that can possibly arise from the maintaining power as transmitted through the train. *Fig. 6. of Plate XXXIII.* exhibits as much of this escapement as is necessary for explaining its general action, but those readers who wish to see all the minutiae of the construction, as represented by different plates of sections, must have recourse to the book itself, as the complexity of the parts represented in various points of view demands more minute representation than our plan admits of. Our figure is a copy of plate 5 of the author, in which A B C is the escapement or swing-wheel; D E the pallets separately moveable on the axis of motion, and having each a little ball or weight H and I respectively supported by horizontal arms; each pallet with its attached weight is separately moveable from the other round its respective axis of motion, so that when one is raised by the wheel the other remains at rest; F and G are two detents firmly attached together, like the ordinary pallets of a common dead-beat or recoil escapement, and are fixed to a cylinder of brass P P, that surrounds the two axes of motion of the pallets, which are in the same straight line but separated from each other at the middle of the cylinder, where is a partition that bears the interior pivot of one axis and the exterior one of the other; the crutch of the pendulum is also fast to the cylinder; so that the two detents and crutch move together along with the cylinder, without the motion of either pallet; and each pallet can move separately without the detents and crutch. M is a load to counterpoise the detents and crutch in any position given them; and *n o* are two pins carried by the pendulum that project far enough to fall alternately in the way of the arms that carry the balls H, I, as the pendulum vibrates.

To explain the action of this escapement, let us suppose the pallets D and E, the detents G and F, the crutch L, and pins *n* and *o*, together with the balls H and I to be exactly as represented in the figure, where the lever of the detent G is hid behind the lever of the pallet E, but may be conceived to be parallel to it, the pallet D having been previously lifted from its quiescent position, where its point rested on the rim near the foot of tooth A; then if we conceive the pendulum moving from right to left with the ball I urging the pin *o* attached to an arc fixed to the pendulum, or crutch of the pendulum, the vibration is aided by the gravity alone of this ball. The arc, that bears the pins *n* and *o*, has a contrivance not seen in the figure for unlocking the detents at the moment when either of the pins bears against its ball, which contrivance it will be sufficient for our purpose to call Z. Conceive now the pin *n* brought into contact with the arm of ball D by the moving pendulum, the detent F is unlocked, and the tooth A of the wheel quits the end of pallet D; the ball H now acts by its gravity on pin *n*, and descends, at the same time aiding the returning vibration, while the pallet D, united to the arm of ball H, descends also towards the wheel; but as soon as the pendulum first began its original vibration, the pin *o* was withdrawn from the pressure of the ball I, by means of the attached pallet E falling on the tooth C of the wheel, so that all the latter part of the vibration was free; this

pressure of pallet E on the tooth C diminished the pressure of tooth A on the detent F at the instant of the unlocking, which we have mentioned; the wheel now in motion by the action of the maintaining power, (through the medium of the train,) goes on till the tooth C, acting on the pallet E, raises it outwards, together with its attached ball I, till the detent G stops the wheel's motion, when all the parts are at rest till the pendulum nearly finishes its returning vibration, and then its pin *o*, meeting with the elevated arm of ball I, presses against it and concludes the vibration; at the moment this pressure is felt the contrivance Z unlocks the detent G, and allows the tooth C to escape; in the mean time the ball I by its gravity urges the pendulum for a short time, while the tooth following A, meeting with pallet D, raises it and the ball H a second time, the tooth following C comes in the way of pallet E, and stops the further action of the ball I on the pendulum, which now vibrates, as before, free, till its pin *n* again meets with the arm of ball H, when the same process is repeated; and thus the weights H and I are alternately raised by the wheel, and then alternately act for a short time on the pendulum, at the beginning of each vibration, so that gravity alone is properly speaking the maintaining power of the pendulum, and whatever may be the maintaining power of the train, it never affects the motion of the pendulum; but only raises the balls, that afterwards act on the pendulum by their gravity alternately exerted from a state of rest. Thus, whatever may be the effects of oil, dust, friction, wear, &c. on the action of the train of wheel-work, as it has no immediate connection with the pendulum, except during the small instant of unlocking the detents, these effects are almost entirely avoided, as they regard the pendulum or regulating part of the motions. The greatest objection in theory to this construction is, that the additional gravity commences instantaneously, and also ceases instantaneously, and at a part of the vibration where the instantaneous exertion of extraneous force of any sort is the least favourable for aiding the simple gravity of the pendulum's ball, which consideration is analogous to the observation we had occasion to make on Harrison's escapement; but, like his, the escapement before us has stood the test of practical experience, notwithstanding its complexity, in his majesty's private observatory. If, however, this escapement is not better than any of the other escapements, the number of its adjustments, and variety of its parts, constitute a practical objection to its general adoption; and we believe no proof has been given of its being preferable to Harrison's, or even to the common dead-beat or isochronal escapements, except that the works of the clock that has this escapement may not require to be so often cleaned. This escapement leaving the pendulum free or detached from the wheel-work during the greatest part of each vibration, is of the third class of escapements.

22. *Escapement by Mudge for a clock.*—The clock escapement contrived by Mr. Mudge to detach the pendulum from the train, so as to allow it to have nearly a free vibration maintained by gravity alone, may be considered as a simplification of Cumming's escapement just described, from which its principal difference is, that each of his two separate pallets act also as detents; the mode of action and effect produced are very similar in both. Mr. Mudge's escapement is represented by *fig. 7.* of our last plate, in which L M is a portion of the swing wheel; G A and G B are two levers separately moveable round one common axis of motion, and have each a pallet at the lower extremities; these pallets are formed like the common recoil pallets, except that each has a claw at the lowest point, that prevents the escape of the sliding tooth when acting thereon: the pallet G A has a lever, which

## ESCAPEMENT.

which may be called its tail-piece *G O*, attached to it, and also a small metallic ball *u* surmounted on a pin over the pallet, which may be easily changed for one of a different weight; the pallet *G B* has a similar tail-piece *I O*, with a similar ball *v* over its pallet *B*; and the dark circular spot at *N* is the end of a stiff pin projecting from the pendulum, or its crutch, far enough to fall in the way of the tail-pieces alternately, as the pendulum vibrates. After having perused our account of the action of the preceding escapement, the reader will anticipate the explanation we have to offer of this mechanism. Suppose the wheel to be urged by the train in its proper direction from *I* towards *M*, and an impulse given to the pendulum, to produce a motion in it in a contrary direction; the pin *N* keeps pace with the pendulum towards *L*, while the tooth at *L* is locked in the claw of pallet *A*, (which it is supposed to have raised so as to bring the tail-piece *G O* out of its vertical direction,) and at length meets with this tail-piece, to which it gives a push, at the extremity of the vibration, sufficiently strong to drive the pallet *A* from its locked tooth *L*, when the wheel is at liberty to proceed, till the tooth near pallet *B* raises it and its surmounted ball *v* until the claw detains the further motion; in the mean time the returning vibration commences, and the ball *u* urges the pendulum, by means of its tail-piece *G O* being in contact with the pin *N*; when, however, the tail-piece has gained its vertical situation, the pallet *A* meeting with the rim of the wheel stops; the pendulum now finishes its vibration in a detached state, having gained an accession of force by the impulse from the ball *u* downwards, which has been greater than the resistance it met with in moving upwards at the instant of unlocking: the tail-piece *J O* is now in the situation of *I P*, by reason of the ball *v* being elevated by the wheel, therefore when the pin *N* of the pendulum arrives at *I P*, which is at the other extremity nearly of the returning vibration, its stroke drives the pallet *B* in its turn from the locked tooth near *M*, which now escapes; the wheel is again at liberty to proceed till the tooth behind *L* has raised the pallet *A* a second time, when it is again locked; the pendulum begins another vibration, aided by the ball *v*, till its tail-piece resumes its vertical position, and then the pendulum is again detached, after being a second time urged down a longer arc than it was moved up; and thus the vibrations are maintained by the excess of the downward push over the resistance upwards at every new vibration, which excess, derived from gravity alone, is in fact the maintaining power of the pendulum. This escapement is also of the third class, and being more simple in its construction than its predecessor and parent, perhaps we may add, is better adapted for practice. The external force derived from the gravity of the balls in aid of the pendulum's gravity is here also both applied and withdrawn suddenly, as well as at the most unfavourable parts of the vibration, as was the case with Cumming's escapement; but it possesses the same advantages of detachment from the train.

23. *Detached escapement by Peter le Roy in 1748.*—We have deviated a little from the regular order of time, in having noticed the detached clock-escapements before those that were previously applied to the balance, in order that the succession of improvements made in clock-escapements might not be interrupted by an intermixture with watch-escapements. We now go back again to the year 1748, when Peter, the eldest son of Julien le Roy, invented an escapement for a balance that vibrated a considerable portion of its total arc without any connection whatever with the escapement wheel, and which therefore may be considered as the father of the third class of escapements, and the origin of the subsequent more recent improvements in the escape-

ment of chronometers. *Fig. 8 of Plate XXXIII.* will afford us the means of explaining this escapement, a model of which was presented to the Academy of Sciences at Paris in the year 1748, previously to which year, no detached escapement had been made public, though Du Tertre is said to have invented one, and even to have made it at the time; but as the invention, or at least the construction, was kept a secret, it did not derogate from the merit of Peter le Roy's contrivance, which must be considered as original. *G H* is the escapement wheel of the contrary kind, actuated by a pinion on its arbor, receiving the force of the maintaining power; its profile is seen contiguous to it, at *g b*; *T V* is the balance, the verge of which has a spiral spring attached to it at the interior end in the usual way; a curved pallet *A E* is fast to the verge under the balance, and the semi-circular piece *C I* is affixed to the same above the balance, but under the spiral spring; the end *C* of this piece is rounded, and so situated, that a line drawn from it to the centre of the balance would form with the curve *A E* an angle of about  $80^{\circ}$ . An angular lever *Q P X*, turning on pivots under a little cock on the plate at *C*, is so proportioned, that the branch *P Q* will reach the pallet, while the other branch *P X* with a concave end will reach to a tooth *G* in the balance wheel, when not resting on a pin *K*, to which in its quiescent state it is kept by the spring *R M*, made fast to the plate on the other side at *R*. Suppose now, the regulating spring moved from its state of natural rest, and the balance to move with it through a certain arc of vibration, more or less, till the rounded end *C* of the semi-circular piece falls on the branch *P Q* of the angular lever near *Q*, and pushes it from its situation, at the same time bringing the concave end of branch *P X* into the way of a tooth *G* of the wheel; when the acting tooth, which we will call *D*, escapes the pallet *A E*; the wheel is then at liberty till its tooth *G* falls on the concave end of the branch *P X*, which may be called the detent, because it now *detains* the wheel from moving further under existing circumstances. The balance is now perfectly free from all contact of the acting part of the branch *P Q*, and continues its vibration, after having received a push from tooth *D* on its pallet: presently its velocity is destroyed by the tension of the regulating spring, the re-action of which now makes it return with an accelerated motion, when the pallet comes into contact with the escapement wheel at the tooth following *D*, which now experiences a recoil for about half of a space in the wheel: the branch *P X*, or detent, is relieved by this partial recoil, and obeys its spring *R M*, which takes it back again to its state of rest at the pin *K*; when the wheel, having stopped the balance, sends it off again with a new impulse, by striking the pallet in a contrary direction, when the same operation of the angular lever is repeated, and the vibrations are maintained as in other escapements. It must be remarked of this escapement, that it does not allow the balance to be detached for an entire vibration, but opposes the balance back from the point where it gave its forward push, thereby producing a certain recoil, which, so far as this is a leading consideration, would entitle us to rank the escapement among those of the first class, but inasmuch as the balance vibrates in a detached or free state in the remaining portion of its vibration, we may place this escapement with propriety at the head, in point of time of the third class.

24. *Peter le Roy's second or improved detached escapement.*—Some time after Peter le Roy had completed his first detached escapement, and had considered its principal defects, he set about contriving another, less liable to objections, in which he succeeded in a very considerable degree: when in

## ESCAPEMENT.

the year 1766 he presented a time-piece to the Academy of Sciences, which was afterwards tried at sea by the French government, with his improved escapement, which we shall now describe. *Figs. 1, 2, and 3, of Plate XXXIV.* exhibit sufficient of Peter le Roy's improved escapement to enable our readers to form a complete idea of its construction; the leading feature of which is to give the balance one temporary push that shall maintain its motion for two successive vibrations, one forwards and the other back, and that this push may be given at a moment of the balance's vibration that is most favourable for avoiding a derangement of the law of the spring's forces. *Fig. 1.* is a view of the balance-wheel, which has six radial levers for teeth, but no rim, that it may be as light as possible, the ends of which levers are bent downwards, that is, in an opposite direction to those on the horizontal wheel with Graham's cylinder escapement; the connection of this horizontal balance-wheel with the train is by means of the pinion on the opposite end of its arbor; *fig. 2.* is the arbor of the detents, on which there are three levers, one double one for locking, and two single ones for unlocking, all clearly shewn in the figure; *fig. 3.* shews the wheel, detents, unlocking levers, and balance in their relative situations, and in one of the acting positions: *A* is a portion of the balance, on the plane of which is screwed a pallet *p*, so as to fall in the way of one of the levers of the balance-wheel. The same letters denote the same parts in *fig. 3.* as in *figs. 1 and 2,* which therefore explain themselves. The action may be explained thus: suppose one of the levers of the balance-wheel to be detained by the claw of the detent *D*, while the balance put in motion is vibrating in the direction from *i* to *A*; when the force of the balance spring, not seen, overcomes the momentum of the balance, it returns by means of the spring's force, which is now at its greatest tension, or distance from the point of quiescence; the direction of the balance, we have said, is now from *A* towards *i*; in this return a pin at *i*, situated in the superior plane of the balance, strikes the end of the lever *H F* of the detent arbor, unlocks by this stroke the detent *D* from the claw of the wheel's radial bar or tooth, and at the same instant directs the other end *H e* of the double detent into the way of a succeeding radial bar of the wheel *K r*, which now rests on this end of the detent; this part of the action is called by the inventor the *preparation*, the vibration goes on to finish, and the spring brings the balance back; at a certain part of this vibration the balance receives its stroke from the radial bar *K*, which impels the pallet *p*, screwed on the balance itself, in this manner; a pin, situated like the former pin at *i*, but placed on the inferior plane of the balance, out of sight, and a little farther from the balance's centre than the former pin, strikes the end of the short lever *H e*, and unlocks the radial bar of the wheel, that has been resting against the opposite end of the detent *D*, and that now runs on to *D*, which is in the way to catch it; during this short period the wheel is free, the pallet *p* of the balance being at that instant in the situation *F*, the point *K* of the radial bar *K r* of the wheel pursues the pallet and makes its stroke on it, about the time when the balance spring, as we suppose, is at its quiescent point, and therefore when the balance is moving with its most accelerated velocity; the stroke is of short duration on that account, as well as on account of the short distance the wheel has to run before it is again detained by the detent *D*: the backward vibration is made as before, and the same process is repeated of two lockings and unlockings at each stroke of the wheel on the balance. The stroke, however, which the balance receives, has more force than both the strokes that its pins give in the acts of unlocking, and

therefore the difference of these contrary strokes constitutes the real maintaining power of the balance, which was of the thermometrical kind, with alcohol and quicksilver, as described under our article *COMPENSATION-BALANCE*. The step made towards perfection, when this escapement was devised, was very long, and the principal objection to it in practice is, that it has too many pivots that require oil, as well other parts that come successively in contact during the action, which therefore are not sufficiently free from friction and consequent wear. It may be necessary to add, that to prevent the detent's being displaced by any jerk, a long tail-piece behind it is contiguous to a circular appendage of the balance, seen from *i* to *F*, against which it falls; but only when any derangement of the detent accidentally takes place, and thus reinstates it. The stroke is given to the balance not only when its velocity is greatest and least liable to be deranged, but the pallet that receives it, being removed from the centre of the balance, requires but a comparatively small impulse in this situation; besides, the spring, which the inventor considered as not desirable, for holding the angular lever to its place of locking, is here entirely dispensed with. This was considered as an improvement at the time, but subsequent experience has proved the utility of spring detents, which are now in universal use in the best English chronometers.

25. *Detached escapement by F. Berthoud.*—Ferdinand Berthoud, one of the members of the National Institute of France, and the author of various works on horology, has contrived different escapements for clocks and watches at different times, and has written more on the subject than any other author, but it will not come within our plan to detail here all the alterations that have presented themselves to him; we shall satisfy ourselves with describing a few of those which he has himself selected as most worthy of public notice in his last publication; "Histoire de la Mesure du Temps." Others may be seen in his "Traité des Horloges Marines;" or in the "Supplément" to that work. The first that we mean to describe is contained in *fig. 4.* of *Plate XXXIV.*, which is a perspective view of all the parts necessary to be seen: *A* represents the verge of the balance, to which is affixed by two screws the circle of escapement *B* as a pallet; *C* is the escapement wheel, *a b c* the detent, which has at *b* a claw to catch a tooth of the wheel, when it suspends its motion, during the period of the balance's free vibration; the portion *a b* of the detent is a flexible spring, that yields first at the point *a*; this, therefore, is the *spring of the detent*; the other part *b c* properly forms the detent, which has a claw rounded at the end *c*; another slender spring *b e* lies cross-wise near the said end, and is held fast to the circle *B* by a screw and fixing-piece *f*; this second spring carries a pin *d* near its extreme end, which acting on the end of the detent, disengages the locked tooth of the wheel, when the balance vibrates in a direction from *B* towards *A*; at that instant the succeeding tooth of the wheel acts on the notch or pallet part of the circular piece *B* at *b*, and transmits an accession of force to the balance, which now vibrates in free space; at the balance's return, the pin *d* of the small spring *d e*, borne by the balance's circular piece *B*, applies itself to the end of the detent, so as to slide past it without disturbing its position with regard to the claw, against which the next tooth is now resting; when the balance has finished this second vibration it returns, the pin *d* again pushes aside the detent, and unlocks the wheel, which now gives another push at *b*, and the same operation is resumed that we have been describing. Thus two vibrations are performed at once unlocking, and at one stroke of the wheel on the notch of the circular pallet piece. The small spring *b e* may be

## ESCAPEMENT.

be called the lifting spring, in opposition to the detent spring, or spring detent; and to give a clear idea how it detaches the claw of the detent in passing forwards, but not in passing back again, it may be necessary to observe, that this lifting-spring has a pin in the circular piece B, against which it rests, to prevent its laying too much hold on the back sloping part of the detent's extremity; but it is at liberty to yield in the contrary direction towards the verge of the balance; and as the spring is very slender, and has its yielding point or centre of motion at the remote end *e*, it gives way to the detent in the direction that pushes the detent against the tooth of the wheel, which becomes a prop to steady it; but when the impulse is in a contrary direction, the detent, having no such prop, and its end being at that side suited to receive the blow of the pin without its sliding, itself yields and withdraws its claw from the wheel, which is then unlocked. The spring of the detent is also confined from rebounding too far by a pin *g* fixed in the plate. Here we have an instance of a retrograde step in the improvement of escapements, the spring which Peter le Roy laboured to reject in his second construction is here resumed with an additional spring, and the adoption of the *spring-detent* has become general in the subsequent constructions. Berthoud began his detached escapements in the year 1754.

26. *Another modification of a detached escapement by Berthoud.*—The escapement which Berthoud employed in some of his watches, particularly N° 60, was considered by him to be more sure in its action than the preceding one, as well as more easy of construction; *fig. 5.* of the same plate represents the plan of one of these escapements, where L is the escapement wheel; *m* the circle of escapement carried on the verge of the balance; *p or r* the detent, the claw of which at *r* suspends the motion of the wheel; the verge carries above the circle *m* a small tube made fast by friction, and to this tube is made fast a projecting forked claw, in which a pin is adjusted to act on the detent and raise it. The pin, which we will call *s*, in turning in one direction, acts on the part *p* of the detent, and withdraws the claw *r* from the wheel; this is now at liberty to impel the circle *m* by its notch and with it the balance; the slender spring *u* brings back the claw of the detent, and the vibration goes on; at its return the pin meets with the end of the detent-spring fixed on an arm at *t*, this spring yields to the retrograde motion of the balance. The balance at its return makes its pin (of the fork) urge the spring *p* against a pin *s* in the arm *n* of the detent; this arm turning on its centre of motion, withdraws the claw of the detent from the wheel, which now acts again on the notch of the circle *m*, as before. The pin *q* serves as a stop to the detent, and the arm *k* of precaution is to lock the wheel when the balance is dismounted.

27. *Another escapement without a spring by Berthoud.*—*Fig. 6.* of the last plate is a view of an escapement by Berthoud, in which he has dispensed with springs altogether. The action of the wheel A is transmitted to the balance, as before, by the notch of the circular piece B on the verge; the present position of the parts is for the moment when the detent allows the wheel to begin its action on the notch of B. The detent C has two arms, with each a claw *a* and *b*, the faces of which are circular; the claw *a* serves to suspend the action of the wheel after its stroke is made; but the claw *b* receives the tooth of the wheel when the balance in its return makes the tooth at *a* to escape. These effects are produced by two levers C *d*, C *e*, forming the fork that moves the detent C: this fork is fixed on the centre C of the detent, and its levers lie one above the other. The lever C *d*, which is contiguous to the detent, corresponds to

the small semi-circular piece *d e*, placed on the circle of escapement B; this semi-circle is notched by lines, one of which tends to the centre; this side of the notch unlocks the wheel by its action on the arm C *d* whenever the balance retrogrades from the first vibration of the pair; during this effect the wheel advances but a short way, just sufficient to unlock the claw *a*, and to suffer the balance to proceed in its retrogradation. The balance, having finished in a detached state this second vibration, returns, when the semi-circle *f g*, placed over the other semi-circle, and notched in like manner, presents its acting side to the upper arm *f C* of the fork, and unlocks the tooth at claw *b*; at this moment another tooth, catching the notch at *e* of the circular piece B, gives it another impulse, and consequently puts the balance in a state of renewed force, and the process already described is renewed, while the semi-circular pieces *d e* and *f g* on the verge alternately serve to keep the arms C *d* and C *e* of the fork in a firm position to ensure the desired effects of the escapement. It is easy to perceive that there must be much friction in this escapement, and that the semi-circular pieces on the verge of the balance, if not somehow counterpoised, must affect the rate of going in different positions of the time-piece.

28. *Detached escapement with a detent and spring by Berthoud.*—*Fig. 7.* of the same plate is the plan of another of Berthoud's escapements with a detent and spring, and that which we understand has been most copied by others. It was used in the author's marine time-piece N° 9. A is the circle of escapement; C the wheel; *a b d* the detent with three arms; the arm *a* suspends the motion of the wheel while the balance oscillates in a free state; the spring *d* serves to bring the detent *a* back again as soon as the pallet *c* has ceased to act on the arm *b*; at that moment one of the teeth of the wheel impels the circle by acting on the roller *h*, and communicates its force to the balance; this having finished its oscillation returns, and in the return the pallet *c* meets with the end *b* of the detent, which turns the pallet back towards B, the centre of the circle, till it has passed without unlocking the wheel; its spring *b* brings the pallet back again to its original state of rest on the pin at *e*, the oscillation ceases, and in the return of the balance the pallet *c* again meets with the arm *b* of the detent, which it turns aside, the tooth being no prop to it in this direction; the unlocking therefore takes place; the wheel's motion is resumed, and a new impulse is given to the moving balance. Here the detents are arms or levers acted on by a separate spring, as is also the pallet, consequently there still remain pivots that require oil, though we are disposed to consider this as the best of Berthoud's watch escapements; perhaps equal to any of the English constructions.

29. *Isochronal escapement of a watch by F. Berthoud.*—Among the other contrivances of Berthoud is an escapement for a watch with isochronal pallets, similar to those applied to a pendulum which we have described above, but the mode of applying them is different. In *fig. 8.* of our last plate, A is the escapement wheel; B the anchor with the isochronal pallets producing a small recoil, and formed in the manner before described, (*see fig. 1.* of Plate XXXIII.) C D the balance; *a* a pinion on the verge above the wheel, that is actuated by a sectoral toothed piece *b*, attached to the anchor of the pallets, and moving with it round the common centre of motion of it and the pallets at E; the intention of this construction is to produce a long oscillation of the balance compared to the motion of the wheel and toothed sectoral piece, and to render all the oscillations, however long or short, of equal duration, the arcs of action being large in proportion to the whole oscillations. This construction may

## ESCAPEMENT.

may have given rise to that which is now known by the name of the Liverpool escapement, which so greatly resembles it, that they may be considered as the same thing. We obtained a watch by Litherland of Liverpool, with a view of giving a separate description and drawing, but we found that the only difference is, that the pallets are placed a little on one side of the wheel, instead of the three pivots being in one straight line, and that the centre of the pallet's motion is between the verge and pallets requiring a counterpoise behind: a further description is therefore unnecessary.

30. *Modern escapements of English chronometers.*—If we had not already anticipated our descriptions of the modern escapements for chronometers, as they are now made in England, we should have given them a place here; but as we have been very minute in our account of the escapements of Messrs. Mudge, Arnold, the Brockbanks, and Earnshaw, under our article CHRONOMETER, and have given drawings of them in our *Plates XIII. XIV. and XV.*, it would be superfluous to enter into a second detail of the same here, and therefore we pass over them by a simple reference to the article already named.

It may not be improper to mention here, that Mr. John Watkin, of West Smithfield, has proposed an alteration in the situation of the pallets in the modern spring-detent escapement, for which he received thirty guineas as a premium from the Adelphi Society, in the year 1804. His alteration consists in bringing the pallets into a situation between the centre and circumference of the wheel, and making the wheel a contrate one with the teeth upwards. (See the *Transactions of the Society*, vol. xxiii. p. 375.)

31. *Mudge's forked escapement.*—Mr. Mudge contrived another detached escapement besides the one we have referred to as already described, which we shall now notice, though he did not seem to place so much value on it as Emery, Margetts, and others have done after him; we shall not be able to make the reader comprehend the construction without two figures: *fig. 1.* of *Plate XXXV.* is the plan of this escapement, and *fig. 2.* a profile or side view of the frame that contains the mechanism: A is the escapement wheel, B the anchor of the pallets, which are of Graham's dead-beat kind adapted to a watch, and which give the necessary force to the balance for maintaining its motion; *a* is the centre of motion of the anchor, nearer to the wheel than to the balance; *b* is the forked part of the anchor, the two prongs of which appear in *fig. 1.* to be close together in the same plane, but *fig. 2.* shews that they are one above the other. The pallets are on the verge of the balance, and are of the cylindrical sort, one above the other, so as to fall in the way of the two prongs alternately, pallet 1 is urged by *b*, and pallet 2 by the other prong in its turn; the time of action of the prongs on the two pallets is very short, and the blows are made alternately one in each vibration; the remainder of the vibration is perfectly free, the wheel being in the intervals resting on the circular portions or pads of the anchor's pallets, which may in this case be considered as detents and pallets alternately. A time-piece by Emery with this escapement performed with wonderful accuracy, though the detachment continues only for a portion of one vibration before the balance has its force renewed, which consequently might be supposed to have its motion more disturbed than if the impulse had been given at each alternate vibration. The queen's watch by Mudge with this escapement had a slight recoil, which kept one of the prongs pressing gently against the cylinder of the verge to steady the fork. The performance was excellent.

32. *Margetts' modification of Mudge's forked escapement.*—The late ingenious Margetts adopted Mr. Mudge's escape-

ment, which we have just described, for his chronometers that indicated both solar and sidereal time, but made some alterations with the fork. *Fig. 3.* of the same plate shews the plan and profile of Margetts' modification, where A is the wheel; *a b* the anchor moveable at *a*; *b* the fork where the prongs are in the same plane; *c* a piece of steel carrying a pin *e* under its extreme end that strikes the prongs of the fork *b* alternately, one at each oscillation of the balance *g*, which strokes unlock the wheel; *b* and *i* are two banking screws, the points of which act as stops to the anchor at opposite sides of the centre of motion, and keep the fork in its place to be caught by the pin *e*, one or other of them at each vibration; *d* is a circular piece of metal, under the pallet piece *c*, that has a notch in it bounded by straight lines going towards its centre; and *f* is a pin carried under the anchor, as seen in the figure, the end of which gives the circular piece *d* a push, by acting on its notched side at each unlocking of the wheel, thereby aiding the vibration: the pin *f* is always at the notch when the pin *e* is in the fork, therefore the notch in *d* and the pin in *e* are always placed in the same vertical line over one another, and as they move together on the verge will always remain so, while the pin *f* and fork *b* are also together on the anchor. The writer of the present article has a chronometer by Margetts with this escapement, which acts very well when stationary, but when carried in the pocket the pin is apt to catch the outside of the prong, when any jerk has sent the anchor back during the balance's excursion.

33. *Modification of Mudge's forked escapement by R. Robin of Paris.*—R. Robin, a watch-maker of Paris, published a memoir in 1794, containing an account of a free escapement, which he considered as new, but which we consider as another modification of Mr. Mudge's forked escapement, though we allow that in theory it appears to be an improvement. *Fig. 4.* of the same plate is a plan of this escapement, in which the wheel restores the exhausted force of the balance once only in two vibrations, which circumstance constitutes the improvement; to effect this, pallets G *a*, and G *b*, acting as detents; are made of unequal length from G, the centre of their motion, and the fork, which is seen separately at *e*, as well as the tooth or pallet *d* and lever *f*, are concealed under B, the circular piece carried by the balance; the fork *e* is fast to the end of one of the pallets *a*, instead of forming an anchor with the pallets, but this shape makes no difference in the action; the lever *f* is also fast to the same underneath the fork; but the tooth *d*, which acts with the fork, is fast to the verge under B, as we have already said. We have given three positions of the circular part B and pallets, to shew more clearly the nature of the action, as some of the acting parts are concealed. One of the claws *a* of the pallets being removed, the wheel A escapes, and acts on the notch of the piece B, thereby aiding the balance; the claw *b* receives another tooth and holds it as a detent, and the balance finishes its oscillation; at its return it unlocks the tooth at *b*, which is the longer pallet, and the wheel runs on a very short way till a leading tooth falls on the pallet *a*, and the balance vibrates without a new push; at its return the tooth at *a* is unlocked, and its escaping tooth gives the notch of B another push, which serves for other two vibrations; but if the two ends of the pallets G *b*, and G *a*, had been of equal lengths, the escapement would have acted in the usual way, and would have given its push at each oscillation. The manner in which this effect is produced, however, does not yet appear evident; the lever *f*, which is fast to the end *a* of the pallet or detent G *a*, rests in a groove made in a circular collet on the verge, and holds the fork *e* from going on one side, like as the banking

## ESCAPEMENT.

screws do in Margetts' escapement, then the tooth *d*, fast to the balance, strikes the two prongs of the forks alternately, one at each vibration, which strokes make two unlockings during the time that one push is made to the balance by a tooth; because the said tooth previously made two steps forward, one long and one short, before it escaped to make its push. We have not been informed how this modification performed, but we see no reason to doubt its competency, while we see much reason to admire the ingenuity of the application of two detents of unequal length, formed like the pallets of the anchor escapement, which detents we have named pallets on that account.

34. *Prior's modification of Mudge's forked escapement.*—In the year 1798 Mr. John Prior received 30 guineas as a premium from the Society for the Encouragement of Arts at the Adelphi, for his invention of what he considered a new detached escapement; but its fork differs from Mudge's principally in its having a roller for a pallet borne by an arbor carried by the balance itself; the wheel of escapement, together with its acting pallets, were similar to Le Paute's improvement on Amant's wheel, and therefore had nothing original in it. The reader who wishes to see the account and drawings of this escapement, composed as it is of Mudge's and Le Paute's contrivances, which notwithstanding the author might not have seen or known, may find it in the 16th vol. of the Transactions of the Society just named, and also in the 2d vol. of Nicholson's Journal, 4to. ed. p. 363 and 364, where the editor has remarked that Mr. Crothwaite of Dublin had made a pendulum clock with similar pallets in 1788, which was described in the Memoirs of the Irish Acad. vol. ii.

Prior junior has very recently been rewarded by the same society for another escapement contrived by him for a clock, but the account of it is not yet published in their Transactions, and therefore cannot with propriety be given here.

35. *Duplex escapement.*—We are not informed who was the original contriver of the escapement known by the name of Duplex escapement, a name probably taken from the circumstance of its having a wheel with two sets of teeth necessary for the escaping; neither are we aware of its date; but the esteem in which it is held by those who have tried it, entitle it to a place in our collection. *Fig. 5. of Plate XXXV.* exhibits on a large scale enough of the acting parts to enable us to convey an idea of its action. A B is a part of the escapement wheel, having teeth *a, b, c,* &c. at the periphery, intended for detaining the wheel while it oscillates beyond the angle of action. An agate cylinder *def*, placed on the verge of the balance, acts with these teeth to produce the desired effect. This cylindrical agate has a notch *d*, which passes by the tooth at D, that is supposed to rest on the cylindrical surface, when the motion is in the direction *def*; but when the motion of the cylinder is in the contrary direction *fed*, the tooth at D falls into the notch and accompanies it, pressing on one of its sides till the notch comes into the situation *d*: the tooth, then at the situation of *b*, escapes from the notch, and a succeeding tooth falls on the convex surface of the cylinder at D. The other set of teeth are erect on the plane of the wheel's rim, and are strong and squared at the sides; they stand a little short of the middle of the spaces between the pointed teeth on the edge of the wheel, but consist of the same number; they are to be seen at *b, i,* &c. denoted by darkened parallelograms: above the small cylinder we have named as being made of agate, is a larger one E F G without a notch, and placed high enough on the verge to go over the edge of the wheel's rim; this bears a pallet of ruby or sapphire G, long enough to fall in the way of the square vertical teeth,

when they happen to be near the line joining the centres of motion of the balance and wheel, but short enough to avoid touching the teeth when not near that line. The larger cylinder is so placed with respect to the small one, that when the tooth *b* has just escaped from the notch, the pallet G has just passed the square tooth *b*, which was at A, while D rested on the small cylinder, but is moved from A to *b*, while D moves to *b*. The wheel is now free, and the tooth *b* exerts its force, derived from the main-spring, in the most direct way on the pallet G, and urges it forward till another tooth on the edge falls on the convex part of the small cylinder *def*, and the same action that has been described is resumed. The angle of action in this escapement depends partly on the length of the pallet G, and partly on the diameter of the small agate cylinder, and advance of tooth D into the notch; for when a horizontal tooth on the edge falls on the said small cylinder, the motion of the wheel is arrested, and the vertical square tooth ceases to impel the pallet G so far as it otherwise would have done. This escapement requires very little oil on the small agate cylinder, and none at all on the pallet G, which receives a direct push without friction, and its excellence is considered as at least equal to that of Graham's horizontal or cylindrical escapement.

36. *Free escapement under the pendulum.*—The clock escapements which we have before described suppose a connection with the upper end of the pendulum, which is the most common connection, but there are escapements that give their impulse at the inferior end, one of which is represented by *fig. 8. of Plate XXXV.* which we shall now describe, though we know not who was its original contriver. The part A B D C is made fast to the rod of the pendulum, and vibrates therewith; at B is a joint on which the lever B C is moveable; so that when the end C meets with any resistance the lever mounts upwards at this end, but cannot fall below a horizontal line; it terminates in a claw with both an interior and exterior slope or inclined plane; D is a pallet of agate or other polished stone, with a flat face next the end C of the lever, and made fast into the vertical part A D; F G H I is a two-armed detent, moveable round H as a centre, but kept in its present position against the stop or pin K, by means of the weight G, when not otherwise acted on. In the present position the arm H I, which forms the detent, detains the tooth I of a vertical wheel of escapement, while the pendulum is supposed to be vibrating clear of all the teeth. Let us suppose the end C of the horizontal lever, moving with the pendulum, to be approaching the end F of the second arm of the detent; presently it gives the end F a blow, the lever C flies up, slides over the inclined face of F, and returns into its horizontal position; when the vibration terminates, the pendulum returns by virtue of its gravity, and the interior face of claw C catches the exterior one of the arm F, and gives it a pull sufficient to draw the end of H I from the tooth I; the wheel is then at liberty to run on till the tooth E, moving faster than the pendulum, overtakes the pallet D, and gives it a direct push forwards; this push aids the claw C to get over the claw of F, and the weight G replaces the arm H I to catch the following tooth M, which prevents the further impulse of the wheel on the pallet D, and suffers the pendulum to finish its vibration in free space; at the return of the pendulum the same operation is repeated, and the pendulum continues to receive one push at every two vibrations, and that when the pendulum is in its vertical position, or moving with its greatest velocity, which we have said is the most favourable point of the arc. The arc of action, before the pallet is quitted, depends greatly on the

## E S C A P E M E N T.

the radius of the wheel compared to the length of the pendulum, when the number of teeth is limited. The pendulum, however, ought to be of the compensating kind, otherwise an increase in the length of the rod will derange the action of the claw C, with the claw F, as well as of the tooth on the pallet D, in all the extremes of atmospheric temperature. The maintaining power of the train that actuates the wheel E M may be either a spring or weight, as the mechanist may think proper. Berthoud has proposed this construction of a free escapement for a half-second's pendulum in his "Histoire de la Mesure du Temps," tome i. p. 214; but he does not clearly say that it was of his own contrivance; on examining his drawings, since our observations were written on this escapement, we find that this author proposed a compensation pendulum to be used with it; and he proposes such a combination of parts as a proper model for an astronomical clock to vibrate half-seconds. Mr. Nicholson, who has also described the same escapement as one he has noticed in England, does not venture to ascribe its invention to any particular artist.

37. *Detached escapement of a clock by Berthoud.*—Among the numerous contrivances of F. Berthoud in clock-work, we frequently find this author applying the same contrivance to answer different purposes; for instance, when he had hit upon an isochronal escapement for a clock, he adapted it soon after, as we have seen, to a watch; and in the instance before us, he has converted a free or detached escapement of a watch into a clock escapement, which we shall here describe, not knowing the exact date of the application. *Fig. 1.* of *Plate XXXVI.* is a representation of an escapement of the third class adapted to a half second's pendulum, as described by Berthoud himself. F is the escapement wheel, and *a, b,* the detents of escapement, (formed like the pallets of the dead-beat escapement of Graham,) the action of the wheel F is transmitted to the pendulum by means of the notch made in the circular portion of the escapement piece A B, thus; the detent has two claws, *a* and *b,* formed by portions of a circle, at the holding parts. The claw *a* serves to suspend the action of the wheel, when it has communicated its motion to the notch of the escapement piece, which this does again to the pendulum, by means of the lever C, which it carries, and of the roller D, corresponding to the pendulum. The claw *b* serves to receive, and to detain the wheel, when the pendulum returns. These effects are produced by two levers *d, c, e, c,* fixed on the centre *c* of the detent; but one of them more distant from the plane than the other. These two levers form a fork that corresponds to the circle of escapement *b g.* The lever *d, c,* which is nearest to the detent, answers to one portion of the circle *g,* carried by the circle of the escapement D. This part *g* presents a straight line to the fork *d,* which being acted on, detaches the claw *a* of the detent, and, consequently, sets the wheel at liberty. The notch *f* presents itself, and the tooth of the wheel acts on the notch, and restores to the pendulum the force that it had lost. The wheel having finished its action on the notch *f,* a tooth presents itself to the claw *b,* and the pendulum finishes its vibration in a free manner, at its return, the portion of the circle *g,* which is most elevated, meets with the arm *e* of the fork, and disengages the claw *d;* the tooth that was here detained now escapes, and runs on a short space before another tooth drops on the claw *a,* and the process is repeated. We have not seen this escapement in England.

38. *Escapement by Mr. Nicholson.*—Some time in the year 1734, Mr. Nicholson says (Phil. Jour. vol. ii. 4to. p. 59.) that he contrived a clock escapement to go without oil, and which is of the dead-beat kind; it was constructed in the

year 1798, and when the account was written had been going freely for a year or more. His account is this, *fig. 2.* of *Plate XXXVI.* "is a sketch, in which G H represents a steel wheel; D and E are pallets of agate, with flat polished faces. The pallet D is fixed to the lever D C, which is confined to its present situation by the loaded branch or arm C B resting on the stop *k.* The lever E C is also kept in its situation by the loaded arm C A resting upon *l.* A pin N proceeds from the pendulum rod to its situation between the levers. The centre of motion of the pendulum is in the continuation of the axis of the pallets. Suppose the vibrations to be begun; the pin N in its progress will lift the pallet D towards L, while part of the weight B will be supported by the tooth of the wheel which will follow, and at last escape and suffer the opposite tooth F to fall on the pallet E. But in its return, or descent, the pendulum will be acted on by the whole weight B, and, consequently, its vibration will be kept up. When the pin N raises the pallet E, a similar effect will take place on the side of the perpendicular towards M, and thus the process will go on as long as the wheel G H retains any force." In this escapement, the two weights are not raised entirely by the action of the wheel, but are chiefly lifted by the pendulum itself; therefore though the vibration is made during the repose of the wheel, in a state detached from the train, yet the pendulum is not detached from the weights, and, consequently, the compound law of forces by which the pendulum is maintained consists of the action of the pendulum's gravity, of the action of the ball's gravity, which acts in concert with the other, and of a short action of the wheel on the agate pallet; this compound action differs from Mudge's and Cumming's in this respect, that their weights are raised by the wheel entirely without opposing the pendulum, otherwise than by the short stroke made at unlocking.

39. *Crank escapement by Simon Goodrich.*—In the year 1799 the Adelphi Society rewarded Mr. Goodrich for his contrivance of a crank escapement, which is exhibited in *figs. 3.* and *4.* of *Plate XXXVI.* of which *fig. 3.* is a front view, and *fig. 4.* a side view of the same, where the same letters of reference apply to both. A A A A is the back plate of a clock frame; B the crank fixed to the end of C the arbor of the last pinion of the train; D, D, are two small wire chains, composed of two links only attached to the crank B, by means of two coilets, with great liberty of play. These chains are fastened to E, E, two small springs screwed to F F F, a bar that goes across, and is fastened in the middle to G G, the crutch of the pendulum. I, I, are two screws going through the bar F; the ends of which being made to act against the springs E, E, serve to adjust them to a proper distance and degree of strength, and by that means easily to put the pendulum into proper beat. In *fig. 3.* the pendulum is partly represented by dotted lines, in order to shew the crank, &c. The advantages attributed to this construction are, simplicity of construction and consequent cheapness; total silence during the escape; uniformity of action on the pendulum; durability and certainty of continuance; and the power of acting without oil. These properties may recommend the escapement before us, but as its influence on the pendulum is constant, it is but ill calculated to counteract any irregularities in the maintaining power as transmitted and varied by the train under different circumstances of wear, dirt, and friction. The originality of the contrivance is that of a rotatory motion converted into a vibratory one, which Soumille had done very nearly in the same way in the year 1746. (See *Machines et Inventions approuvées par l'Académie Royal des Sciences; tome xiii. p. 325.*) As there is no escapement wheel, a

further explanation is unnecessary to every one who has seen a treadle in action; but it may be necessary to remark that an additional wheel and pinion must be requisite in the train where the last pinion revolves more frequently than in other escapements.

40. *Escapement without a verge on the pallets by Ed. Maffey*.—Mr. Maffey's escapement without a verge was one of two escapements which together gained him twenty guineas from the Adelphi Society in 1803; the other, being of the 4th class, will be described in another place. *Fig. 5. of Plate XXXVI.* is a plan of this escapement, which is of a novel construction, borrowed probably from the spring detent escapement of the modern chronometers, and adapted to a clock, where the pendulum is free, during a large portion of its vibration. The pendulum rod is seen at *a*, suspended by a piece of watch spring in the usual way, but without a crutch and verge; *b* is the swing wheel with its teeth shaped like the dead-beat kind, except that they are rounded at the end; this wheel is not within the frame as usual, but on the outside of the back plate; *c* and *d* are the arms of the pallets *f* and *g* respectively; these arms are attached to the frame, and are adjustable for the included angle by the screws *b* and *i*, which press against the upper ends of the arms, that open like a pair of tongs, and are kept open by a slender spring *e* forced into notches at the ends. A cross bar *k*, carried by the pendulum, gives alternate strokes to the two pins fixed in the pallets *f* and *g*, at the time of unlocking. In the figure the pendulum is supposed to be in motion with the pin of pallet *g* resting against the cross bar *k*, which bar it impels on the returning vibration, and aids the pendulum, while the inclined plane of pallet *f* is raised by the wheel to give its stroke, when unlocked, in a contrary direction. Thus the pallets are raised partly by the wheel and partly by the pendulum, as is the case with Mr. Nicholson's pallets; for the spring in this case performs the same office that the weight does in that; but in this escapement the inclined planes must require oil, which is not necessary in the other, where the wheel acts by a direct push without any sliding motion. The inventor tells us, that a more than usually large maintaining power is necessary when this escapement is adopted, which indeed must be the case with all detached escapements, where the duration of the impulse is short.

The reader may have observed that we have not yet noticed in this article the fourth class of escapements which act by the aid of *remontoirs*; this omission has been intentional, not only for the purpose of avoiding the further enlargement of the article, but that we may give the history of the invention of the *remontoir*, and of its modifications by the different ingenious men, who have preferred its use to that of a detached escapement without such additional aid. We have already had occasion to speak of Harrison's and Mudge's auxiliary springs, or *remontoirs*, under our article CHRONOMETER, and it will suffice, for our present purpose, to name here that Huygens, Leibnitz, Gaudron, Haley, Breguet, De Lafons, Maffey, Mendam, Antis, and others have taken a part in bringing the *remontoir* into notice, as we shall have occasion to relate more particularly under the article REMONTOIR.

ESCARAY, in *Geography*, a town of Spain, in Old Castile; 5 miles S. of Calzada.

ESCARIGO, a town of Portugal, in the province of Beira; 12 miles N.W. of Penna Macor.

ESCARPE, or SCARP, in *Military Affairs*, relates to the exterior slope of each defence, while on the other hand the interior slope of every excavation beyond or facing the escarpe is designated the counter-scarp. It may be necessary to remark, that, in strictness, the term is not applica-

ble, except where some talus or slope is given to the exterior, though it is in very general and indiscriminate use. Originally, when the sides of hills, &c. were to be defended, it was found necessary to remove all such masses as might afford cover to an approaching enemy, or enable them to ascend to the assault; each rugged exuberance being in such cases adequate to the steps of a ladder, and offering a footing to the assailants.

To avoid this facility of attack, it became customary to chip away the prominent parts, and to render the surface inaccessible; this was effected by *escarping* it, (from the French verb *escarper*, to cut steep or sloping,) in such manner as to render it impossible for any one to ascend without the aid of ladders, &c.; giving at the same time a direct line of fire to the defenders, and enabling them to roll down stones, &c. with prodigious effect, upon such as should have the temerity to assault.

Latterly, however, the term has been applied to the exterior face of the works, whether the wall, or revetement, be inclined or perpendicular. Nor does the corruption stop here; for many are in the habit of calling the berm the *escarpe*, and of confounding the covert-way with the counter-scarp; whereas neither the *escarpe* nor the counter-scarp have any thing to do with the *terre-pleine*, or level ground; but are applicable solely to the inclined faces of the ditch and ramparts respectively.

It is true that modern engineers, who often allow their phraseology to follow custom rather than etymology, make little, if any, distinction between such revetements as are inclined, and such as are perpendicular: not that many opportunities exist for indulgence in this error; there being very few walls or revetements intended for military works, and especially for the faces of parts subject to be battered, which have not a talus equal to at least one-sixth of their respective heights.

In some fortresses less reliance is placed on the artillery mounted upon the several works than upon the advantages afforded by the inclination of the *escarpe*. Thus, where a fort or redoubt is built upon a conical mound of rock, of which the interior may be excavated for lodging the defenders and their supplies, if the face of the cone be every where *escarped* to an angle of about 40°, or more, from the horizon, a very moderate perpendicular, say to the depth of seven feet, around the summit, will prevent any assailants, however numerous, from carrying the place by storm; provided that perpendicular be properly manned and supplied with large stones, perhaps from twenty to a hundred pounds weight, which being rolled down the *escarpe*, invariably precipitate all who may be in the line of their descent; such a defence is not to be overcome so long as vigilance is maintained, and a supply of stones is at hand.

In India, (as well as in other parts of the world,) small forts are often *escarped* on this principle; there the stones held in preparation for defence, all along the interior of the parapet, are designated "*Mut-wallahs*," (*i. e.* drunken men,) in allusion to the manner in which they roll, and in which those whom they overset are tumbled down to the plain below.

ESCARS, in *Geography*, a small town of France, in the department of the Upper Vienne; 15 miles S.W. of Limoges, which, before the French revolution of 1789, conferred the title of count on the lords of the manor.

ESCARTELE', in *Heraldry*, quartered, or quarterly. See QUARTERING.

ESCATALENS, in *Geography*, a small town of France, in the department of the Lot; 6 miles W. of Montauban.

ESCATARI,

ESCATARI, a small island about 5 leagues N. of Louisbourg, in the island of Cape Breton.

ESCATRON, a small town of Spain, in the province of Aragon, above the confluence of the Martin and Ebro, nearly opposite to Rueda, between Saragossa and Mequinenza.

ESCAUT, THE, more generally known in England by its Flemish or Dutch appellation of the *Scheldt*, or *Schelde*, was formerly a river of Austrian Flanders, and is now a river of France, which gives its name to one of the northern departments. It has its source in the department of the Somme, near Beaufort, a few miles to the north of Saint Quentin, a town of the department of the Aisne; runs by Beauvoisi, Catelet, Homécourt, Crévecoeur, Cambrai, Houdain, Bouchain, Neuville, Denain, Valenciennes, Fraine, and Coudé, where it becomes navigable, after having received the Aisne; it then flows to Mortagne, where it receives the Scarpe; from thence it goes on to Tournay, Gand, and Antwerp, where it is 701 metres, or 360 fathoms wide, and 10 metres, or 30 feet deep at low water; the tide at high water rises 15 feet. After having passed Antwerp, the Escaut branches out into two channels; the eastern one passes by Bergen-op-Zoom, the west channel, called the Upper Escaut, loses itself between the islands of Zealand into the North sea, near Fleissingue or Flushing. From Antwerp to this place its course is 74 miles; it widens gradually, and has pretty nearly the same depth every where; but its bed is obstructed by sand-banks, which render its navigation difficult and dangerous.

The Escaut has a communication with the river Somme by means of a canal, part of which is under ground.

ESCAUT, *the department of the*, is the ninth department of the first region or United Countries (*pays réunis*) of France, and derives its name from the river Escaut (*Schelde*) which traverses it from south to north. It is composed of part of Austrian Flanders; its chief place is Gand. The limits of the department of the Escaut are to the north, the kingdom of Holland; to the east, the departments of the Dyle and of the two Nethe, from which it is separated by the Escaut; to the south, the department of Jemmapes, and to the west, that of the Lys. Its principal rivers are the Escaut, the Lys, the Durenne, the Lièvre, the Dender, &c.

There are several canals in this department; that which goes from Gand to Bruges, and from Bruges to Ostend, is the most important. Another towards the north opens a communication between Rodenherpen and Sao-de-Gand; a third one, near Morbeck, communicates by one of its branches with Axel, and by the other with Hullt. There are also several lesser canals for the purposes of irrigation, or of draining low marshy grounds.

The soil is in general fertile, and produces all sorts of corn and vegetables, chiefly hemp, flax, and hops. It abounds in game. Domestic fowls and sweet water-fish are plentiful. The chief manufactures are those of linen yarn, linen cloth, cobalt, Prussian blue, ribbands, woollen cloth, earthenware, glass, writing paper. There are also several paper mills, sugar-houses, salt-works, and bleaching grounds.

The territorial extent of the department of the Escaut is 2888½ square kilometres, or 159¼ square leagues; its population 595,258, or 3720 inhabitants to the square league. The whole department is divided into four districts, Gand, Audenaërd, Termonde, and l'Écluse; 41 cantons, and 338 communes. The average contribution of every individual to the expences of the state is about 9*s.* 2*d.* sterling annually. Herbin *Statistique de la France*.

ESCAUT and *Meuse*, *the department of the*, in Dutch the department of the Schelde and Maas, is one of the new divisions of the kingdom of Holland, and is reported to comprise the western part of the ancient Dutch Brabant, Zealand, and the islands of the Maas or Meuse. Middleburg is its chief place.

ESCH, a town of the duchy of Luxembourg, on the Sour; 7 miles W. of Dicrich.

ESCH, in *Ichthyology*, a name given by Hildegard and others to the fish we call the grayling, or umber, and the generality of authors, the thymallus. It is of the coregonous kind, and is distinguished by Artedi by the upper jaw being longer, and the back fin containing twenty-three bones. The Germans call it *asch*, and the Italians *temello*. See *SALMO Thymallus*.

ESCHALLOT, *Cepa Ascalonica*, in *Botany*, a species of onion, cultivated in gardens for its use in cookery, and nearly resembling the Welch onion. See *CEPA*.

ESCHAR. This term, in *Surgery*, implies a portion of flesh, deadened by the application either of actual fire or caustic substances. In cases of violent burns we frequently see eschars produced; and whenever we wish to make a common issue, for the relief of any such disease as a white-swellings, a caries of the vertebrae, &c. we cannot accomplish our object better, than by forming an eschar with the kali purum cum calce vivâ. The separation of an eschar, or its detachment from the living parts, is a work of nature, being chiefly effected by the action of the absorbent vessels, which remove the particles of matter, connecting the dead and living parts together, so as to loosen the eschar, and allow it to be taken away, without pain, bleeding, &c.

ESCHARA, in *Natural History*, the name of a species of coralline, &c. the characters of which are these: they are of a stony or coral-like hardness, and resemble a woven cloth in their texture; and the microscope shews us that they consist of arrangements of very small cells, whose surfaces appear much in that form. (See *MILLEPORA*.) For other species, see *FLUSTRA* and *MADREPORA*.

ESCHAROPEPA, a word used by the old writers in *Medicine*, to express a coarse kind of barley-meal, which had been torried over the fire.

ESCHAROTICS, in *Surgery*, are certain substances and applications which, when put on any part of the body, occasion an eschar, or slough. Although the strict meaning of the word escharotic is the same as that of *caustic*, yet, modern practitioners usually understand by the first term some application that is milder in its action, than such substances as are denominated caustics. By the latter, a surgeon generally means the kali purum, with or without quicklime, or the argentum vitriatum, antimonium muriatum, &c. But by escharotics he commonly implies applications like the cuprum vitriolatum, hydrargyrus præcipitatus ruber, &c.

The chief use of escharotics, in the practice of surgery, is to destroy excrescences, funguses, and high exuberant granulations. When mixed with ointment, so as to have their action weakened, they are also sometimes employed for stimulating sores, which are of an indolent nature.

ESCHATON, in *Music*, the difference between the diesis enharmonica and the hyperoché; that is, what remains, after taking the difference between the semi-tone minor and diesis enharmonica, from the latter. Hensling, in *Misc. Berlin*. vol. i. p. 279, 280.

Thus the difference between the semi-tone minor and the enharmonic diesis is  $\frac{25}{24} : \frac{128}{125} = \frac{3125}{3072}$ , and this taken from

from the diesis, is  $\frac{128}{125} : \frac{3125}{3072} = \frac{393216}{390625} = 6\Sigma - f + m$ , and is the *major residual*; which see. This interval is about  $\frac{53}{100}$  of a comma, as will easily appear by logarithms. Mr. Henfling has taken notice of this interval. He calls it *eschaton*, from its being the least and the last interval that occurs in his system.

The word is Greek, *εσχάτων*. See INTERVAL.

ESCHATON of Dr. Callcott's MSS., is an interval whose ratio is  $\frac{16,677,181, \&c.}{16,777,216, \&c.} = 5\Sigma + 2f$ , and is the *greater residual*, which see.

ESCHE, in *Geography*, a town of Switzerland, in the canton of Uri; eight miles S.E. of Altorff.

ESCHEAT, ESCHET, or *Ecbet*, formed from the French *escheoir*, or *échoir*, to happen, in *Law*, denotes an obstruction of the course of descent, and a consequent determination of the tenure, by some unforeseen contingency; in which case the land naturally reverts back, by a kind of reversion, to the original grantor or lord of the fee. (1 Feud. 86. Co. Litt. 13.) This was one of the fruits and consequences of feudal tenure: and is incident to tenure in socage, as well as to tenure in knight-service; except only in gavel kind lands, which are subject to no escheats for felony, though they are to escheats for want of heirs.

The civilians call such escheats, or forfeitures, *bona caduca*; and in the same sense, as we say the fee is escheated, they say *feudum aperitur*.

The word *escheata* sometimes also signifies a lawful inheritance descending on the heir. But then it is usually distinguished by the addition of *reita*; as *reita escheata*.

ESCHEAT is also used for the place or circuit within which the king, or other lord, hath escheats of his tenants.

ESCHEAT is also sometimes used for a writ, lying where the tenant having estate of fee-simple, in any lands or tenements holden of a superior lord, dies seised without heir, general or special: in which case the lord brings this writ against him that possesses the lands, after the death of his tenant; and thereby recovers the same in lieu of his services.

ESCHEATOR, an officer who anciently took care of the king's escheats in the county, and certified them into the exchequer, or chancery.

He was appointed by the lord treasurer; held his office only for one year; nor could any person be escheator above once in three years. But this office, having its chief dependence on the court of wards, is now out of date.

ESCHEFELD, in *Geography*, a small town of Saxony, near Wolfftitz, in the circle of Leipzick, remarkable for its quarries of beautiful jasper, known by the name of Bandstein von Gnadstein.

ESCHEL, in *Mineralogy*, a term used by the smalt-workers, to express a sort of grey substance resembling ashes, which is usually mixed with the smalt when in fusion. This is carefully separated from it before it is powdered for use, otherwise it would deface the colour. Phil. Transf. N<sup>o</sup> 396.

ESCHELLON, or ECHELLON, in the military acceptation, is a term borrowed from the French language, in which it signifies a ladder; alluding to the regular and parallel gradations of any series of lines, more or less inclined from any given base line. Thus if we suppose in *fig. 1. Plate I. Tactics*, the line A B to be divided into any given number of equal parts, as 1, 2, 3, 4, 5, 6, and suppose the left end of each division to be moveable on a pivot, the other end

swinging round at pleasure, we shall find that those several divisions are capable of being moved forward, at the assumed angles from the base line A B.

Now it is necessary to be well understood, that, according to the military step, the number of files from any given pivot will determine the number of paces to be taken to make a wheel, corresponding with a right angle: thus when the 8th file from the pivot makes eight paces in wheeling, the whole of the division performing such evolution will make a wheel equal to the quarter of a circle, because all distances from the centre must invariably correspond with the quarter of a circle, of which such distances are respectively radius.

But the echellon movements are never understood to amount to the quarter of a circle; that being considered a full wheel, changing from line into column: yet the echellon is itself a species of column, disposeable with equal promptitude either to flank or front; thus affording peculiar advantage, while it gives at the same time a parallel movement of a line, broken for the moment, into small portions, towards any object obliquely situated towards either flank; in front or rear. These important advantages have not been overlooked by modern tacticians, who have amply availed themselves of the mutability thus afforded: consequently we find the echellon adopted in the existing code of evolutions, on an unlimited scale.

It being ascertained that the eighth file, by moving forwards eight paces in a regular curve on the given pivot, makes a wheel of one quarter of a circle; it is obvious, that any intermediate part, of which one pace is the multiple, may be wheeled, by taking the desired number of paces; thus, four paces will make an octave, or the eighth part of a circle, which is the most frequent declination from the base line; two paces will give the sixteenth of a circle, or the fourth part of a quadrant; and thus of any number.

Let us suppose it requisite to change the front of a battalion to a new position, forming, as nearly as the eye could estimate, an angle of 75° from the base line A B. Now, as each step of the eighth file gives a change of front equal to about eleven degrees, it is obvious, that seven ordinary paces will rather exceed the given angle; therefore, if very great precision should be indispensable, the eighth file should make six long, and one short pace, which would throw the whole battalion into echellon at such an angle as would allow the several divisions to march with a full front to their positions in the new line. This is a most important object; because it admits the utmost freedom of individual movement, and avoids that oblique tendency which must be referred to whenever such full frontage cannot be preserved.

Echellon may be formed towards either flank; whether to the rear or to the front; the open column may be readily formed by wheeling so as to complete the quarter of a circle, including the original portion, and adding it to the supplement: both wheels being in the same direction. Thus if only the eighth of a circle was wheeled into echellon, another wheel, of another eighth, will be needful to bring the corps into open column.

To form the line from echellon; either a back wheel may be made equal to the wheel forward: thus, if a battalion has broken into echellon by wheeling an octave to the right, it will, by wheeling back an octave on the right of divisions, be instantly formed into line. In this instance the right flank gives the point d'appui. But if the left is to give it, there the whole of the divisions must wheel forward on their left pivots, as many degrees as were included in the original wheel to the right. If the first wheel was only the

16th part of a circle to the right, the complementary wheel to the left must be equal to only one sixteenth. In saying this, it is necessary to be understood, that all the divisions are supposed to be of equal strength; otherwise it will be indispensably necessary that the respective pivots, which are to guide the alignment, be properly dressed; that is, cover correctly, before any wheel is made under their guidance.

Echelon divisions do not always move with a full front towards that point on which the wheel is made; on the contrary, it is often expedient to wheel to the right, when the new front is towards the left. This is done for the purpose of giving the flanks of the divisions a proper direction, that they may respectively march by files, towards their stations in the new line; and is particularly necessary in broken ground, as well as in countries covered with wood. The several leaders of files must, in this case, be extremely correct in maintaining their original direction; attending to their several pivot-men, if such be in fight: where that guide cannot be afforded, the greatest care must be taken to observe any two distant objects that may be in the given direction; so as to proceed, as nearly as possible, to the appointed spot.

From the foregoing it will be collected, that, while direct changes of front are made by full wheels (*i. e.* the quarter of a circle,) to either right or left, oblique changes are effected by means of a due degree of parallelism, produced in consequence of wheeling in any proportion less than the quarter of a circle. Therefore, as the code of regulations now in use for the movements of battalions properly inculcates, the echelon position and movements are not only necessary and applicable to the immediate attacks and retreats of great bodies; but also to the previous oblique or direct changes of situation, which a battalion, or a more considerable corps, already formed in line, may be compelled to make, to the front or the rear, or on a particular fixed division of the line.

When a battalion marches in echelon its route must be on the reverse principles of Marquis's parallel rule, which consists of a scale, having a triangular piece sliding at liberty along its edge, as shewn in *fig. 2.* In that the inclined plane A B even follows a line not perpendicular to its front, and this is the main distinction between the echelon movement and the oblique-step; the former may continue for any distance, rather giving ease, than proving unusually fatiguing, to the men; whereas the oblique-step is peculiarly distressing, if kept up for a length of time; while it besides possesses the great disadvantage of gaining but little ground. In the above figure the line A B may proceed the whole length of C D, without gaining ground towards its opposite, or exterior flank B; because it is, in a manner, fixed by the inner flank A, which may be said to run in a groove on the line B C; whereas if we applied the echelon movement to the line A B, that is perpendicular to its own front, its course would be according to A E, B F, and ground would be gained to its right, as well as to its front, in exact proportion to the angle D A B; if that be small, there will be a greater tendency to the front of the line C D, than towards its left flank, and *vice versa*; ever carrying in mind, that so soon as the wheel amounts to a quarter of a circle, the term echelon is annulled.

We shall here exhibit the use of an echelon movement as applicable to the reinforcing of a line advancing at the *debouchure* of a *detroit*; where, in consequence of the regular expansion, it becomes necessary to keep adding to either, or perhaps to both flanks, in order to prevent the enemy from penetrating; so as to attack the rear. It may be expedient to observe that not only companies, but whole battalions,

may form in echelon; and that it is an evolution suited equally to cavalry and to infantry. When a park of artillery has to flank an enemy, in a position where the proper line cannot be assumed, so as to bring the several guns to a line perpendicular to the direction of their fire, they must then, properly speaking, be individually in echelon. Thus when guns are mounted in *barbet*, (*i. e.* where there are no embrasures, the muzzles traversing over the parapet,) whenever the object does not bear at right angles with the face of the battery, each gun is obliqued, and the shots fired from the whole would represent the movements of divisions thrown into echelon. *Fig. 3.* shews a line forming as the army issues from a *detroit*, the several battalions composing it being allowed to reinforce the centre until due space be gained for the whole to wheel into echelon. Now it will be seen, that each battalion formed in column, in by files, successively assumes a position perpendicular to that line; but, that when space admits, the wheel is made, whereby each division is directed towards the post it will occupy on the flank, as the expansion takes place. Here S S is the line, and O P the battalion destined to cover the right flank; its several divisions, being thrown into echelon, must in their progress fall into their respective posts, at the new position *a a* one after the other, filling up the augmenting space with celerity and exactness. It is, however, to be understood, that each, as it approaches its situation in line, must accelerate or retard its pace according to circumstances; since it cannot be expected that the ground will expand with perfect regularity.

In case of an attack, in which the enemy may succeed in getting round the flank, those divisions close to that flank must wheel back into line; leaving to two or three of the rear divisions to join on their flank in the direction of the echelon front; thus forming a re-entering angle, effectually cutting off the enemy's progress, and subjecting him to a concentrated fire; as shewn by the dotted positions at E. The dotted lines emanating from the several echellons shew their direction when marching: their prolongation would shew how they would fall in on the flank, so as gradually to extend the front; completing the new line *a a*. When necessary, the same operation is performed towards the left.

It has been observed that the eighth file gives a determinate measurement, in regard to the wheel of divisions into echelon; it is therefore expedient, when the given direction is ascertained, to cause the eighth file to step out the required distance, (say four paces for the eighth of a circle,) observing, that his advance must be on a wheeling principle: that is to say, curved; the pivot being considered as the centre, and the distance between that and the eighth file being radius. Each division thus sending forth its eighth file, the whole are ordered to wheel until those files are restored to their places in their divisions: during the wheel of the divisions, each must necessarily remain motionless; that all may dress by them; so as to give a true parallel throughout the line of echelon.

ESCHENAU, in *Geography*, a town of Germany, in the archduchy of Austria; eight miles S. of St. Polten.

ESCHENBACH, a town of Germany, in the circle of Bavaria, and Upper Palatinate; 34 miles E.N.E. of Nuremberg.

ESCHENBERGA, a small town of Germany, in the duchy of Saxe Gotha, with a population of 504 inhabitants, remarkable for its trade in madder. It was anciently of more importance.

ESCHERSHEIM, a town of Germany, in the circle of the Upper Rhine, and county of Hanau-Munzenberg;

10 miles W. of Hanau, and 3 N.N.W. of Francfort on the Main.

ESCHEVIN, or ECHEVIN, *Scabinus*, in the French and Dutch *Polity*, a magistrate elected by the inhabitants of a city to take care of their common concerns, the good order, conveniency, and décoration of the city, &c.

At Paris there is a *prevot* and four *eschevins*; in most other cities a *maire*, or *mayor*, and *eschevins*. In *Languedoc*, *Provence*, and *Dauphiné*, they are called *consuls*; at *Thoulouse* *capitouls*; and *jurats* at *Bordeaux*.

Anciently, the *eschevins* were the assessors and counsellors of the *comites*, or judges of cities; on which account they were called, in some places, *pairs*, *pairs*; they even took cognizance of petty causes themselves.

Du-Cange observes, that the judges, and their assessors, who were chosen by the inhabitants, were called *scabini*, *eschevins*, and their college, *scabinatum*, or *eschevinage*. He adds, that some authors call them *pacarii*, because their office and jurisdiction extended to the securing peace in their city and banlieue, called *pax villa*.

In *Holland*, the *scabins*, or *eschevins*, judge of all civil affairs at first hand. They also take cognizance of criminal matters; and if the criminal confess himself guilty, they can see their sentence executed without appeal. They can even give torture. The number is not the same in all cities; at *Amsterdam* there are nine, at *Rotterdam* seven, &c.

ESCHLBERG, in *Geography*, a town of Germany, in the archduchy of *Austria*; 14 miles S.W. of *Freustadt*.

ESCHLKAMP, a town of Germany, in *Lower Bavaria*; 3 miles E. of *Furth*.

ESCHRAKITES, or ESRAKITES, a sect of philosophers, among the *Mahometans*, who adhere to the doctrines and opinions of *Plato*.

The word is derived from the Arabic *شراک*, *schraha*, which in the fourth conjugation *شراک*, *aschraka*, signifies to shine, glitter like the sun; so that *Eschrakite* seems to import illuminated.

The *Eschrakites*, or *Mahometan Platonists*, place their highest good and happiness in the contemplation of the *Divine Majesty*; despising the gross imaginations of the *Alcoran* touching *Paradise*. See *MAHOMETANISM*.

They are very careful in avoiding all vice; they preserve an equal and easy temper, love music, and divert themselves with composing little poems, or spiritual songs. The sheiks, or priests, and the chief among the preachers of the imperial mosques, are *Eschrakites*.

ESCHWEGE, in *Geography*, a small town of Germany, in the *landgraviate* of *Hesse Cassel*, which now forms part of the new kingdom of *Westphalia*. It is situated on the *Werra*, 33 miles E. of *Cassel*, near a lofty hill called the *Meisner*, which has some coal-mines. *Eschwege* is a place of high antiquity.

ESCHWEILLER, a small town of France, in the department of the *Roer*, chief place of a canton, in the district of *Aix-la-Chapelle*, with a population of 1713 individuals. The canton has 18,588 inhabitants, dispersed in 28 communes.

ESCHYLUS. See *ÆSCHYLUS*.

ESCHYNOMENOUS PLANTS. See *ÆSCHYNOMENOUS*.

ESCLAIRCISSEMENT, or ECLAIRCISSEMENT, a French term, which we find retained in some late English writers; it properly signifies the act, or effect, of clearing a thing, or rendering it more bright and transparent; being formed from the verb *esclaircir*, to clear, &c.

It is chiefly used in a figurative sense, for an explanation of an obscurity or difficulty. The *esclaircissement* of difficult passages in the bible, is to be sought for from similar passages, or passages of the like kind occurring in other places.

ESCLAME, in the *Manege*, an obsolete French word, formerly used to signify a light-bellied horse.

ESCLATTE, in *Heraldry*, is applied to a thing violently broken. Thus a bend or rather partition, *esclatté*, is represented torn, or broken off, like a shield shattered with the stroke of a battle-ax.

ESCOBAR, ANTHONY, surnamed *D: Mendoza*, in *Biography*, a Spanish Jesuit, who flourished in the beginning and middle of the seventeenth century. The opinions which he maintained have been censured by more modern writers; and the principles of his morality have been exposed by *Paschal* in his "Lettres Provinciales," and by other authors of less note. He left behind him many works, among which are "Theologia Moralis;" "Commentaria in Vetus et Novum Testamentum;" and "Examen y Pratica de Confessores." Moreri.

ESCOL, in *Ancient Geography*, a valley or torrent of *Palestine*, in the southern part of the tribe of *Judah*; mentioned in the book of *Numbers*.

ESCORT, in *Military Affairs*, signifies that guard granted, either under military authority, or of military persons, for the safe conveyance of persons, property, &c. from one place to another. This may be said to distinguish an escort from a convoy; the latter being generally applicable to such extensive affairs as relate rather to the guarding of supplies, &c. on their way to an army, or to a fortress. The extent of an escort is usually proportioned either to the dignity of the person attended, if it be meant as a compliment; or, if of treasure, according to the sum, and the dangers lying in the way. In some cases, escorts are taken only from particular corps; as, for instance, those which attend upon his majesty, which are selected from certain regiments only, unless on extraordinary occasions. When an escort is employed on such an occasion, its commander is usually placed under the orders of the person to be guarded; but when treasure, prisoners, &c. are in question, the commander is in every respect paramount; he being responsible for the safe arrival, and the delivery, of whatever is under his charge. Such is the strictness with which the responsibility of an escort is upheld, that a few years back, when a deserter who was under charge of a guard made an attempt to abscond, one of the party fired at him, but unhappily missing the fugitive, killed an unfortunate passenger in the same street; the man who fired was considered to have done no more than his duty. We naturally view such an occurrence with much concern, and commiserate the sufferer; but when we contemplate what might have been the situation of the soldier, had he omitted to do his best towards preventing the escape, though we cannot exactly applaud his conduct, we must assuredly see much in extenuation of the manslaughter.

When travelling any distance, and that speed is essential, it is usual to relieve the escorts, when convenient, at certain stages. In such case, it behoves the commander of each party to be very careful in examining every matter previous to taking charge. If there be treasure, or other valuables, &c. under seal, the impressions should be minutely inspected; and if the articles, or packages, be numerous, but more especially if subject to damage, he should cause the whole to be counted, and ascertain, in the presence of the persons from whom he receives them, the exact state and appearance, noting every point worthy of observation in the way-

bill, and exclusively giving a receipt, in which all casualties or deficiencies should be fully described. This inspection should always be made in the presence of others of his own party, and it would not be amiss were he to cause them to attest the condition in which the articles should be, at the time of his receiving charge. Should any accident take place while under his own protection, the hour, the place, and the cause, ought to be in like manner noted, so soon as possible, under the certificate of credible persons on the spot; or at least of some of his own party. By such precautions much imputation will be avoided; while at the same time a character for correctness, and for assiduity, will be gained.

ESCOT, L', in *Geography*, a small town of France, in the department of the Lower Pyrenées; 6 miles S. of Oleron, remarkable for a cooling mineral spring.

ESCOUADE, or SQUAD, is usually the third or fourth part of a company of foot; so divided for mounting guards, and for the more convenient relieving of one another. It is equivalent to a brigade of a troop of horse. See BRIGADE.

ESCROL, or SCROLL, in *Heraldry*, a long slip, as it were, of parchment, or paper, wherein a motto is placed.

Leigh observes, that no person, under the degree of a knight, might, long after king Henry V. place his crest on a wreath, as is now usually done, but only on an escrol.

ESCROW, in *Law*, a deed delivered to a third person, to be the deed of the party making it upon a future condition when such thing is performed; and then it is to be delivered to the party to whom made. It is to be delivered to a stranger, mentioning the condition; and has relation to the first delivery. 2 Roll. Abr. 25, 26. 1 Inst. 31. See DEED.

ESCU, or ECU, the French crown, of sixty sols, or three livres. The escu was thus called, because the escutcheon, or arms of France, which they call escu, was struck thereon. See COIN.

ESCU, *Emaux de P.* See EMAUX.

ESCUAGE, or SCUTAGE, an ancient kind of knight's service, called also "service of the shield;" the tenant holding by which was obliged to follow his lord to the Scottish or Welsh wars, at his own expence. But personal attendance being inconvenient, the tenants compounded for it by a pecuniary satisfaction, which was levied by assessments at a certain rate for every knight's fee; and thus it became a pecuniary in lieu of a military service. The first instance that occurs was in 5 Hen. II. on account of his expedition to Toulouse; it afterwards became more general and oppressive; so that king John was obliged to consent, by his Magna Charta, that no scutage should be imposed without consent of parliament; but the clause was omitted in the charter of Hen. III. which directs, that it should be taken as it is used to be in the time of Henry II. or in a reasonable and moderate manner. However, it was afterwards enacted by stat. 25 Edw. I. cap. 5 and 6. and many subsequent statutes, that the king should take no aids or tasks but by the common assent of the realm; and it appears that scutages were the ground work of all succeeding subsidies, and of the land-tax of later times. Blackst. Com. vol. ii. p. 74.

ESCUAGE was also a reasonable aid, demanded by the lord of his tenants, who held of him by knight's service. See AID.

"Concesserunt domino regi ad maritandum filiam suam de omnibus qui tenent de domino rege in capite de singulis scutis 20 solidos solvendo." Matt. Paris, anno 1242.

VOL. XIII.

ESCOLAPIUS. See ÆSCULAPIUS.

ESCULENT, in *Gardening*, is a term frequently applied to such roots or plants as are replete with nutritious matter, and consequently proper for being eaten as a food. Carrots, parsnips, turnips, cabbages, and various others of a similar nature, are of this kind.

ESCULUS, in *Botany*, a name given by many authors to the phagus, or sweet oak, called also the esculent oak.

ESCULUS, or Æsculus. See ÆSCULUS.

ESCURA, in *Geography*, a province of the empire of Morocco, called by Leo Africanus *Afscora*, which, together with that of Ramna, formerly composed only one government. It has been divided to keep the people of these countries, so near to the mountains, more easily in subjection. Ramna and Escura have the province of Morocco to the south, that of Duquella to the west, the river Morbeya to the north, and mount Atlas to the east.

ESCURIAL, by the Spaniards written *Escorial*, a term that denotes the place of residence of the kings of Spain. Escorial originally signifies a little village in Spain, situated in the kingdom of New Castile, 22 miles to the N.W. of Madrid, on the side of a chain of mountains, called by some the Carpetane, or Carpentanian mountains, and by others the Pyreneans, as being the branch of the Pyrenean ridge, and environed by woodlands and green fields. Here king Philip II. built a stately monastery of the order of St. Jerom, held by the Spaniards for one of the wonders of the world; and called the Escorial. It was begun in 1557, and finished in about twenty-two years, at the expence of six millions of piastres.

Fa. Francisco de los Padros, in a description thereof, intitled "Description breve del Monasterio de S. Lorenzo el real del Escorial, &c." assures us it was built by that prince in memory of the battle of St. Quintin, gained on the day of St. Laurence, Lorenzo, a famous Spanish saint, and at his intercession; accordingly the plan of the work resembles a gridiron, the instrument of the saint's martyrdom.

The king and queen have their apartments there; the rest being possessed by the monks. Whence many of the great transactions of that court are dated from the Escorial.

This superb palace is a long square, 740 by 580 Spanish feet, besides 460 for what may be termed the handle of the gridiron. The height of the roof is 60 feet; and at every angle is a square tower, 200 feet high. In the west front there are 200 windows, and 366 in the east.

The Escorial has a very fine church, the dome of which is 330 feet, supported by four rows of pillars, and paved with black marble, containing 40 chapels, and 48 altars. To this church Philip IV. annexed a beautiful mausoleum, called the Pantheon, or Rotondo, built on the plan of that temple at Rome, 36 feet in diameter, and incrusted with marble; in which the kings and queens of Spain, who leave any posterity, are interred; the rest being laid in another vault of the same church, together with the infantas, and other princes.

The palace possesses every convenience and ornament that can render a place agreeable in so hot a climate; such as an extensive park, groves, fountains, cascades, grottos, &c. The adjacent country contains specimens of all the mineral substances, stones, earths and vegetables, which are found in other parts of the kingdom. The library belonging to this palace is said to consist of 30,000 volumes, contained in two magnificent apartments, each 19½ Spanish, or somewhat more than 182 English feet in length. In the lower room are chiefly printed books; and in this is deposited the

famous MS. of the four gospels, written in gold letters, said to be a work of the 11th century. Over these are collected 4500 MSS., of which 567 are Greek, 67 Hebrew, 1800 Arabic, the latter of which are well described in a catalogue published by Casiri. In the middle of the lower room is a temple, with a great variety of figures, containing 1448 ounces of silver, and 43 of gold, besides rich gems. In every part of the convent of the Escorial, are seen the works of the best masters, and some of them most capital performances. The best of the pictures are collected in five principal apartments; the great staircase is beautiful, adorned with fresco-paintings of the battle of St. Quintin, by Luca Jordano. The situation of the Escorial, as a residence, is not pleasant: exposed, as it is, to the full stroke of the meridian sun, and raised up near to regions covered with eternal snow; without shelter and destitute of shade, it has no local charms at any season of the year. (Townsend's Travels, vol. 2.) Part of this superb palace was burnt in 1671.

ESCUROLLES, in *Geography*, a small town of France, in the department of the Allier, chief-place of a canton, in the district of Gannat, with a population of 1042 individuals. It is 6 miles N. of Gannat. The canton contains 15 communes, and 11,408 inhabitants, on a territorial extent of 237½ kilometres.

ESCUTCHEON, or SCUTCHEON, in *Heraldry*, the field or coat, wherein the bearing, or arms, of any person are represented.

The word escutcheon is formed of the French *escuffon*, and that from the Latin *scutum*, shield; which was the place arms were originally borne on, before ever they came on banners; and still, wherever they are placed, it is on something representing the form of a shield. The Latin *scutum*, no doubt, came originally from the Greek, *σκιον*, leather, wherewith the shields were usually covered. See SHIELD.

The escutcheon is of a square figure, excepting the bottom part, which is usually a little rounded, ending in a point in the middle.

Till within a few hundred years, the escutcheons of the French and English were triangular; those of the Spaniards are still quite round at bottom, without any point; those of the Italians are oval; and those of the Germans in form of a catoozes.

The ancient escutcheons were generally couched, or inclined; and they only began to place them upright, when crowns, &c. were put over them by way of crest.

In France *escuffon*, escutcheon, was formerly restrained to a shield, or coat, pointed at bottom; by which it was distinguished from the *escu*, which was quite square, and was only allowed to be borne by the counts and viscounts. Those of the inferior quality were confined to the *escuffon* or pointed *escu*.

The several parts or points of the escutcheon have their proper names: the point A, for instance, is the dexter chief point; B the middle chief; and C the sinister chief point; D is the honour point; E the fesse point; F the nombril point; G the dexter-base; H the middle; and I the sinister base point. See *Plate of Heraldry*.

The dexter side of the escutcheon answers to the left hand, and the sinister side to the right hand of the person that looks on it.

The escutcheon is differently denominated, according to its divisions. It is called dextered, when the perpendicular line that divides it is to the right of a third part of the escutcheon; sinistered, when on the left; tierced in pale, when this line is double, and divides the whole escutcheon

into three equal parts; pale, when increased to the number of six, eight, or ten. A horizontal line makes the chief, when at one third part from the top; the plain, when at a third from the bottom; and when double, in the middle at an equal distance from both extremes, it makes the fesse, and the tierced in fesse: when it is multiplied, it denominates it fessed; when there are eight or ten equal spaces burrelle. A diagonal from the dexter point of the chief to the sinister of the base, makes it tranché; the contrary double; if it be double at equal distances the first makes bandé, and the tierce in bend; and the other barre, or tierce in bar; increasing the number of the first makes bandé, and cotticé; and increasing that of the second barré, and traverse.

ESCUTCHEON of *pretence*, is an *inescutcheon*, or little escutcheon, which a man who has married an heiress, and has issue by her, may bear over his own coat of arms, and in it the arms of his wife; and, in this case, the surviving issue will bear both coats quarterly.

ESCUTCHEON, in *Sea Language*, a name sometimes given to the compartment for the names or arms of the owner, or of the person whose title the vessel assumes. It is usually fixed on the middle of the ship's stern; and is more peculiar to the French, and other foreigners, than to English-built vessels. Falconer.

ESCUTCHEON, *Secret*, is a contrivance to be placed before a lock, which closes up, and conceals the key-hole, and renders it inaccessible for any person except the owner, who is acquainted with the secret.

The marquis of Worcester appears to have invented some secret escutcheons, for in his "Century of Inventions," published in 1663, at N<sup>o</sup> 72, after having spoken of three kinds of locks invented by him, says, "an escutcheon to be placed before any of these locks with these properties:

"The owner, though a woman, may with her delicate hand vary the ways of coming to open the lock ten million times beyond the knowledge of the smith that made it, or of me who invented it."

Many attempts have been made to form a machine equal in its properties to the description here given; and from thence, it is probable, arose the kind of padlocks which have been long made in this country, in great numbers, which having several letters on different rings, can only be opened when a certain set of those letters is arranged in one order; but this was in no degree equal to the end proposed; for besides the workman who made it, being at all times informed of the position the letters must be in, and consequently enabled to open it, the letters and rings admitting of no variation of place, at the will of the owner; reserving, at the same time, a power of opening the locks; whenever the proper arrangement became known, the secret was divulged, and all security at an end; but by the improvement lately made by Mr. Marshall (for which the Society of Arts rewarded him with ten guineas,) the letters or figures allowing an almost infinite variety of changes, the owner may, in one minute, alter the secret in such a manner, that even the maker would be as unlikely to open it, as he would be of gaining the highest prize in a lottery, by the chance of a single ticket. Thus this kind of escutcheon is infinitely more secure than any hitherto in use, especially as the alteration of the letters may be made every day for years, without recurring to their first state; and as the owner may at one time chuse to trust a friend, or a domestic with the secret, so that they might have recourse to his valuables, &c. he may also at another time wish to exclude them from that privilege, which this contrivance renders very easy to be done. As this improvement relates only

to the escutcheon, it is obvious that every attempt to pick the lock it covers, or to open it by means of false keys, is prevented; a circumstance of no small importance, when locks of a curious construction, and when a number of fine wards are made use of.

The escutcheon for which the bounty was given is reserved in the repository of the society for the inspection of the public.

*Figs. 2, 3, 4, 5, 6, 7, 8, and 9, Plate XII. Miscellany,* represent this contrivance: *fig. 3.* is a view from behind the machine, supposing it to be first removed from the door. *Fig. 2.* is an elevation of the machine, as it appears upon the door; A B C D is a brass box, fastened over the key hole; it has a square hole through it, covered by a small door E; this door is kept shut by a pin fixed into a small lever *a*, *fig. 3.* which enters a projection from the side of the door, and thus prevents it being open, unless the lever is first drawn back; a spring *b* is applied behind the lever to force it outward, and another at E always presses against the door, and acts to throw it open as soon as the lever *a* is drawn back, which is accomplished by means of a pin, which comes through a groove in the plate; this pin is fastened in a square bar F, *figs. 2 and 5.* (shewn separately in *fig. 4.*) on the front of the plate. The small perspective, *fig. 8.* represents two brass cocks *d, d*, which support the ends of a cylindric wire *g*, in which is a groove for the bar F to slide backwards and forwards; these cocks are screwed to the plate within-side, as shewn at *d d*, *figs. 2, 3, and 5,* and come through an opening in the Plate; so that the bar F is in front of the plate; the wire *g* is the common axis for five small rollers *a, c, f, m, o*, the structure of one of these is explained by *figs. 5, 6, 7, and 9;* *b* is a circular piece of brass which fits upon the centric wire: this, as is shewn in the sections, *figs. 5 and 9,* is thicker at the outside than the middle; and the front view, *figs. 6, 7,* shew how a recess is cut, communicating with the centre hole; now when the five rollers are turned round upon the central wire *g*, so that the recesses are all brought into the front, the projecting teeth *x, x*, of the slider F will meet with no obstruction, and may be drawn back so as to open the escutcheon; but when any of the rollers are turned round, so that the thin parts near the centre are brought between the teeth of the slider, then the slider cannot be withdrawn. The position of the roller, when the slider is at liberty, is known by bringing five of the letters which are engraven on the outside of the rollers uppermost, and it is in these letters that the secret consists. But to render the combination of letters variable, the letters are not engraven upon the outside of the rollers themselves, but upon a thin brass hoop *e*, which is fitted on round the roller; a spring *n* is fastened to the roller, and pressing upon the inside of the hoop causes such a friction, that they go together in general; but when the secret is to be changed, the slider F must be drawn partly back, so that its teeth *x* come in the way of the thin parts of the rollers, and they cannot, therefore, be turned round; the outside hoop *l* is then forced round upon the inside one, and a fresh letter brought opposite the recess; by this operation the secret is altered, and the escutcheon cannot be opened till the same combination is produced. Each roller has four letters upon it, in all twenty letters, and the combinations which they are capable of are so numerous, that the chance is strongly against any person not acquainted with the secret opening it.

ESCUTCHEON-grafting. See GRAFTING.

ESDEN, in *Geography*, a town of Germany; in the kingdom of Westphalia, and bishopric of Liege; 3 miles S.S.W. of Stocklin.

ESDRAELON, or ESDRELA, in *Ancient Geography*, a village of Palestine, in the tribe of Issachar, the same as Jezreel, 10 miles from Scythopolis, according to the old Itinerary. (Josh. xix. 18.) It gave name to a plain, which extended east and west from Scythopolis to mount Carmel; called likewise the "Great Plain," the "Valley of Jezreel," and the "Plain of Esdrela."

ESDRAS, See EZRA. We have four books of scripture under the name of Esdras; of which, only the two first are acknowledged as canonical; and they were formerly reckoned by the Hebrews as one, according to St. Jerom. The first of these is allowed to be the work of Ezra; for he relates events of which he was witness, and often speaks in the first person. Some, however, have supposed that the six first chapters were composed by a more ancient writer; and they allege, that the author of these chapters was at Jerusalem in the time of Darius the son of Hytaspes. (Ch. v. 4.) From this passage it is inferred that the writer was then at Jerusalem; but Ezra did not come thither till the reign of Artaxerxes, as appears by the beginning of the 7th chapter. To this argument it is replied, that Ezra speaks in the name of the Jews, and that it is usual for historians of a country to speak in the first person in the name of their own nation, although the historians themselves had no participation in the events which they record. Another difficulty occurs in explaining the genealogy and number of those who returned from Babylon to Jerusalem under Nehemiah, mentioned in the second chapter, and related in the same manner, though with some additions and alterations in the 9th chapter of Nehemiah. Some suppose that Nehemiah transcribed this out of the book of Ezra, adding the names of those persons who came to Jerusalem in the second return from the captivity. Others, on the contrary, imagine that Ezra copied the passage from Nehemiah, since mention is made in it of Nehemiah. Others pretend that the genealogy of Ezra was afterwards corrected from that of Nehemiah. However, none of these conjectures are reconcileable with the differences that occur in the two genealogies. But after all, there is no necessity for supposing that one of these authors transcribed from the other, for they might both of them have written these genealogies: Ezra having survived the second transmigration made under Nehemiah, and not having written his book till the latter end of his life. The second book under the name of Ezra, is attributed to Nehemiah; though some inconsiderable particulars have been added to it, which cannot belong to Nehemiah: such as the mention of the high-priest Jaddua, and king Darius. (Neh. xii. 22.) This Jaddua is Jaddus, in whose time Alexander the Great came to Jerusalem; and Darius is Darius Codomannus, overcome by Alexander 100 years after Nehemiah. The first of these two books contains the history of the deliverance of the Jews from the captivity of Babylon, and of their re-settlement in Judea, from the first year of Cyrus to the 20th of Artaxerxes Longimanus; and the second begins at the 20th year of the same prince, to the reign of Darius Nothus. The chronology of this space of time depends on the duration of the reigns of the kings of Persia.

The third book, under the name of Esdras, is thought by the Greeks to be canonical. Its author is not known, but he is supposed to have been an Hellenist Jew. The book is the same in substance as the first of Esdras, but interpolated; and in different parts of it we have a summary repetition of the two last chapters of the second book of Chronicles, as well as of the books of Ezra and Nehemiah. Against its authority there are several material objections, for which we refer to Arnald's excellent Commentary on the Apocrypha, p. 122.

The fourth book of Esdras is written with sufficient art, as if Esdras himself had composed it; but the marks of falsehood are discernible in it. Neither the Synagogues, nor the Greek or Latin church ever unanimously received it as canonical; though some of the fathers have cited it, and the Latin church has borrowed some words out of it. It is not now extant in Greek; and it never was in Hebrew. It seems most probable that the author was a Jew, converted to Christianity, who, in hopes of converting others, composed this work under the name of a writer, for whom the Jews had the highest esteem. And there seems good reason for concluding that the author lived in the times of the first heathen persecutions, from many passages encouraging faith, and a spirit of constancy under persecution.

ESEBON, a name given, by some of the chemical writers, to common sea salt.

ESENS, in *Geography*, a town of Germany, in the kingdom of Westphalia, and county of East Friseland; 24 miles N.N.E. of Emden.

ESFARAIN, a town of Persia, in the province of Chorasfan; 80 miles E. of Asterabat.

ESGÚEVA, a river of Spain, which runs into the Pisuerga, at Valladolid.

ESGUEYRA, or ESGUERIA, a town of Portugal, in the province of Beira, containing about 1600 inhabitants; 8 miles S. of Aveiro.

ESH, in *Rural Economy*, a term provincially employed to denote the ash-tree.

ESHANESS, in *Geography*, a cape on the west coast of Main-land, the largest of the Shetland islands. N. lat. 60° 38'. Long. 1° 7' E. of Edinburgh.

ESHCOL. See ESCOL.

ESHTAOL, in *Ancient Geography*, a town of Palestine, in the tribe of Dan, which belonged first to Judah. According to Eusebius it was 10 miles distant from Eleutheropolis, towards Nicopolis.

ESHEMOTH, a city in the south of Judah, which, according to Eusebius, was a large town in the district of Eleutheropolis, north of that city. It was ceded to the priests. 1 Chron. vi. 57.

ESI, in *Geography*, a town of Italy, in the state of the church, and marquise of Ancona; 11 miles S.S.W. of Ancona.

ESK, SOUTH and NORTH, rivers of Scotland, which descend from the Benakinnan mountains on the north border of Angus. The former runs S.E. and E. by Cortachie, Tannadyce, Brechin, and falls into the German ocean below Montrose, to which town it is navigable from the tide-way in the German ocean. (See CANAL). The direction of the latter is E. and S.E. through a narrow valley, till it reaches the strath lying between the Grampians and the sea. In the lower part of its course it forms the common boundary of Angus and Kincardine.

ESK, a river in Cumberland, which is navigable from the Solway firth up to the town of Longton.

ESKARMAKRUN, a town of Persia, in the province of Chusistan; 90 miles S. of Susa.

ESKE, a river in the East Riding of Yorkshire, which is navigable only from the sea up to Whitby-bridge. See CANAL.

ESKE, a river in Cumberland, which is navigable from the sea near Ravenglass to Mulcafter. Near to Ravenglass it is joined by the Irt river.

ESKER, a river of European Turkey, which runs into the Danube; 20 miles W. of Nicopolis.

ESKI-BABA, a town of European Turkey, in Romania; 30 miles S.E. of Adrianople.

ESKIER, a town of Arabia, in the country of Yemen; 60 miles N. of Aden.

ESKIJALFA, a town of Persian Armenia, in the country of Erivan; 120 miles S. E. of Erivan.

ESKI-HISAR, a town of Asiatic Turkey, in the province of Natolia; 16 miles W. of Mogla.

ESKI-HISSAR, a town of Asiatic Turkey, in the province of Natolia, formerly Laodicea, now almost a heap of ruins; 8 miles N. of Degnizlu.

ESKIMAUX, or ESQUIMAUX. See ESQUIMAUX and LABRADOR.

ESKIMAUX Bay, a bay on the south-coast of Labrador. N. lat. 51° 30'. W. long 57° 50'.

ESKIMAUX Islands, a cluster of small islands in the gulf of St. Lawrence, near the south-coast of Labrador. N. lat. 50° 15'. W. long. 63°.

ESKISADRA, a town of European Turkey, in the province of Romania; 48 miles E. of Filippopoli.

ESKISHEHR, a town of Asiatic Turkey, in the province of Natolia, on the river Sakharra; 116 miles S.E. of Constantinople. N. lat. 39° 48'. E. long. 32° 58'.

ESLA, a river of Spain, which runs into the Duero, between Zamora and Miranda de Duero.

ESLINGEN, a town of Germany, in the circle of Suabia, which, till the peace of Luneville, was a free imperial city. It now belongs to the king of Wirtemberg, and is situated on the Necker, 30 miles N. E. of Tubingen, and 6 miles S. E. of Stutgard.

ESMONA, or AZEMONA, in *Ancient Geography*, a town of Arabia Petraea, which was one of the stations of the Israelites in the Desert. The book of Joshua ascribes it to the tribe of Juda, so that it is probably the same with *Esem*.

ESMOUTIER, in *Geography*, a small town of France, in the department of the Upper Vienne; 21 miles E. of Limoges.

ESNA, in *Ancient Geography*, a town of Palestine, in the tribe of Juda. Josh. ch. 15.

ESNECY, *Æsnecia, dignitas primogeniti*, in *Law*, a private prerogative, allowed to the eldest coparcener, where an estate has descended to daughters for want of heirs male, to chuse first after the inheritance is divided. Fleta, lib. v. cap. 10. "Jus esnecie is jus primogenituræ," in which sense it may be extended to the eldest son, and his issue, holding first. In the statute of Marlbridge, cap. 9. it is called "initia pars hereditatis."

ESNEH, *Èsné, or Asna*, in *Geography*, one of the most important towns in Upper Egypt, seated on the left of the Nile, in N. lat. 25°. E. long. 49° 15'. This town is governed by an Arabian prince and by a Cachef, dependent on the Bey of Girgé. The Mahometans have several mosques here, and the Copts a church, that is served by two priests. According to the description of Abulfeda, which corresponds in a great degree to its present state, Esné is remarkable for its public baths and its commerce: it is built on the westward of the Nile, between Assuan and Cous, but nearer to the latter. The Copts are said to be its founders. The well-cultivated territory abounds in grain and palm-trees. Situated on the edge of a rich country it is shaded by groves of orange-trees loaded with fruits and flowers, and immediately surrounded with gardens amply stocked with fruit-trees. It presents to view several ancient monuments constructed by the Copts, and superb ruins. This town, formerly called *Latopolis*, revered Minerva and the fish *Latus*. (Strabo, l. 17.) It contains within its boundary an antique temple, enclosed on three sides by thick walls. Six large fluted columns, crowned by a capital, ornamented with the palm leaf, form the façade of it; eighteen others support the roof; which is

composed of large squares of marble; the building is surrounded by a frieze, and innumerable hieroglyphics cover its exterior aspects. Those of the inside, executed with greater care, mark the progress made by the Egyptians in sculpture. These hieroglyphics contain, among other subjects, a zodiac and large figures of men with crocodiles' heads; the capitals, though all different, have a very fine effect; and as an additional proof that the Egyptians borrowed nothing from other people, it is remarked, that they have taken all the ornaments, of which these capitals are composed, from the productions of their own country, such as the lotus, the palm-tree, the vine, the rush, &c. The portico of this temple is represented by M. Denon, (*Travels in Egypt*, vols. 2. and 3.) as the most perfect monument of ancient architecture. Denon has given a plan and elevation of this portico, and delineated the varieties of its capitals, and part of the sculptures on the ceiling; but he was surprised that, after all his research, he could find no representation of the fish *latus*, from whose name the town was called *Lato-polis*. At present this temple is soiled by the ordure of the cattle kept there by the Turks, who convert the most beautiful monuments of ancient Egypt into stables. About a league to the west of Efné is another temple, on the walls of which is carved in several places a woman seated, representing an Egyptian deity called "Neith," to whom the ancient Greeks gave the name of Minerva. The columns of this temple, as some have conjectured, gave to the Greeks the idea of the Corinthian order; the capitals being ornamented with a foliage very much resembling the Acanthus. Several animals painted on the ceiling have preserved their colours. To the south of Efné are seen the ruins of a monastery founded by St. Helena, and near it the burying place of the martyrs, adorned with tombs crowned by cupolas, supported by arcades. The inhabitants of Efné having revolted against the persecution of Dioclesian, this emperor destroyed the town, and put them to the sword. This place, consecrated by religion, is become a celebrated pilgrimage among the Copts, who repair hither from the most distant provinces of the kingdom. In the chain of mountains, which stretches to the eastward of the Nile, and nearly opposite to Efné, are quarries of a soft stone, called "Baram," which hardens in the fire, and is used in the manufacture of kitchen utensils. Savary's Letters, &c. vol. ii.

ESOCHE, from *εως*, within, and *εξ*, to have, in Surgery, a tubercle within the anus.

ESOPUS. See KINGSTON.

ESOTERIC. See EXOTERIC.

ESOX, in *Ichthyology*, a genus of the abdominal kind, distinguished by the following essential particulars. The head flattish above; mouth and throat large; jaws toothed, unequal, the upper one flat, lower punctated; tongue broad, loose; palate smooth; eyes round, moderate size, and lateral; nostrils double, near the eyes; gill-covers large, aperture ample, with from seven to twelve rays; body elongated, covered with hard scales; above convex, and compressed at the sides; lateral line straight, nearest the back, and scarcely visible; dorsal and anal fin very short, and generally placed opposite.

#### Species.

LUCIUS. Snout depressed; jaws nearly equal. Linn. *Fn. Suec. Art. Gen. Rondel. Brochet*, Bell. *Pike*, Penn. *Donov. Brit. Fishes*.

The pike is an inhabitant of most of the lakes of Europe, and the north of Asia, and also of many of the larger rivers in Lapland, Siberia, and countries adjacent. It grows to a considerable size, those of four or five feet in length not

being uncommon in the northern regions, and sometimes even they attain to the length of eight feet or more. The pike is highly prolific, and from its extreme voracity as well as cunning, is called the wolf, or the fox of fishes; it subsists on fishes, on frogs, serpents, and other reptiles, and on the young of swans and other aquatic fowl, and is reputed so undaunted in its attacks that it will even contend with the otter for its prey. This fish spawns in spring between the months of February and May. The colours vary in brightness at different seasons; in general the upper part is olivaceous green, with the back nearly black, and the whole spotted with yellow, whitish, or orange, according to the health of the fish. The belly white, and the fins beautifully variegated with vivid colours and spots of blackish purple. The jaws contain a formidable armament of teeth disposed in longitudinal rows. The longevity of the pike is well known to be very great; but what credit ought to be repoted in the assurances of some writers, that it lives to the age of two or three hundred years, must remain for others to determine. Their multiplication is immense; in the northern parts of Russia, and in Siberia, where they are taken in the greatest plenty, they constitute an article of commercial importance, being prepared by means of salting and drying, for exportation.

VIRIDIS. Green; lower jaw longer, scales thin. Gmel.

This is regarded by Bosc as a variety only of the common pike, (*Esox lucius*), the accuracy of which opinion appears rather uncertain, as we may perhaps be unacquainted with the species or fish intended by Gmelin; the reference of the latter author to the *Acus maxima squamosa viridis* for the same fish is supposed to be incorrect.

SPHYRÆNA. Dorsal fins two, the first spinous. Linn. *Arted. Sea pike or Spit-fish*, Charl.

There is some remote resemblance between this fish and the common pike, from which among other particulars it is distinguished by having the lower jaw advanced, the body more slender, the tail furcated, and the back furnished with two dorsal fins instead of one. The rays of the first dorsal fin are spinous, and are described both by Linnæus and Artedi as five in number, but according to Bloch these amount to only four. The fish is blueish above, beneath white; the pectoral, ventral, and anal fins red. It grows to the length of two feet, and inhabits the Atlantic and American seas. The flesh is in esteem.

The Barracuda pike of Shaw's *Gen. Zool.* described after Catesby, appears very closely allied to the preceding, if it be not the same; the character "brown, elongated, whitish beneath, with two dorsal fins and forked tail," differs from that fish only in having the upper part brown instead of blueish. It is found in the West Indies, and grows to the length of eight or ten feet.

BECCUNA. Silvery-blueish, marked on each side by a row of deep-blue spots, with two dorsal fins, and forked tail. Shaw. *Gen. Zool. Sphyræna beccuna*, Cope.

This accords so nearly with the *Esox sphyræna* that we cannot suppress our suspicions of its being the same. The only authority on which it is described is a drawing by Plumier; this, indeed, represents a fish of somewhat more elongated form, in which the sides are marked with a series of blue spots not observable in the former. If it prove distinct it is certainly very analogous. It is described as a native of the American seas.

AUREO-VIRIDIS. Body golden-green, with two dorsal fins, a spine before the first; lower jaw longer. *Sphyræna aureo-viridis*, Cope. *Gold-green pike*.

Described and figured by Cope from the drawings of Plumier; the body is deep, as in the sparus, the head sharp pointed;

pointed; scales middle sized; tail forked and lunated. The species inhabits the American seas.

**VULPES.** Dorsal fin in the middle of the back; the gill membrane three-rayed. Gmel. *Vulpes bahamensis*, Catesby. *Fox pike.*

Resembles the common pike, but is more slender in proportion towards the tail, the colour brown above, beneath paler. Native of Carolina and the West Indies.

**SYNODUS.** Dorsal fin in the middle of the back; gill membrane five-rayed. Gmel. *Synodus*, Catesby.

Closely allied to the former, and inhabits the same seas, and according to Cope the Mediterranean also. The body is marked with dusky bands; abdomen silvery; fins striped with black.

**HEPSETUS.** Lateral line silvery. Gmel. *Argentina pinna dorsali pinnae ani opposita*, Linn. Amœn. Acad. *Piquitinga*, Maregr. Inhabits America.

**MARGINATUS.** Dorsal and anal fins opposite; lateral line silvery; lower jaw six times as long as the upper. Forsk. Fr. Arab.

This and the preceding are supposed to be the same. The latter is described by Forskal as an inhabitant of the Red sea; its length about a span and a half; the body linear, tapering each side, and covered with broad lax, entire scales, the colour brown above, beneath white; the anal fin small, triangular, glaucous, and yellow without; dorsal yellow externally; tail bilobate, the upper lobe pale yellow, the posterior edge brown.

**CHINENSIS.** Head slender, lower jaw longer; eyes large and protuberant. *Sphyrana chinensis*, Cope.

Slightly described by Cope from the manuscripts of Commerçon as a native of the Indian seas. The general colour is said to be green with a silvery hue, and the scales of the middle size.

**CHILENSIS.** Jaws equal; lateral line blue. Molina. *Chili pike.*

Native of the Chilese seas. Length from two to three feet; body round, covered with bony angular deciduous scales, above golden, beneath silvery; flesh white, and excellent.

**ARGENTEUS.** Brown variegated with yellowish characters. Gmel. Forster, &c. *Silver pike.*

Inhabits fresh waters of New Zealand and other islands of the southern ocean.

**BRASILIENSIS.** Lower jaw very long; body serpentine. Linn. Mus. Ad. Fr.

These are several figures of this fish in different authors, most of which are defective in one particular or other. Nieuhoff omits the anal and ventral fins, Valentyn and Renard constitute two species of the same fish; and in other representations the dorsal fin is omitted. Linnæus erroneously refers to the Timucu of the Brasilians as being synonymous; the fish so named by these people has both the jaws elongated, and ending in a point, and is supposed to be the species Belone. Gmelin adopts the same misreference. The length of this fish is from twelve to fifteen inches; the upper part of the body green, beneath yellow, and the back marked with about six broad and equidistant bands of fuscous. The species inhabits the Brasils, and is esteemed a delicacy for the table.

**GYMNOCEPHALUS.** Jaws equal; gill-covers very obtuse; head naked. Linn. *Naked-headed pike.*

Native of India, according to Linnæus, who speaks of it as being the size of the sand lance.

**MALABARICUS.** Two canine teeth in each jaw; gill-membrane with five rays. Bloch.

Found in the rivers of Malabar. The length is about

twelve inches; its form somewhat resembling that of the common pike. The colour above greenish-blue, beneath yellow; fins yellow; at the base purplish, and marked with several distinct bands of brown. The lower jaw is rather longer than the upper, and the tail is rounded.

**CHIROCENTRUS.** Breast armed on each side by a spine over the ventral fin; lower jaw longer. Cope.

Described from the manuscripts of Commerçon. Its form resembles in some respects that of the common pike. The spine is said to be strong, and slightly curved; its length about two-thirds that of the fin, of which it appears to be the first ray.

**BELONE.** Each jaw long and subulate. Gmel. *Sea pike, gar-fish, or sea needle*, Penn. Donov. Brit. Fishes.

Length from eighteen inches to three or four feet, of a very slender eel like form, with long projecting snout, the back fine green; belly silvery. It is a common species in all the European seas; migrating annually in large shoals from the depths of the ocean to the shore. They appear on our coasts in the spring, commonly announcing the arrival of the mackerel, but remain with us for a much shorter period than that fish. They deposit their spawn close to the shore among the rocks and sea weeds, where the young are hatched, and after a certain time retire. We have seen the fry of this fish on our coasts during the summer months. As an article of food the gar-fish is held in far less estimation than the mackerel, to which its flavour in some degree approaches. By many people the flesh is considered unwholesome, and even poisonous; arising, no doubt, from the singular circumstance of the bone becoming of a fine grass green colour in boiling. This species grows to the length of eight feet. Donov. Brit. Fishes.

**SAURUS.** Jaws subulate, and slightly curving upwards, lower one longest; above and beneath spurious fins near to the tail. *Maxillis subulatis suascentibus, inferiore longiore, caudam versus supra infraque pinnulis spuris.* Donov. Brit. Fishes. *Saurus*, Rondel. *Skipper*, Ray. *The jaury*, Penn. &c.

The obscurity that prevailed respecting this curious fish till within a very recent period, induced us to enter on the details of its general description with rather more than ordinary minuteness: the writer of this article has already treated at some length on the *Esox saurus* in his work on British fishes lately published, and conceives a repetition of the following observations submitted on that occasion may net prove altogether unacceptable.

Our countryman Ray appears to be the first writer who describes this rare and curious species of esox as a native of Britain; he speaks of it as a Cornish fish, under the provincial name of skipper. Rondeletius and Gesner previously mention it as a scarce kind among the fishes of the Mediterranean. In 1769 the same fish was again introduced to notice by Mr. Pennant in his tour of Scotland, and afterwards in his British Zoology, wherein we are informed, that vast numbers of them were thrown ashore on the sands of Leith, near Edinburgh, after a great storm in November, 1778. In the summer of 1800 a single specimen was taken near the isle of Portland, in Dorsetshire, after a hard storm; an account of which, accompanied with a figure of the fish in its natural size, is given by the Rev. Mr. Rackett, in the third volume of the Linnæan Transactions. "This fish (Mr. Rackett observes) appears to be rare on the Dorset coast. Of the fishermen in this part, only one was acquainted with it, and called it a skipper, the name under which, according to Ray, it was known in his time on the coast of Cornwall. This writer adds that the species has not been noticed by Linnæus, Gmelin, nor Bloch; and that Pennant

nant has given a very indifferent figure of it in his *Tour in Scotland*, and has made use of the same plate in his *British Zoology*." See Linn. *Trans.* 3. p. 60.

It is altogether singular that this fish has no place in either edition of the *Linnæan Systema*, not even that by Gmelin; it is inserted by Dr. Turton in his translation on the authority of Pennant. The length of this species is about eighteen inches: the body of a long and slender form; not like that of an eel, as writers describe, but agreeing precisely with that of the common gar-fish (*Esox belone*). The snout is subulate, fine, toothless, and curving upwards. The jaws are of unequal length, the lower being longest, and bending upwards at the tip, in which respect it differs from the figures of Mr. Pennant and Mr. Rackett, in both which the jaws appear straight and of equal length. Neither do the jaws, when closed, exhibit that remarkable hiatus or gaping shewn in those two representations; there is a kind of flexuosity in the shape of the mouth, when open, which might excite such an idea, but upon gently closing it the curvature in the form of one jaw will be found to correspond with the figure of the other; so that the character "maxillis medio hiantibus," assigned to it, is by no means applicable. Dr. Shaw mentions in the *Gen. Zool.* that "in a specimen figured in the work of Cope, the jaws are represented upwards, contrary to what has hitherto been observed; the specimens figured in the work of Mr. Pennant, as well as that of Rondeletius, and the drawing by Mr. Rackett, have the jaws straight." This is certainly true, and it is therefore to be presumed that the examples from whence the figures of the latter mentioned writers have been taken must have sustained injury, or been misrepresented; for it is clear Cope is right in representing the jaws curving upwards: it is indeed evident, from the comparative shortness of the jaws in the figure by Pennant and others, they could not be perfect, the beak in the fish itself being nearly twice the length delineated by either. Dr. Shaw has also been apparently misled to the persuasion that the skin of this fish is reticulated by fine fins decussating each other at equal distances, which is not by any means the natural appearance of the fish, and the figure in the *British Zoology* is still more erroneous, as it appears entirely smooth, and destitute of scales.

Some misunderstanding seems to prevail likewise as to the colour of the fish. Mr. Pennant describes it as having the back dusky, and the belly bright and silvery, in which particulars he is followed by Dr. Shaw, who remarks that the colour of the whole animal is dusky above, and silvery beneath, with dusky or blueish brown back. This is not, however, correct, the true colour of the back of the fish is a most lovely azure blue, changeable to green, and glossed with purple and yellow, and the lower parts silvery. The body has a smooth appearance, the scales with which it is covered being thin and glabrous: the lower part of the body from the gills to the tail is marked with a longitudinal carina or keel, which terminates at the latter part in a somewhat protuberant manner.

The species may be readily distinguished by the pinnules or spurious fins on the body near the tail, in which particular it agrees with the scomber or mackerel genus; these have been variously misrepresented; in the fish itself they amount altogether to twelve in number, five of which are disposed above and seven beneath; and it is also necessary to add that they are perfectly detached from each other. The fish, in point of flavour, resembles that of the mackerel.

*CASSEUS*. Upper jaw longer; scales bony. Linn. *Esox maxilla superiore cauda quadrata*, Arted.

Native of North America and Asia, and has been found

in Europe. (Donov. *Brit. Fishes*.) The species is from two to three feet in length, and is covered with rhombic scales.

*CEPEDIANUS*. Snout long, jaws spatulate; scales bony. *Le pisosteus spatula*, Cope. *Esox cepedianus*, Shaw.

The principal difference between the two last mentioned fishes seems to consist in the snout being shorter in proportion in *E. cepedianus* than the other. There is likewise another pike of the same bony scale kind, which has the jaws rather shorter than either, and bears the name of *Leve-rianus*. We are not entirely satisfied that the three last mentioned differ specifically from each other.

No small degree of uncertainty seems to prevail throughout this tribe of fishes independently of those last adverted to; the species *synodus*, *hepsetus*, *vulpes*, and *marginatus*, appear to be imperfectly understood: *barracuda*, *viridis*, and *becuna*, are perhaps more doubtful, as are also *chiro-centrus*, and *chiensis*; and it will have been observed that the true characters of the species *saurus* were not till lately ascertained.

The viper-mouthed pike (*Esox stomias*), and *vipera marina* of Catesby, is distinguished by having four of the teeth much larger than the rest: this is a very extraordinary fish, and ought, in our opinion, to constitute a new genus.

*ESPADACINTA*, in *Geography*, a town of Portugal, in the province of *Tras-los-Montes*, situated on the *Duero*, and borders of Spain; 34 miles S.W. of *Miranda de Duero*, and 28 N. of *Almeida*.

*ESPAGNAC*, JOHN-BAPTIST-JOSEPH DE SAHUGUET-DAMARZIL, BARON D', in *Biography*, a military writer, was born in the year 1713 at *Brive-la-Gaillarde*. At the age of nineteen he entered the army, and became celebrated for great skill and prowess. In 1742 he was aid-de-camp in the war of *Bavaria*, and was afterwards employed by *Marshal Saxe* as aid-major general and colonel of a regiment of grenadiers. In 1780 he was raised to the rank of lieutenant-general, and died at *Paris* in 1783. As an author he attained a good share of celebrity by his "Campaigns of the King in 1745-48," which were published in four octavo volumes. He published also "Essays on the Science of War," 3 vols. 8vo. "An Essay on the great Operations in War," in 4 vols. 8vo; "A Supplement to the Reveries of *Marshal Saxe*," in 2 vols. 8vo. 1773. He likewise drew up "The History of *Marshal Saxe*," in 3 vols. 4to. in which are detailed plans of his battles and marches, together with those particulars of the life of that general, as render it a work of considerable interest to literary as well as to military men." *Nouv. Dict. Hist.*

*ESPAGNAC*, in *Geography*, a small town of France, in the department of the *Lozere*; 12 miles S. of *Mende*.

*ESPAGNE*, JOHN D', in *Biography*, a French protestant divine in the seventeenth century, was born at *Dauphiné*, and became minister of the French church in *London*, an office which he sustained during the reigns of *James I.* and *Charles I.* He published several small tracts, which were afterwards collected and published at *Geneva* and the *Hague*, in three and in two volumes 12mo. about the year 1670. He also published a work, which he dedicated to *Charles I.*, entitled "Erreurs Populaires en points Généraux qui concernent l'Intelligence de la Religion." Of this and of some other of his pieces *Bayle* speaks in terms of commendation. *Moreri*. *Bayle*.

*ESPAGNE*, in *Geography*. See *EPAIGNE*.

*ESPAGNET*, JOHN D', in *Biography*, who flourished in the 17th century, was president of the parliament of *Bourdeaux*. As a literary character he published a work entitled "Enchiridion Physicæ Restitutæ," which was afterwards

wards translated into French under the title of "La Philosophie des Anciens retablie en sa Pureté." This may be regarded as the first book that appeared in France, in which there is a complete system of physics contrary to that of Aristotle; though the author pretended that he had merely re-established the ancient philosophy. He published also a work concerning the philosopher's stone, entitled "Arcanum Hermeticae Philosophiæ Opus." Also an old MS. entitled "Le Rozier des Guerres," found at Nerac in the king's closet, and attributed, though erroneously, to the pen of Lewis XI. To this work he added a treatise of his own, upon the education of a prince. In publishing the "Rozier des Guerres," he followed the original with the utmost exactness, because, says he, "this little tract seemed to me so good, that I would not embellish or disguise it, but have left it in its native simplicity: and though the language of it is not in use in this age, yet it may be understood, being so full of good sense and meaning, that with all its jargon it may silence the affected language of the court and bar. I have also carefully preserved the spelling, because in adding or diminishing a letter, a word is often changed, and of old made new." Bayle.

ESPAIN, SAINT, in *Geography*, a small town of France, in the department of Indre and Loire; 15 miles S.E. of Chinon.

ESPALIER TREES, in *Gardening*, are such fruit trees of low growth as are trained to treillages or framed wood-works made for the purpose, in ranges, so as to constitute a sort of hedge. They are usually planted in single rows along the borders, on the sides of the principal walks, in the main divisions of the garden, affording shelter to other plants as well as ornament to such parts.

The sorts of fruit trees mostly employed in this way are those of the apple, pear, and plum kinds; but many others may be managed in this method where variety is wanted; as the quince, cherry, almond, apricot, mulberry, and filbert. And it is necessary, with a view to beauty and uniformity, to manage them in such a manner as to have them that are nearly of the same growth in the same range or line of planting.

The sorts of apples most adapted to this use are those of the golden and other pippin kinds, the nonpareil, rennet, and russet; but many others may be cultivated in this way.

In the pear-kind, the jargonelle, blanquette, bergamot, burre du Roy, &c: the melting pears being always better in this way than those of the breaking kind. On strong moist soils those grafted on quince stocks are the best, but on dry ones those on free stocks.

Trees intended for this use should be grafted or budded within a few inches of the surface of the ground, that branches may be thrown out regularly from the bottom upwards, to furnish and fill the treillage; and the more effectually to accomplish the purpose, the first shoots from the grafts, &c. should be cut off, or headed down within a few inches of the grafts, in the spring season, when they have had one year's growth. The branches or shoots thus produced, whether the trees are in the nursery, or planted out as espaliers, should, in the latter part of the summer, or beginning of autumn, be trained both ways laterally in their advancing growth, to stakes put down for the purpose, or the espalier frames. In this way the trees acquire a proper form, those in the nursery being thus trained and kept for sale. A second heading down in the upper branches may likewise be practised when necessary, in order to fill up the middle, and completely cover the frames.

When these trees have been thus trained for three or four years in the nursery-ground, they are generally in a

proper situation for being planted out as espaliers in the borders or other parts along the sides of the walks in the garden or pleasure ground, a sufficient breadth being allowed for the borders according to the size or extent of such grounds, as six, eight, ten, or more feet.

Besides this, there is another method sometimes practised in forming espalier trees, which is that of, after heading the first shoots down as above, training the side-shoots horizontally in the direction of the frames, and the middle one upright, forming the lateral shoots, which it throws out horizontally on each side; and, if they are not thrown off sufficiently low, heading the upright one down, by which lateral branches will be sent off, so as to range with regularity at the distance of six or seven inches, one above another, on each side, from the bottom to the top. In this way the trees have a very neat appearance.

In planting the trees out, when they are of the apple or pear kind, on dwarf stocks, the distance in the rows should be fifteen, eighteen, or twenty feet; and when on free stocks, not less than twenty or thirty; and for free growing trees considerably more. For plums, the distance should be eighteen feet or more; and for cherries, apricots, almonds, and mulberries, it should never be less than fifteen. Considerably less distance will, however, be sufficient for filberts, especially in the poorer sorts of soil.

When these trees have been planted, it is the usual practice to put sticks down in a line to train them to for the two or three first years; but it has a much neater appearance to have the treillage fixed down to train them to at once.

Frames for this use are made in different ways, according to the taste of the person who has them; but the most usual sorts are those constructed of three or four inch square pieces of oak timber for the posts, with rails of deal carried from post to post, at the distance of every ten or twelve inches from the bottom to the top. Between these rails thin upright pieces are again sometimes fixed at the same distances, for particular purposes. The whole should be well painted over in oil some time before the trees are to be trained to it. This last is performed either by tying the branches to the trellis by osier twigs, woollen-yarn, or other similar substances, or by nailing them in the manner of wall-trees. In whichever way it is done, the greatest exactness and regularity should be observed in laying in and directing the shoots, that they may have a neat regular appearance. The manner of performing the future pruning and managing of these trees will be explained when we come to speak of the nature of pruning in general. See PRUNING of Fruit Trees.

These sorts of trees are chiefly advantageous in admitting the branches to produce fruit spurs on both sides, which is not the case with wall-trees; in taking up but little room in the garden; in not being so injurious to the crops that are near them; in affording fruit of a finer flavour, from the more free admission of air and sun, and in the fruit not being so liable to be blown down and injured as in other cases.

ESPALION, in *Geography*, a small town of France, in the department of the Aveyron, chief place of a district of the same name, with a population of 2622 inhabitants. It is situated on the river Lot, 18 miles N.E. of Rhodéz, and has some manufactures of coarse woollen cloth. The canton has a territorial extent of 167½ kilometres, 12 communes, and a population of 9139 individuals.

As chief place of a district, Espalion has a sub-prefect, a court of justice, and a register office. Corn, wine, and madders, grow in its neighbourhood, and the whole district contains 9 cantons, 101 communes, and 58,855 inhabitants, on a territorial extent of 1630 kilometres.

ESPAMISCACK, a lake of Lower Canada; 74 leagues N.E. of Quebec. N. lat 50°. W. long. 68°.

ESPAQUE, a town of Persia, in the province of Segeftan; 54 miles S.W. of Kin.

ESPARCET, in *Agriculture*, a name sometimes given to faintfoin. See SAINTFOIN.

ESPARRAGOSA, in *Geography*, a town of Spain, in the province of Estremadura; 35 miles E.S.E. of Merida.

ESPARRAGUERA, a town of Spain, in the province of Catalonia; 15 miles N.N.W. of Barcelona.

ESPARZA, a town of Spain, in Navarre; 22 miles E. of Pamplona.—Also, a town of North America, in Mexico, and province of Costa-Rica.

ESPEJA, a town of Spain, in the province of Cordova; 17 miles N.N.E. of Montilla.

ESPELETTE, a small town of France, in the department of the Lower Pyrenées, chief place of a canton in the district of Bayonne, with a population of 1200 individuals. Its canton has a territorial extent of 237½ kilometres, 7 communes, and 7861 inhabitants.

ESPEN, ZEGER BERNARD VAN, in *Biography*, was born at Louvain in the year 1646. After going through the usual course of studies at the university, with much credit to his talents and diligence, he was admitted to priest's orders in the year 1678, and had, within two years of this time, the degree of doctor of laws conferred upon him. From this period till the year 1702, he lived in the college of pope Adrian VI., where he performed the duties of professor, and applied himself to the study of those works which have rendered his name illustrious. He obtained so much respect by his various writings that he was consulted from every quarter: by the tribunals of justice, by the bishops, and by several sovereign princes. His principal work was entitled "Jus Ecclesiasticum Universum." Besides this, he is well known for other treatises, "De peculiaritate et Simonia;" "De Officiis Canonicorum;" "Tractatus Historico-Canonicus in Canones;" "De promulgatione Legum Ecclesiasticarum," and many others, all of which were collected and published in 4 vols. folio, in 1753, at Paris. When he was in his 65th year, he was deprived of sight by a cataract, which was not removed for two years; during this time, however, he neither lost his cheerfulness, nor remitted his application. His manner of living was at all times frugal, and very simple, his temper was benevolent, modest, and humble. He was eminent for piety towards God, and for his candour and good-will towards men. He nevertheless had made himself enemies, by the integrity and independence of his mind; some of whom, to render Espen obnoxious to the ruling powers, had forged a treatise, containing some things very offensive, in a religious and political point of view, which they attributed to him; but he luckily detected the imposture, and punished the agents. On other accounts, he met with severe and unmerited persecution, and in one instance, after a variety of processes, sentence was pronounced against him, without any declaration respecting the definitive judgment of the court. Under these circumstances, believing that it was intended to put him under an arrest, he withdrew to Maestricht, and afterwards to Amersfort, in the province of Utrecht, where he died in 1728, in the 83d year of his age. He left behind him, which was afterwards published, a learned treatise, entitled "Commentarius in Canones Juris Veteris ac Novi," and other dissertations, which are said to contain discussions on some of the most important points in moral philosophy, as well as the canon and civil laws. Moreri.

ESPENCE, CLAUDE DE, was born at Chalons sur Marne in the year 1511. He received his education at

different colleges in Paris, to the principal of which he was chosen rector at a very early age. When he was about thirty years old, he took his doctor's degree, soon after which he was invited by the cardinal of Lorraine to reside in his house, to manage the ecclesiastical concerns of which he had the care. In the year 1544 he accompanied the cardinal on an embassy to Flanders, to negotiate a treaty of peace between Francis I. and the emperor Charles V. He was afterwards selected by the king to assist at the ecclesiastical conference, to consider the questions proper to be proposed for discussion at the council of Trent; and in 1547 he was deputed by Henry II. to attend the council of Trent, which was then transferred to Bologne. Some years afterwards he was employed in negotiating at Rome in favour of the French court, where his talents, as a diplomatic minister, produced such an impression in his favour, that the pope, Paul IV. wished to attach him to his interests by making him cardinal. He declined the intended honour, and having finished the business on which he was sent to Rome, he returned to his native country, where he appeared with high reputation at a meeting of the States at Orleans in the year 1560. In the following year he was appointed a member of the conference at Poissy, where he attached himself to the Calvinists, which was highly disagreeable to the Catholic divines, by whom he was likewise suspected of being the author of a treatise on Image Worship, which occasioned him some trouble with the faculty. After this, he passed his life in retirement, devoted to his studies, till he died at Paris in the year 1571. His works are chiefly theological; the most important are his "Commentaries on the Epistles of St. Paul to Timothy and Titus;" in these, several questions relative to hierarchy and ecclesiastical discipline are discussed. Most of his treatises were written in the Latin language, in the knowledge of which he was supposed to excel his contemporaries. He was one of the most learned, judicious, and moderate ecclesiastics of his time. He was very conversant in the canons and discipline of the church; and not less celebrated for his knowledge of profane literature. He was attached to the Catholic religion, but was a decided enemy to every species of persecution and intolerance. Moreri.

ESPER, JOHN FREDERIC, was born at Drossenfeld, in Bayreuth, in 1732. He studied very diligently at Erlangen, where he applied himself chiefly to theological pursuits, but at the same time made himself well acquainted with natural history and botany, of which he afterwards became a teacher. He died of a fever in July 1781, leaving behind him a considerable reputation as a naturalist, particularly in that department which relates to the zoolites in the principality of Bayreuth. In this place are a number of large subterranean caverns, partly insulated, and partly connected with each other, which contain immense numbers of bones of various animals, thrown together in heaps to a considerable height, and covered with the earth arising from decomposed animal bodies. The entrance to these caverns is highly picturesque, but almost as soon as a person enters them he is surrounded by darkness, and the passage becomes still more difficult and narrow, till the eye at last is struck by the immense extent of an awful arch, which on every side presents fissures and clefts, strewed with the fragments of once living bodies, which excite the idea of a repository of the dead. With the aid of an ingenious apothecary of Erlangen, Esper undertook an examination and description of these curiosities, and published the result of his labours under the following title; "An accurate Description of the Zoolites of Unknown Animals, &c." This was published at Nuremberg, in the year 1774, in folio, with

fourteen illuminated plates. Esper was author likewise of various papers in the Transactions of the Friendly Society of the Searchers into Nature: and he wrote an account of "A Method of determining the Orbits of Comets, and other Celestial Bodies without Instruments, or Mathematical Calculations." Gen. Biog.

ESPERAZA, in *Geography*, a town of France, in the department of the Aude, and district of Quillan;  $2\frac{1}{2}$  leagues S. of Limoux.

ESPERNAY. See *EPERNAY*.

ESPERNON, a small town of France, in the department of Eure and Loire, on the river Guesle; 15 miles N.E. of Chartres, and 6 miles E. of Maintenon.

ESPESEL, a town of France, in the department of the Aude, and district of Quillan;  $2\frac{1}{2}$  leagues S.W. of Quillan.

ESPHLASIS, (from *εσφρασις*, to recede inwards,) in *Surgery*, a recession of a part of the body inwards, in consequence of some violent outward force.

ESPIERRE, a town of Savoy, in the county of Maurienne, on the river Arc;  $3\frac{1}{2}$  miles S. of Argentina.

ESPIERS, in *Geography*, a town of Flanders; 5 miles N. of Tournay.

ESPINAL. See *EPINAL*.

ESPINAR, a town of Spain, in Old Castile; 18 miles S.S.W. of Segovia.

ESPINHAL, a town of Portugal, in the province of Beira; 18 miles S.E. of Coimbra.

ESPINOSA DE LOS MONTEROS, a small town of Spain, in Old Castile; situated in a pleasant valley, watered by the river Trueya, among the mountains of Burgos, about 15 leagues N.W. of Miranda, in the north corner of the province.

ESPINOSA, a town of Spain, in New Castile; 44 miles S.W. of Toledo.

ESPIRITU SANTO, the largest and most westerly of the New Hebrides islands, in the South Pacific ocean, about 57 miles in length, and 30 in breadth.—Also, a province of Brasil, which is chiefly productive of sugar.—Also, a town of Brasil, seated in a fertile country on the sea-coast, with a small castle and harbour. S. lat.  $20^{\circ} 10'$ . W. long.  $41^{\circ}$ .—Also, a river of Brasil, which runs into the Atlantic.—Also, a town on the south coast of the island of Cuba; 55 miles S.W. of Bayamo.—Also, a bay on the west coast of East Florida. N. lat.  $27^{\circ} 36'$ . W. long.  $82^{\circ} 54'$ . It has a good harbour and safe anchorage; but the land about the sea-coast is very low. Several low, sandy islands and marshes, covered with Mangrove bushes, lie before the main land. This bay abounds in the summer with fish, which may be taken with a seine, in quantity sufficient to load a ship, if the climate would admit of curing them, in a few days.—Also, a lake towards the extremity of the peninsula of East Florida, south from the chain of lakes which communicate with St. John's river.

ESPIRITU Santo, *Ilas del*, islands situated on the S. W. of Providence in the West Indies. See *ANDROS islands*.

ESPLANADE, in *Fortification*, called also the glacis; a part which serves the counterscarp, or covert way, for a parapet; being a declivity, or slope of earth, commencing from the top of the counterscarp, and losing itself, insensibly, in the level of the campagne.

ESPLANADE also signifies the ground which has been levelled from the glacis of the counterscarp to the first houses; or the vacant space between the works and the houses of the town.

The term is also applied, in the general, to any piece of

ground which is rendered flat, or level; and which before had some eminence that incommoded the place.

ESPLEES, *EXPLETIE*, from *expleo*, in *Law*, the products which ground or land, &c. yield; as the hay of the meadows, the herbage of the pasture, corn of the arable, rents, services, &c. and of an advowson, the taking of tithes in gross by the parson; of wood, the felling of wood; of an orchard, the fruit growing there; of a mill, the taking of toll, &c. These and such like issues are termed esplees. And it is observed, that in a writ of right of land, advowson, &c. the demandant ought to allege in his count, that he or his ancestors took the esplees of the thing in demand; otherwise the pleading will not be good.

Sometimes this word hath been applied to the farm, or land, &c. themselves. "Donnaus E. habebit omnia expletias & proficua de corona emergentia." Plac. Parl. 30 Ed. I.

ESPOSENDA, in *Geography*, a town of Spain, in the province of Galicia; 12 miles S.W. of Orense.

ESPOSENDE, a small port town of Portugal, in the province of Entre Mimbo, at the mouth of the Cavado, three leagues S. of Viana. Its shallow harbour is slightly protected by a fort, 22 miles N. of Oporto.

ESPRIT, JAMES, in *Biography*, was born at Besiers in the year 1611. Having passed through his initiatory studies, to which he had applied himself with great diligence, he was introduced to the duke de la Rochefoucault, who brought him acquainted with the chancellor Seguier, who not only allowed him a pension from his own private purse, but procured for him a pension of two thousand livres, on an abbey and a brevet of counsellor of state. Through some secret enemies he incurred the displeasure of the chancellor, and withdrew to the seminary of St. Magloire, where he became acquainted with the prince of Conti, and at that time had serious thoughts of entering the church. This prince was so charmed with the conversation of M. Esprit, that he gave him handsome apartments in his own hotel, and a pension of a thousand crowns. In a short time afterwards Esprit gave up all thoughts of the ecclesiastical life, and determined to marry. On this occasion he received some handsome presents from the prince, to whom he became so much attached that he followed him, in 1766, to his government of Languedoc, and became his most confidential friend and adviser. After the death of his patron, he devoted the whole of his time to the education of that prince's children. He himself died at the place where he was born in 1678. As a literary man he left behind him "Paraphrases on some of the *Palms*;" and a treatise, entitled "La Fausseté des Vertus humaines," in two volumes, which was published the same year in which he died, and which was intended as a commentary on the maxims of his first patron the duke de la Rochefoucault, to show the fallacy of the virtues that are merely human, and the reality of Christian virtues. By the abbé Olivier and others he is supposed to have been the translator of Pliny's panegyric on Trajan. Esprit was a member of the French academy, and in its infancy was considered as one of its shining ornaments. Moreri.

ESPRIT, *Saint*, in *Geography*, a small town of France, in the department of the Landes, chief place of a canton in the district of Dax, with only 589 inhabitants. Its canton has a population of 10,161 individuals, dispersed in eight communes, on a territorial extent of  $147\frac{1}{2}$  kilometres.

ESPOUSALS, *SPONSALIA*, in *Law*, a contract or mutual promise between a man and a woman to marry each other. Marriage or matrimony is said to be an espousal or presenti.

ESPRONCEDA, in *Geography*, a town of Spain, in Navarre; 11 miles W.S.W. of Estella.

ESQUADRILLE. See QUADRILLE.

ESQUADRON. See SQUADRON.

ESQUERDES, in *Geography*, a town of France, in the department of the straits of Calais, and district of St. Omer; one league S. of St. Omer.

ESQUIAVINE, in the *Manege*, an old French word signifying a long and severe chastisement of a horse in training him.

ESQUILLÆ, or ESQUILINUS MONS; in *Ancient Geography*, one of the seven mountains on which Rome was seated, where was anciently one of the gates of the city, now the gate of St. Laurence, to whose magnificent church it leads. This gate seems to have been anciently called "Libitincensis," on account of the dead bodies that were carried through it, in order to their being interred in the "Campus Esquilinus," which was the general burying-place of the common people. The name of Esquilinus was varied, for facility of pronunciation, from Exquilinus, a corruption of Excubinus, *ab Excubiis*, from the watch that Romulus kept in this place. It was taken in by Servius Tullius, who had his royal seat upon this hill. Varro will have the Esquilæ to be two hills. To the east, it has the city walls; to the south, the via Labicana; to the west, the valley lying between Mons Cælius and Mons Palatinus; to the north, Mons Viminalis; and is in compass between three and four miles. It is now called "Il Montè de Santa Maria Maggiore." One of the 14 regions or wards, instituted by Augustus, was denominated "Esquilina." It contained 15 streets, eight luci, six temples, five ædes, 75 public baths, 18 granaries, 22 mills, and 180 great houses; and its circuit was 15,950 feet.

ESQUIMAUX, the inhabitants of the coasts of Labrador and Hudson's bay, who differ, in several characteristic marks, from the inland inhabitants of North America. That the Greenlanders and the Esquimaux agree in every circumstance of customs, and manners, and language, which are demonstrations of an original identity of nation, was discovered near half a century ago. Crantz, in his "History of Greenland," (vol. i. p. 262.) informs us, that the Moravian brethren, who, with the consent and furtherance of sir Hugh Palliser, then governor of Newfoundland, visited the Esquimaux, or the Labrador coast, found that their language, and that of the Greenlanders, do not differ so much as that of the high and low Dutch. Mr. Hearne, in 1772, traced this unhappy race farther back, towards that part of the globe, from whence they had originally exalted along in their skin-boats, having met with some of them at the mouth of the Copper-mine river, in the latitude of 72°, and near 500 leagues farther west than Pickersgill's most westerly station in Davis's strait. Their being the same tribe, who now actually inhabit the islands and coasts on the west side of North America, opposite to Kamtschatka, is a discovery, the completion of which was reserved for captain Cook. The reader of his third voyage will find them at Norton sound, and at Oonaleska, and Prince William's sound; that is, near 1500 leagues distant from their stations in Greenland, and on the Labrador coast. And lest similitude of manners should be thought to deceive us, a table exhibiting proofs of affinity of language, drawn up by captain Cook and inserted in the appendix to the work just cited, will remove every doubt from the mind of the most scrupulous inquirer after truth. See *NEW BRITAIN* and *LABRADOR*.

ESQUIMAUX Bay. See *ESKIMAUX*.

ESQUINANCY, in *Medicine*, from the French *esqui-*

*nancie*; whence our more common term *quinsy*. See *CYNANCHE*.

ESQUIRE, a title of distinction, next below that of knight, and above that of a simple gentleman.

The origin, both of the name, and the thing, esquire, is very obscure. The English denomination is confessedly borrowed from the French, *escuyer*; and that from the Latin *scutum*, shield, as some will have it; or, as others, from *scutarius*, or *scutiger*, shield-bearer; or from *scuria*, stable; or from *equiso*, groom. So many different opinions of the formation of the word have given rise to as many about the primitive office of esquires; unless, perhaps, the latter hath given occasion to the former. Pasquier, in his *Recherches*, liv. ii. chap. 15. maintains the title of esquire, *escuyer*, *scutarius*, to be very ancient. From the time of the declension of the Roman empire, he observes, there were two extraordinary kinds of soldiery in the Roman army: the one called *gentiles*, and the other *scutarii*.

Ammian. Marcellin. lib. xiv. cap. 7. and lib. xvi. cap. 4. speaks of these *scutarii* as men of redoubted prowess, and even deemed invincible: it is added, that Julian the Apostate set a mighty value on those troops, when he was among the Gauls; and hence, probably, it was, that the Gauls, or perhaps only the Franks, finding the bravest among the Roman forces were called *gentiles*, and *scutarii*, gave the like names to the boldest and bravest among themselves; such, according to that curious antiquary, is the original of esquires.

Esquire, however, afterwards came to be used in a somewhat different sense; *viz.* for a gentleman who attended a knight in the wars, and on other military occasions; bearing his shield, *scutum*, before him (whence he was called *scutarius*, *scutiger*, or *scutifer*), as also his lance, and other weapons; whence his other Latin appellation, usual among us, *armiger*, *q. d. armour-bearer*. And hence likewise it is, that, in all our ancient romances, the hero is constantly attended by a gentle and truly *Esquire*.

After all, the most probable derivation of *escuyer* is not from *escu*, *scutum*, as is the common opinion; but from *equus*, horse; the primitive esquires being no other than what the Latins call *equisons*, who had the care and intendance of the equerries, or stables, only.

Be this as it will, the title *esquire*, *armiger*, as now established among us, is next below that of knight, *equus*. They who bear this title are all younger sons of noblemen, and the eldest sons of such younger sons; the eldest sons of knights, and their eldest sons successively; both which species of esquires sir Henry Spelman entitles *armigeri natalitii*; the four esquires of the king's body, now difused, and esquires created by the king, by putting about their necks a collar of SS's, and bestowing on them a pair of silver spurs, letters patent, or other investiture, and their eldest sons. Lastly, divers others, in the superior public offices, are reputed esquires, or equal to esquires; as sheriffs of counties, serjeants at law, justices of peace, mayors of towns, counsellors at law, lieutenant-colonels, majors, captains, &c. during the time of their commission. Lastly, the heads of some ancient families are likewise esquires by prescription. To these may be added the esquires of knights of the Bath, each of whom constitutes three at his installation; and all foreign, nay Irish peers; for not only these, but the eldest sons of peers of Great Britain, though frequently titular lords, are only esquires by the law, and must be so named in all legal proceedings. See *GENTLEMAN*.

ESQUISSE, in the French *Painting*, a term signifying the first slight sketch or draught of a picture; the first thought

thought of a design drawn hastily with a crayon; or in colours, on paper, canvas, or the like, in order to be finished, and painted, or engraven afterwards.

He had not the trouble of making a finished and correct design, but went to work upon the esquisse.

The word is formed of the Italian *schizzo*, a splash; because an esquisse of a painting only represents, as it were, splashes, or dabs, of colours.

ESQUIVO. See ESSEQUIVO.

ESRAKITES. See ESCHRAKITES.

ESS, in *Agriculture*, a term made use of in some places to signify ashes.

ESSA, in *Ancient Geography*, a town of Palestine, on the other side of Jordan, according to Josephus, who says that it was taken by Alexander, king of the Jews.

ESSACHORDO. See HEXACHORD.

ESSÆANS. See ESSENI.

ESSAORE, in *Geography*, a town of Egypt; three miles S.S.E. of Achmin.

ESSARS, LES, a town of France, in the department of La Vendée, and district of La Roche-sur-Yon; 3 leagues N.E. of La Roche.

ESSART, of ASSART. See ASSART.

Du-Cange derives the word from some of the barbarous Latin words, *exartus*, *exartum*, *essartum*, *assartum*, *fartum*, and *fartus*; which all signify a forest cut down, or dug up; though Spelman chooses to deduce it from the Latin *exertum*, torn up, or unrooted. Others from *farrine*, to weed; and others, lastly, from *exaro*, I plow; whence *exarare*; and, by contraction, *exartum*. In our ancient law-books, "exartum facere in sylva," is to essart a place in a forest. To essart, is to grub up, or extirpate bushes, trees, old roots, stumps, or the like; in order to fit the ground for tillage.

ESSARTS, LES, in *Geography*, a small town of France, in the department of La Vendée, chief place of a canton in the district of Montaigne, with a population of 2089 individuals, 24 miles W. of Mauléon. Its canton contains 9 communes, and 9043 inhabitants, on a territorial extent of 242½ kilometres.

ESSATUM, a word used by some of the chemical writers to express the medicinal power or sanative property residing in simple medicines.

ESSAY, a trial, or experiment, to prove whether a thing be of the requisite quality or goodness.

The word is French, *essai*; which some authors derive farther from the Latin *examen*.

ESSAY is also used for an attempt, or tentative, to learn whether or not a thing will succeed.

Essays of machines should be made in large; it is not enough that they succeed in little.

ESSAY, in *Monasteries*, is particularly used for a trial which a person makes of the monastic life, in a secular habit.

This essay is of one, two, and, in some monasteries, of three months. The essay is not reckoned in the noviciate. See PROBATION.

ESSAY, or *Assay*, or simply *Say*, in *Coinage*. See ASSAY.

ESSAY, in matters of learning, is a peculiar kind of composition; whose character is to be free, easy, and natural; not tied to strict order, or method, nor worked up, and finished like a formal system.

The matter of an essay is supposed to consist principally of sudden and occasional reflections, which are to be wrote much at the rate, and in the manner, a man thinks; some-

times leaving the subject, and then returning again, as the thoughts happen to arise in the mind.

At least, this has hitherto been the practice; and Montaigne, who has acquired no small reputation by this way of writing, seldom keeps many lines to the subject he proposes; though it is our opinion, that lord Bacon, in many of his works, is a better pattern in the essay kind. Mr. Locke, however, and a few other authors, use essay in a stricter sense: the Essay of Human Understanding, every body knows, is a regular, artful, and laboured work; though perhaps so called to guard against too severe strictures, by pleading the title.

ESSAY-hatch, is the miners term for a little trench or hole, which they dig to search for shoad; or ore. See TIN.

ESSAY-master. See MINT, and ASSAY.

ESSE, in the *School Philosophy*, is used in the same sense with essence; principally for that which is actual, or actually existing.

The word is pure Latin; being the infinitive of the verb *sum*, I am; whence *esse*, to be.

From esse arises *essatum*, a barbarous term, now almost obsolete, signifying that which is ended with essence, or nature; or affected with the virtue, or efficacy, of another. Some distinguish esse into *real* and *intentional*; and, again, into *essatum* and *volitum*.

ESSEDARIUS, among the Romans, a gladiator, who fought in a car or chariot. See Hist. Acad. Inscrip. vol. ii. p. 376. seq.

ESSEL, or EBSTEL, in *Geography*, a town of Germany, in the circle of Westphalia, and county of Verden; 2 miles N. of Verden.

ESSEN, a small town of Germany, in the circle of Westphalia, remarkable for its manufactures, chiefly of swords and fire arms; but more particularly for a rich abbey, which, until the peace of Luneville in 1801, was a free imperial abbey. It was secularized, and its possessions, together with the town and its territory, were given to Prussia as an indemnity for her losses on the right shore of the Rhine. After the peace of Tilsit in 1807, when Prussia lost all her dominions beyond the Elbe, Essen was added to the grand duchy of Berg and Cleves, which now belongs to the eldest son of the king of Holland. There are other towns of this name in the circle of Westphalia.

ESSENBACK, a town of Denmark, in Jutland; 4 miles from Randers.

ESSENBERG, a town of Germany, in the circle of Westphalia, and county of Meurs, near the Rhine; 3 miles E. of Meurs.

ESSENCE, a term much used among the schoolmen; and denoting what the Platonists called the idea of a species. The word *essentia* is said to have been made by Cicero; but his authority could not give it currency, until long after his time. It came at last to be used, and the schoolmen fell into much the same opinions concerning essences, as the Platonists held concerning ideas. The essences of things were held by many to be uncreated, eternal, and immutable. Mr. Locke distinguishes two kinds of essence, the real and the nominal. By the former he means the constitution of an individual, which makes it to be what it is. This essence must begin and end with the individual to which it belongs. It is not therefore a Platonic idea. But the latter or nominal essence, so called by Mr. Locke, is the constitution of a species, or that which makes an individual to be of such a species; and this is nothing but that combination of attributes which is signified by the name of the species, and which we conceive without regard to existence. The essence of a species is, therefore, what

what the Platonists called the idea of the species. The nominal essence depends on the real essence; thus, the nominal essence of gold, is that complex idea which the word gold represents; *e. gr.* a body, yellow, heavy, malleable, fusible, and fixed; but its real essence is the constitution of its insensible parts, on which those qualities, and all its other properties depend; which is wholly unknown to us.

In philosophy, the essence of a thing is defined to be, that whereby a thing is distinguished from every other thing. The Cartesians hold the essence of matter to consist in extension; and, on that principle, deny that there is any such thing as mere space, or vacuity; but the hypothesis is false, as will be shewn under the articles MATTER, SPACE, VACUITY, PLENUM, &c.

Gassendus, and most of the corpuscular philosophers, hold the essence of matter to consist in solidity, or impenetrability, resistance, or, more adequately, in a solid impenetrability resisting the touch; which it must be allowed, of all the properties of matter, seems to have the fairest title to it.

The school philosophers give us two significations of the word essence; the first denotes the whole essential perfection of a being, and, consequently, its entity, with all its intrinsic, or essential, and necessary attributes, taken together; in which sense, essence may be defined to be, all that whereby a thing is, and what it is. In which case the essence of a thing is to the thing itself, what humanity, *e. gr.* is to man.

The second signification of essence is; that whereby it denotes the principal, and most intimate, of all the attributes of a thing; or that which agrees to every such thing, and such alone, and that always, and in such manner, as that the mind, with all its attention, cannot perceive any thing prior thereto; by which, essence is distinguished from the essential attributes, *i. e.* from such as flow from its essence, or first attribute. Thus, the essence of the human mind is commonly supposed to consist in the power of thinking; because all its other perfections seem to pre-suppose this; but this pre-supposes none. And thus the powers of understanding, doubting, assenting, willing, &c. do all flow from the power of thinking; and cannot exist without it, though this may without any of them.

It must be allowed, however, that the essential properties of a thing do so closely cohere, nay, and inhere, in the essence itself, that it is scarcely possible to distinguish the one from the other. Hence, what some urge, that, setting aside all the attributes and properties of a thing, and what remains is its essence, is a mere chimera. For set aside, *e. gr.* from the mind, the powers of understanding and willing, with the rest of its attributes, and what will there remain to call its essence?

It is greatly disputed, in the schools, whether the essences of created things be eternal? or whether the essences, as well as their existence, had their origin in time? The Cartesians hold, that the essences of things depend absolutely on the free concurring will of God.

ESSENCE, *Essential oil*, *Essential salt*. The essence of a vegetable, according to the old chemists, was, that one of its proximate elements, in which resided the quality of taste or odour, which peculiarly distinguished it from other vegetables, and rendered it especially applicable to pharmaceutical purposes. Thus the fragrance of orange peel, of pepper-mint, of cinnamon, was found by experience to be separable from the other parts of the vegetable, by means of distillation, &c.; the result of this process was a small portion of highly fragrant oil, in which was contained the entire odour that had been naturally dispersed through the

whole mass: hence the oil thus procured obtained the name of "essential oil." Again, most four vegetables, as fennel, lemons, &c. owe this quality to the presence of an acid, which, when separated from the other vegetable principles, assumes a crystalline appearance, and was known by the name of their essential salt. The same appellation was also given to all those vegetable principles which, when pure, are capable of crystallizing, whether they were acid to the taste or not. Thus sugar was ranked among the essential salts. The term, however, is at present obsolete. Essential oil still retains its place in chemical nomenclature, and we refer the reader to the article OILS, *essential*, for a particular account of their species and properties.

ESSENCE of *Roses*. See ROSES.

ESSENCE, *Ward's*. See WARD'S *Medicines*.

ESSENCE of *Wine*, a term used by Paracelsus, and some of the German chemists since his time, to express what is called sometimes the philosophical spirit of wine, or the spirit of wine of the ancients. It is not a distilled spirit like what we call spirit of wine, but approaches more to what Stahl has greatly recommended to the world, under the name of concentrated wine, or wine whose strength has been reduced to a smaller compass, by separating its aqueous parts only by freezing. Stahl recommends the immediately exposing of wine to the frosty air on this occasion; but the process ordered by Paracelsus for the preparation of this liquor is more tedious. He orders that the finest and best flavoured wine be chosen; that it be put into a glass, filling it up three parts in four: and the neck being then sealed hermetically, it is to be put into horse-dung for three months, and then exposed to the frosty air for a month, after which the ice is to be thrown away, and the liquid part, which is the essence, preserved. Shaw's *Chemical Essays*.

ESSENDO *Quietum de Tollonio*, in *Larw*, a writ to be quit of toll, and lies for citizens and burghesses of any city or town that by charter or prescription ought to be exempted from toll, where the same is exempted of them. Reg. Orig. 258.

ESSENEUX, in *Geography*, a town of the Netherlands, in the duchy of Limburg, situated on the Ourt; 9 miles S. E. of Liege.

ESSENI, ESSENES, or *Essians*, an ancient sect among the Jews.

As to the etymology of the name, critics have been much divided. Philo derives it from *עצום*, *holy*; Epiphanius from *ישבי*, *Jisbai*, *Jesse*, the father of David; Salmasius from a city called *Essa*, mentioned by Josephus; whence he apprehends the sect first sprung; Godwin derives it from the Syriac word *נסן*, *asa*, which signifies *to heal*; because Philo calls one branch of the Essenes *Therapeutæ*; and Serrarius enumerates at least a dozen different etymologies. Philo in *Traët. Omnis probus Liber. Oper. p. 678. Colon. Allobr. 1613. Epiphan. Hæres. xix. lib. i. Salmas. Plin. exercit. in Solin. cap. 35. Serrar. Trihæres. Jud. lib. iii. cap. 1. p. 106. 110. edit. Trigland. 1703. The principal ancient writers, who give any considerable account of the Essenes, are Josephus, Philo, and Pliny. Jos. de Bell. Jud. lib. ii. cap. i. cap. 8. & 12. and *Antiq. lib. cxiii. cap. 9. 13. 19. lib. xviii. cap. 1. & cap. 2. & alibi. Philo. ubi supra, & De Vita contemplativa, p. 688. ed. col. Allobr.**

As to the origin of this sect, Pliny asserts, without mentioning his authority, that it had subsisted for several thousand years. The most probable opinion is, that this sect was formed by Jewish exiles, a little before the time of the Maccabees, who were forced to fly from the persecution of their enemies into caves and deserts. The first Essenes we read of are mentioned in the fourth book of Maccabees, under the

name of Hasdanim, and by Josephus; both which accounts agree that they were already settled in Judæa, in the time of Jonathan, the brother and successor of Judas Maccabæus, about a hundred and fifty years before Christ. Josephus states that their number in Judæa was about four thousand, meaning, as Dr. Lardner (Works, v. i. p. 128.) suggests, those of them, that entirely rejected marriage. Philo says, that in Syria and Palestine there were about 4000 of them, but he makes the number in Egypt much greater. Philo says, that they sacrificed no living creatures, and that they shunned cities. Josephus says that they sent presents to the temple, but offered no sacrifice there. They seem therefore not to have exposed themselves much to public view, nor would they admit a man of another sect into the apartments in which they lived. Some have expressed their surprise, that no mention should be made of this sect in the New Testament. This proceeded, as some imagine, from their retired mode of living, by reason of which they never came under our Saviour's observation, as the Pharisees and Sadducees often did. Others suppose, that, being very honest and sincere, without guile or hypocrisy, they gave no reason for that reproof and censure, which the others very justly merited. It should be considered that it was the design of the evangelists to write the history of our Saviour's ministry, and not that of the Jewish sects. Prideaux observes, that almost all that is peculiar in this sect is condemned by Christ and his apostles. Prid. Conn. vol. iii. p. 384. However, it has been supposed, that they are referred to, by the apostle Paul in his epistle to the Colossians, ch. ii. 18. 21. 23.

Josephus, making mention of the several sects among his countrymen, distinguishes three; *viz.* the Pharisees, Sadducees, and Esseni; which last he prefers to the two former, as to their manner of life. He assures us, farther, that they were Jews, by original; from which it should appear, that St. Epiphanius was mistaken in ranking them among the Samaritans.

In effect, the Esseni appear to have been true Pythagorean philosophers, in every thing that related to their manner of living; for they greatly affected solitude and retirement; and avoided all conversation with women, to devote themselves more entirely to the contemplative life. Grotius will have the Esseni the same with the ancient  $\text{ἡσσηνοὶ}$ , *Hasidim*, or *Hasidai*; thus called, according to Philo, from their singular piety, humility, and devotion. Among these, Gale observes, it was, that the Hebrew philosophers chiefly flourished. Porphyry is very prolix in his praises of the Esseni:  $\text{Ἔστι τῶν αἰνῶν ἐσσηνοὶ ἰσχυροὶ μὴ τὸ γενεὸς φιλαλλέων, \&c.}$  He represents them as despisers of pleasures, riches, glory, and delicacy; and strenuous retainers to continency, austerity, study, &c. He adds, they decline marriages, and adopt and educate other people's children in the principles of religion and philosophy; they are all on a level, hold every thing in common, neither buy nor sell, &c. By long habit, they arrived at such a degree of patience, that Porphyry assures us, flames and tortures had not the least effect on them. They scorned to treat their tormentors; nor ever shed a tear; but would smile under all their agonies, &c. As to their learning, Philo Judæus, in his treatise, That every good Man is free, tells us, that they despised logic, as useless to the acquiring of virtue; physics they left to the sophists and disputants, as judging it to transcend the human faculties; and applied themselves wholly to morality. Porph. de Abst. lib. iv. § 11. seq. Gale Philos. Gener. lib. i. cap. 1. § 11.

Both Josephus and Philo give a surprising account of their austere way of life, which the curious reader may see at

large in Prideaux's Conn. ubi supra. Their houses were mean; their cloaths made of wool, without any dye; they never changed their cloaths or shoes till they were quite worn out; their food was plain and coarse, and their drink water; they neglected all bodily ornaments, and would by no means anoint themselves with oil, according to the fashion of those times. They lived in sodalities, and had all their goods in common; their morals were very exact and pure, and they kept the Sabbath more strictly than any of the Jews. Before any of them were admitted to the common table, they bound themselves by a solemn oath to observe the rules of the society, which were very strict and exemplary.

Some have said that the Essenes, as well as the Pythagoreans, prohibited oaths; that they used only inanimate sacrifices, and that they not only worshipped towards the rising sun, but worshipped the sun itself. But it has been urged, that neither of these charges seem to be well founded; or at least, that it is difficult to reconcile them with their known veneration for the writings of Moses, and other instances of their conduct. Pliny, and others on his authority, have asserted, that they wholly declined marriage; and Pliny (lib. v. cap. 17.) with more wit than justice, says, that for several thousand years, this people is perpetually propagated without any being born among them, so fruitful and prolific unto them is the repentance of others. But Josephus informs us (De Bell. Jud. lib. ii. cap. 1.) that there is one sort of Essenes, who agreed with the others, except in the article of marriage. For they reckoned, that those that do not marry cut off a great part from the number of the living, and that thus the whole race of mankind would soon be extinguished. Accordingly they made choice of those women, who, after three years trial, were found fit to bear children, and never cohabited with them after they were known to be with child; consulting the propagation of their species, and not their own gratification in this business.

With respect to the religious opinions of the Essenes, they believed the existence of angels, the immortality of the soul, and a future state of rewards and punishments, but denied the resurrection of the body. They maintained, that fate governs all things, and that nothing happens to man but by its appointment.

The Esseni seem to have been, among the Jews, what the most retired and austere monks are, or were, among the Christians: which was what gave them their denomination of  $\text{Ἰουδαϊκοὶ ἀσκητικοὶ}$ , *Jewish ascetics*.

Many Catholic writers have even deduced the origin of monks from them; building, principally, on what Philo relates of them, who divides them into two branches, or sects; the one who married, and the other who lived in celibacy.

Josephus seems likewise to have had an eye to these two sorts of Esseni: Serrarius, who has wrote very amply on the subject, follows Philo in making two classes of Esseni. The first are those whom he calls *Prædici*, and who lived in community; the second, those called *Theoretici*, who lived in solitude, and led a life of pure-contemplation. He adds, that Josephus only makes mention of the first; omitting the contemplative kind, whom Philo calls *Therapeutæ*, and who were principally found in Egypt. See *Therapeutæ*.

Eusebius holds, that the Esseni, called *Therapeutæ*, were real Christians, or Jews converted by St. Mark, who had embraced this kind of life. Scaliger, on the contrary, maintains, that these *Therapeutæ* were no Christians, but real Esseni, who made profession of Judaism; however, he

he allows of the two kinds of Esseni above-mentioned. But Valesius, in his notes on Eusebius, absolutely rejects any such distinction: he denies that the Therapeutæ were any real Esseni; and that chiefly on the authority of Philo himself, who never calls them Esseni, and who places the Esseni in Judæa and Palestine; whereas the Therapeutæ were spread throughout Greece, Egypt, and other countries.

Some traces of the Essenes are found under the emperor Trajan, and under Justinian; but they were much degenerated from their primitive purity both of doctrine and manners; and the sect about that time became extinct. Though the Therapeutæ, as well as the Essenes, were strictly Jews, and not Christians, it is not impossible, that some of them, becoming Christians, might still affect their former reclusive way of living; and being imitated by others, laid the foundation of monkery among Christians.

ESSENIAS, ANDREW, in *Biography*; a learned Dutch divine, was born at Bommel in the year 1618. He was educated chiefly at Utrecht, was admitted to the exercise of the ministry in the year 1639, and in the following year took the degree of M. A. He obtained some preferment, and took his doctor's degree in the year 1645. Soon after this, he was chosen pastor of the principal church at Utrecht, and in 1653 was appointed professor of theology at that university. He died in 1677, leaving behind him many works, that were very highly esteemed by his contemporaries. He was what the world has usually denominated an orthodox divine, and wrote against Crellius, and others among the Unitarians. One of his largest publications was "A System of Divinity," in 2 vols. His most popular piece was entitled "A short View of Theological Controversies, with an Index to Scripture Passages." This has gone through many editions. Moreri.

ESSENTIA DULCIS, in *Chemistry*, a name given by Kunkel, and some others of the German authors, to a menstruum, of which they relate wonderful effects; but the preparation of which seems hitherto a secret. They say this menstruum has nothing acid or corrosive in it, but that it approaches to the nature of spirit of wine, yet that it is capable of dissolving the most dense metals, and of converting any of them into a pure white salt, which has all their virtues, but nothing of that vitriolic acrimony, which they have when prepared in the common way. The salts of mercury and of gold thus prepared have great praises bestowed on them, and are said to cure epilepsies, the venereal disease, and many other distempers, without any violence or danger. Kunkel, De Salis Metal. See METAL.

ESSENTIAL, something that is necessary to constitute a thing, or that has such a connection with the nature and reason of a thing, that it is found, or supposed, wherever the thing itself is.

Thus, it is essential to God to be just. Mr. Locke has laboured to overturn that great principle of the Cartesians, that thinking is essential to the soul.

The heart, brain, and spinal marrow, are parts ordinarily supposed essential to life, or without which life cannot be; yet we have instances, in history, of children being found, and alive, without almost any of those parts. See BRAIN, &c.

ESSENTIAL characters, in *Natural History*, or *Diagnosics*, are such particulars as mark or distinguish a plant or animal from all others in the same genus or order. Mr. William Martin, in his "Outlines of the Knowledge of Extraneous Fossils," p. 189, states the principles under five heads, which should direct the choice of parts of a fossil animal or

plant, to be considered as its diagnostic or essential characters. See RELIQUIA.

ESSENTIAL oils. See OILS.

ESSENTIAL properties, are such as necessarily depend on and are connected with, the nature and essence of any thing, so as to be inseparable from it; in distinction from accidental.

ESSENTIAL salts, are those prepared from decoctions, or those which are found crystallized in the juices and infusions of plants; in contradistinction to those made by incineration. See SALT.

ESSENTIAL Fever, Form, Mode, Part, Perfection. See the substantives.

ESSEQUEBO, or Esquivo, in *Geography*, one of the four provinces into which the Dutch possessions in Guiana are divided; the other three being Surinam, which is the chief settlement, Berbische or Berbiz, and Demerara. This settlement derives its name from that of the large river on which it is situated, and which at its discharge into the Atlantic is 3 leagues wide. The productions of this country are sugar, coffee, and cotton. See GUIANA, SURINAM, BERBISCHE, and DEMERARA.

ESSERA, a river of Spain, which runs into the Cinca, in Arragon.

ESSERA, ESSERE, or Sere, in *Medicine*, a generic denomination, used by the Arabian physicians, and comprising several popular eruptions, and rashes, which appear on the skin: especially the eruption of the summer season, in warm climates, which has been termed the PRICKLY-heat, the NETTLE-rash, the PRURIGO of Dr. Willan's classification; &c. See these articles. See also Willan on Cutaneous Diseases, genus Lichen.

ESSERUM, in *Geography*, a small town of Denmark, in the island of Zealand, in the district of Cronburg, and the herred of Holboe. Before the Reformation it was remarkable for a rich monastery of Bernardines, founded in 1150, in an extremely pleasant country, watered by lakes abounding in fish. But Esserum is now much more interesting for a royal stud of horses, and for having constantly flocks of the most renowned foreign sheep, Spanish and others, which are distributed among the farmers to improve the Danish breed. In the beginning of the year 1800, there were at Esserum 652 choice sheep, of which 223 ewes, and 33 rams, were Spanish of the best Merino breed. Cateau Tableau des Etats Danois, vol. ii. p. 147.

ESSE, in *Military Language*, are fixed to draught chains, made in the form of an S; one end of which is fastened to the chain, and the other to hook to the horse's harnesses, or to a staple; they serve likewise to lengthen and piece chains together.

ESSEX, in *Geography*, the name of one of the English counties, which has for its boundaries the German ocean and river Thames to the east and south; the counties of Suffolk and Cambridge to the north; and those of Middlesex and Hertfordshire to the west. The area of land thus encompassed measures about sixty miles in length from east to west, by fifty from north to south: its circumference being about 215 miles. It is divided into 20 parts, of which fourteen are hundreds, five half hundreds, and one a royal liberty. These are subdivided into about 400 parishes and townships, and twenty-five towns; containing, according to the late official report, 39,398 houses, and 226,437 inhabitants. When the Romans invaded Britain, this district, with that now denominated Middlesex, were inhabited by a class or tribe of the Britons, called Trinobantes, or Trinovantes, who possessed, according to Cæsar, and some other ancient writers,

ters, two considerable cities or fortified towns; one, the site of modern London; and the other, that of Colchester in this county. This tribe was the first to submit to and become vassals to the Romans, who, to keep them in subordination, established five military stations within this district. These were Duroplitum, Cæsaromagus; Canonium, Camalodunum, and Ad Ansam. These stations were all seated on the road which formed the fifth Iter from Londinium to Venta Icenorum, Caistor in Norfolk. Camalodunum was unquestionably the principal station in Essex, and though its site has been much contested by different writers, an attentive examination of the several places assigned, combined with a knowledge of the antiquities discovered in the vicinity of each, will admit little doubt of Colchester being the real situation. Essex formed a separate and distinct kingdom during a certain period of the Saxon Heptarchy, and was called East-Seaxa; but the times of its establishment and termination are not precisely authenticated. Turner states that this district, and East Anglia, were originally occupied by the Saxons at nearly the same period; and that Erkenwin was the first king of the former; commencing his reign in 527, and dying in 587.

By the Domesday-book it appears, that ninety land-owners of this county were deprived of their lands by the Conqueror, during whose reign the whole civil and ecclesiastical establishment of the kingdom, and of each county, underwent very considerable changes. Essex was now governed and tyrannized over by Norman barons, who constructed castles on their estates to secure themselves, and to awe their dependant vassals. In the civil wars between the houses of York and Lancaster, and in those of Charles's time, this county suffered greatly from the interference of the De Vere's in the former, and during the long siege of Colchester in the latter. Formerly there were twelve castles, or fortified buildings in this county; two of which, Landguard fort, and Tilbury fort, were denominated royal castles, as built for national security: the others were baronial residences, *viz.* Colchester, Hadleigh, Canfield, Hedingham, Clavering, Ralegh, Ongar, Pleshy, Stanstead-Montfichet, and Walden. These formidable fortresses, though once the pride of the nobility, and the terror of the peasantry, are mostly rased to the ground; the only parts remaining being their high keeps and wide fosses. At Colchester, Hadleigh, Hedingham, and Walden, some parts of the walls still remain. Essex composes part of that tract of country on the eastern side of England which forms the largest connected space of level ground in the whole island; not one lofty eminence or rocky ridge being found in several contiguous counties. The surface of Essex is not, however, totally flat, having many gentle hills and dales; and towards the north-west, whence most of the rivers proceed, the country rises, and presents a continued inequality of surface. The most level tracts are those of the southern and eastern hundreds. The sea-coast is broken into a series of islets and peninsulas, deeply cut in by arms of the sea, and exhibiting evident tokens of the force and effects of that restless element. Extensive salt marshes border most of the coast, the greater part of which is protected by embankments. The banks of the Thames, and the lower part near the sea, are likewise low and marshy. This county lies under a proverbial imputation of being particularly unhealthy; but this character can only apply to a small part of it; as the middle and northern districts are justly noted for a dry soil, and a wholesome clear air. That part known by the name of the hundreds of Essex, bordering on the south coast, from its low and marshy situation, and exposure

to the easterly winds and sea fogs, is certainly injurious to health, and many intermitting fevers proceed from these causes.

The principal productions of this county are wheat, barley, oats, beans, peas, turnips, tares, rape, mustard, rye-grass, and trefoil. Many districts on the east side are extremely productive; wheat is not unfrequently found to rise to a load an acre; oats, (particularly the Poland,) to eleven or twelve quarters; beans and other corn in proportion. Among the more rare plants cultivated in Essex, are those of coriander, teasel, and carraway; many acres are also appropriated to the produce of hops, and various horticultural plants and roots. The latter are confined to the vicinity of large towns, and to the lands adjoining to the metropolis. Almost every species of soil is to be found within the limits of Essex, from the most stubborn to the mildest loam. The north-west side is characterized by a chalky substratum; but the east and south sides abound with marshy and boggy land, having abundance of gravel intermixed. Of waste lands and forests, Messrs. Griggs (in their "General View of the Agriculture of Essex,") computed the county to contain fifteen thousand acres; the greater part of which, they observe, is capable of producing corn. Since their report, however, many districts have been inclosed and cultivated. Though Essex is not highly celebrated for its dairies, yet those in the parish of Epping and its vicinity are famous for the richness of their cream and butter. The butter is mostly sent to London, where it bears a high character and price. Few counties have less minerals than Essex; which is also nearly exempt from quarries, or any mass of rocks. In consequence, the houses are almost wholly built with brick; and many of them are singular and curious specimens of brick-architecture. In constructing the castles, the monastic buildings, and many of the old mansion-houses, the builders have endeavoured to render them not only durable monuments of their skill, but also examples of their taste, displayed by a variety of ornaments in the cornices, doors, pilasters, and particularly in the chimnies. Some mineral waters rise in the county, but few have obtained much repute; that of Tilbury is occasionally resorted to, and found to be impregnated with some earthy and muriatic salts.

The principal rivers, properly belonging to this county, are the Colne, the Blackwater or Pant, the Clelmer, the Crouch, the Ingerbourn, the Roding, and the Cam. Besides these, Essex partakes of other rivers, which serve as natural boundaries, and irrigate and fertilize its land: these are the Thames, the Lee, or Lea, the Stort, and the Stour.

In the early periods of our history, it is reasonably presumed, that the whole, or the greater part of Essex, was one extensive forest. During the British and Roman governments, many parts must have been cleared for stations, roads, and cultivation: yet in the time of king Stephen it appears that the principal portion of the county was either forest, or subject to forest laws. In his reign, however, a large tract in the north-east part of the county was disafforested, and cultivated; and the remaining part, north of Stane-street, was disafforested by king John. Henry the Third, in the twelfth year of his reign, directed perambulations to be taken of Waltham forest, in order to ascertain its extent and value; and about the same time had large tracts cleared for the plough. This judicious plan was pursued by Edward the First, in the twenty-sixth and twenty-eighth years of his reign: yet much forest land still remained; and Paul, viscount Bayning, with many other gentlemen of the county, purchased of the crown, and disafforested

several

Several parts of it. These proceedings, combined with the more equitable decisions of subsequent monarchs, occasioned the forests to contract their boundaries, and be less injurious to the public. While the forests continued in the crown, and were under the local government of arbitrary foresters and stewards, the subject, whose estate was contiguous, suffered repeated oppressions. The grievance was partly redressed in the perilous reign of king John, when the barons compulsively procured from that monarch the "Charter of Forests," by which many of these royal districts were disafforested, and stripped of their oppressive privileges; while more lenient regulations were adopted in the government of those that remained. The forests of Epping and Hainault still retain the name, and support a few deer, &c. The office of chief forester for Essex was deemed highly honorary, and was generally bestowed on some illustrious person. The stewardship was also an office of great consequence, and was usually enjoyed by some of the nobility. It continued in the De Veres, earls of Oxford, for many generations, but was taken from them by Edward the Fourth, on account of their adherence to the Lancastrian party. On the accession of Henry the Seventh, it was restored by grant to John, earl of Oxford. The steward had power to substitute a lieutenant, one riding-forester, and three yeomen-foresters, in the three bailiwicks of the forest. He also had many lucrative privileges, and was keeper of Havering at Bower, and of the house and park there.

Previous to the dissolution, Essex contained forty-seven religious houses; of these, two were mitred abbies; six common abbies; twenty-two priories; three nunneries; three colleges; two preceptories of templars; and nine hospitals.

Essex is included in the diocese of London, and contains three archdeaconries and fifteen deaneries; it returns eight members to parliament, *viz.* two for the county, two for Malden, two for Harwich, and two for Colchester; it is in the home circuit; pays twenty-four parts of the land-tax, and supplies 960 men for the militia.

ESSEX, one of the most populous and best cultivated counties in Massachusetts, in the United States of America; bounded N. by North Hampshire, E. and S. by the ocean, and the town of Chelsea in the county of Suffolk, and W. by Middlesex county; 38 miles long and 25 broad; of a triangular shape, Chelsea being the acute point. It is subdivided into 22 townships, containing 7644 houses, and 61,196 inhabitants, about 135 to each square mile. The first settlement in Massachusetts proper was made in Salem, the capital of this county, in 1628, and it was made a shire in 1643, being one of the three into which the colony was divided. Essex county pays about  $\frac{7}{8}$ th part of the state-tax, elects six senators for the government of the commonwealth, and two representatives in the legislature of the United States. The principal towns are Salem, Newbury-port, Gloucester, Marblehead, Beverly, Newbury, and Ipswich; and in it are two academies, one at Byfield, and another at Andover. The face of the county is agreeably variegated with hills, vales, plains, and woods; the land is generally fruitful, but more suited to the culture of barley than most other parts of the state; it has quarries of marble and limestone, and the coast is indented with a number of good harbours. The north part of Essex county is intersected by Merrimack river; and between it and the North Hampshire line is a strip of land three miles wide, divided into the towns of Methuen, Haverhill, Almsbury, and Salisbury, containing 1429 inhabitants. The chief island on the coast of this county is Plum island.

ESSEX, a county in Upper Canada, bounded on the E.

by the county of Suffolk, on the S. by lake Erie, on the W. by the river D'Etroit to Maissonville's mill, thence by a line running parallel to the river D'Etroit and lake St. Clair, at the distance of four miles; till it meets the river Thames, and thence up the said river, to the N.W. boundary of the county of Suffolk. This county sends one representative to the provincial parliament.

ESSEX, a county in Virginia, bounded E. and N.E. by Rappahannock river, which divides it from Richmond county; about 55 miles in length and 12 in breadth, and containing 3741 free inhabitants, and 5767 slaves.

ESSEX, a county in New Jersey, situated in the eastern part of the state, and separated from Staten island by Newark bay. It is about 25 miles in length and 16 in breadth, and has three townships, *viz.* Newark, Elizabeth-town, and Acquackanack, containing 22,269 inhabitants, of whom 1521 are slaves. The soil is fertile, and its productions find a ready sale in the city of New-York. This county comprehends seven Presbyterian churches, three for Episcopalian, one for Anabaptists, and two for Dutch Calvinists.

ESSEX, a county of New-York, having on the north Clinton county, on the south Washington county, and on the east lake Champlain, which separates it from Vermont.

ESSEX, a county in Vermont, bounded N. by Canada, and E. by Connecticut river, containing 1429 inhabitants.

ESSEX, a township in Chittenden county, in Vermont, containing 729 inhabitants, and lying between Jericho on the S.E. and Colchester on the N.W.

ESSEX Valley Mountains, mountains of the island of Jamaica; 10 miles S.S.E. of Lacovia.

ESSEY, a town of France, in the department of Orne, and district of Alençon; 3-leagues N.E. of Alençon.

ESSLISORS. See ELISORS.

ESSOIGN, or ESSOIN, in Law, an excuse for him who, being summoned to appear and answer to an action real, or to perform suit to a court baron, &c. cannot attend, because of some legitimate hindrance.

The word is formed of the French *essoine*, or *exoine*; and that from the barbarous Latin *essonia*, or *exonia*, which signifies the same.

The causes that serve to essoin, are various; yet they may be reduced to five heads. The first is, *essoin de ultra mare*, when the party is beyond sea; by which the defendant shall have 40 days: the second, *de Terra Sancta*, when on an expedition in the Holy Land, and the defendant shall have a year and a day; the third, *de malo veniendi*, when he is infirm of body, and cannot come; which is also called the common essoin; the fourth, *essoin de malo lecti*, when the defendant is sick a-bed, and may by writ be viewed by four knights; the fifth, *de servitio regis*, when he is in the king's service. Besides these, there are several other excuses to save a default in real actions, as constraint of enemies, floods of water, &c. 2 Co. Inf. 125.

ESSOIGN day of term, is the first day of that term when the court sits to take essoigns, or excuses, for such as do not appear according to the summons of the writ; *i. e.* the octave of St. Hilary, or the eighth day inclusive after the feast of that saint; which falling on the 13th of January, the octave, therefore, or first day of Hilary term, is the 20th of January. But the person summoned hath three days grace beyond the return of the writ, in which to make his appearance; and if he appear on the fourth day inclusive, the *quarto die post*, it is sufficient.

ESSOIGN de malo villa, is when the defendant is in court the first day, but gone without pleading; and being afterwards surprised with sickness, &c. cannot attend, but sends two essoigners, who openly protest in court that

he is detained by sickness in such a village, that he cannot come *pro lucrari et pro perdere*; and this will be admitted: for it lieth on the plaintiff to prove, whether the effoign is true or not.

ESSOIGNS, *Clerk of the*. See CLERK.

ESSOMMES, in *Geography*, a small town of France, in the department of the Aisne, on the river Marne; 3 miles S.W. of Château Thierry.

ESSONE, a river of France, in the department of Seine and Oise, which has its source near Pithiviers in the forest of Orleans, flows by Ferté Alais, receives the Juine near Saint Vrain, 3 miles above Villeroi, and falls into the Seine near Corbeil. It has lately been rendered navigable.

ESSONNE, a small town of France, in the department of Seine and Oise, near the river Essone, 24 miles S. of Paris, and 24 miles N. of Fontainebleau, remarkable for its manufactures of gunpowder and of writing paper.

ESSORANT, from the French *essorer*, to air, in order to dry, in *Heraldry*, a term used to express a bird standing on the ground with the wings expanded, as if it had been wet, and were drying itself.

ESSOYES, in *Geography*, a small town of France, in the department of the Aube, chief place of a canton in the district of Bar-sur-Seine, with a population of 1585 individuals, 15 miles S.W. of Bar-sur-Aube. Its canton contains 21 communes, and 11,655 inhabitants, on a territorial extent of 375 kilometres.

ESTABLISHMENT of *Dower*, in *Law*, is the assurance or settlement of dower made to the wife by the husband on marriage; and *assignment of dower* signifies the setting it out by the heir afterwards, according to the establishment. See DOWER.

ESTABLISHMENT of *Religion*. See RELIGION.

ESTACHE, is used in our *Old Writers*, for a bridge or flank of stone and timber.

ESTAFFLISCHEN, in *Geography*, a town of Poland, in the palatinate of Kalish; 14 miles N.E. of Kalish.

ESTAFORT, a town of France, in the department of the Lot and Garonne, and district of Agen; 3 leagues S. of Agen.

ESTAGEL, a town of France, in the department of the Eastern Pyrenées; 3½ leagues N.W. of Perpignan.

ESTAGNAC, a small town of France, in the department of the Charente; 33 miles E. of Angoulême.

ESTAIN. See ETAIN.

ESTAING, a small town of France, in the department of the Aveyron, chief place of a canton in the district of Espalion, with a population of 1075 individuals. It is situated 18 miles N. of Rhodéz. Its canton contains 12 communes and 6700 inhabitants on a territorial extent of 195 kilometres.

ESTAIRE, a small town of France, in the department of the North, on the river Lys, between Merville and Armentières; 15 miles W. of Lille.

ESTAMBOLIC, or ISTAMBOL-ANTIR, a town of Arabia, in the sheriffal of Mecca, near the coast of the Red sea; 180 miles N.N.W. of Medina.

ESTAMPES. See ETAMPES.

ESTANDARD. See STANDARD.

ESTANFORDE, in *Geography*, a town of Flanders; 12 miles S.W. of Ypres.

ESTAPA, or ISTAPO, a town of North America, in Mexico, and province of Tabasco, situated on a river of the same name; 10 miles S.W. of Villa Hermosa.

ESTAPLES. See ETAPLES.

ESTAPO, a strong town of America, in New Spain, inhabited by Spaniards and native Americans, situated at

the mouth of the river Tlaluc. N. lat. 17° 30'. W. long. 103° 5'.

ESTARREJA, a town of Portugal, in the province of Beira; 18 miles S. of Oporto.

ESTATE, in *Law*, the title or interest which a man hath in lands or tenements, &c. An estate in lands, tenements, and hereditaments, signifies (says judge Blackstone) such interest as the tenant hath therein; so that if a man grants all *his estate* in Dale to A. and his heirs, every thing that he can possibly grant shall pass thereby. (Co. Litt. 345.) It is called in Latin *status*, signifying the condition or circumstance in which the owner stands with regard to his property. For ascertaining this with accuracy, estates may be considered in a three-fold view: first, with regard to the *quantity of interest* which the tenant has in the tenement; secondly, with regard to the *time* at which that quantity of interest is to be enjoyed; and, thirdly, with regard to the *number and connexions* of the tenants.

I. The *quantity of interest* which the tenant has in the tenement is measured by its duration and extent. Thus, either his right of possession is to subsist for an uncertain period, during his own life, or the life of another man; to determine at his own decease, or to remain to his descendants after him; or, it is circumscribed within a certain number of years, months, or days; or, lastly, it is infinite and unlimited, being vested in him and his representatives for ever. This occasions the primary division of estates, into such as are *freehold*, and such as are *less than freehold*. See FREEHOLD.

Estates of freehold, understood as they are defined under that article, are either estates of *inheritance*, or estates *not of inheritance*. The former are again divided into inheritances *absolute* or fee-simple, and inheritances *limited*, one species of which is usually denominated fee-tail. See FEE-SIMPLE, and FEE-TAIL.

Of estates of freehold, not of inheritance, but *for life only*, some are *conventional*, or expressly created by the acts of the parties; others are merely *legal*, or created by construction and operation of law. As to estates for life, expressly created by deed or grant; see LIFE-ESTATE. As to the estate of tenant in tail after possibility of issue extinct; see TAIL and FEE-TAIL. As to tenant by courtesy, and tenant in dower; see TENANT and DOWER.

Of estates that are less than freehold, there are three sorts; *viz.* 1. Estates for years; 2. Estates at will; 3. Estates by sufferance. For the two former, see LEASE; and for the latter, see SUFFERANCE.

Besides the several divisions of estates above enumerated, in point of interest, there is another species which is called an estate *upon condition*; being such whose existence depends upon the happening or not happening of some uncertain event, whereby the estate may be either originally created, or enlarged, or finally defeated. (Co. Litt. 201.) Estates upon condition are of two sorts: 1. Estates upon condition *implied*; 2. Estates upon condition *expressed*: under which last may be included, 3. Estates held in *vadio, gage, or pledge*; 4. Estates by *statute-merchant* or *statute-staple*; 5. Estates held by *elegit*. See these several articles.

II. Estates, with regard to the *time of their enjoyment*, when the actual receipt of the rents and profits commences, may be considered either in *possession* or in *expectancy*; as to estates in possession, sometimes called estates *executed*, whereby a present interest passes to and resides in the tenant, not depending on any subsequent circumstance or contingency, as in the case of estates *executory*; all those above-mentioned are of this kind; but the doctrine of estates in *expectancy* contains, says Blackstone, some of the nicest and

most abstruse learning in the English law. Of expectancies there are two sorts; one created by the act of the parties, called a *remainder*; the other by act of law, and called a *reversion*. See *REMAINDER* and *REVERSION*. See also *EXECUTORY Devise* and *LIMITATION*.

III. Estates considered with respect to the *number and connexions* of their owners, or the tenants who occupy them, whatever be their quantity or length of duration, and whether they be in actual possession, or expectancy, may be held in four different ways: *viz.* in *severalty*, in *joint-tenancy*, in *coparcenary*, and in *common*. See *SEVERALTY*, *JOINT-TENANCY*, *COPARCENARY* and *PARCENERS*, and *TENANTS in common*.

With regard to the title to estates and the different modes of tenure; see *TITLE* and *TENURE*.

Estates are acquired divers ways, *viz.* by descent from a father to the son, &c. conveyance or grant from one man to another; by gift or purchase, deed, or will; and a fee-simple is the largest estate that can be in law. 1 Litt. 541.

Estates are real, of lands, &c. or personal, of goods and chattels; otherwise distinguished into freeholds that descend to the heir, and chattels, which go to the executors. The word estate, generally, in deeds, grants, and conveyances, comprehends the whole, in which the party hath an interest or property; and will pass the same. 3 Mod. 46.

ESTATE, *additions of*. See *ADDITION*.

ESTATE, *base*. See *BASE*.

ESTATE, *que*. See *QUE estate*.

ESTATE, or simple *State*, denotes also the empire, kingdom, provinces, or extent of lands under the government of any sovereign.

The estates of the grand seignor, of the king of Spain, &c. are very extensive; those of the king of France were before the revolution compact, and well peopled. Italy was formerly cantoned out into a great number of petty states. We say, ministers of estate, secretaries of state, &c.

ESTATE, or *State*, is also generally applied in the same sense with class or order; thus, the lay part of his majesty's subjects, or such of the people as are not comprehended under the denomination of clergy, may be divided into three distinct estates or states, the civil, the maritime, and the military. See each term.

ESTATE is more particularly applied to the several ranks or classes of a people assembled together, for concerting measures, reforming public abuses, or composing the disturbances of a state. In England, the three estates, *viz.* king, lords, and commons, meet ordinarily in parliament. See *PARLIAMENT*.

ESTATES *General*. } See *STATES General*, &c.

ESTATES *of Holland*. }

ESTAVAYER, in *Geography*, a small town of Switzerland, in the canton of Fribourg, pleasantly situated on the eastern shore of the lake of Neuchatel, N. lat. 46° 46'.

ESTE, a town of Italy, in the Paduan; 11 miles S.S.W. of Padua.

ESTELLA, a handsome manufacturing town of Spain, in Navarre, with an university in its neighbourhood, founded A.D. 1565. It contains several churches and convents, and 4500 inhabitants, defended by a castle, situated in a plain, watered by the rivers Ega and Ureder; 6 leagues S.W. of Pampeluna. The environs of this place are agreeable and fertile.

ESTELMUR, a town of Asiatic Turkey, in the province of Caramania; 120 miles S. of Cogni.

ESTENIDE. See *EKSENIDE*.

ESTEPA, a town of Spain, in the province of Seville,

or, according to some geographers, in that of Granada; celebrated for its olives and oil; 15 miles S. of Ecija.

ESTEPONA, a small fishing town of Spain, situated near the coast in the province of Granada, between Gibraltar and Marbella. Its territory furnishes abundance of wine.

ESTERLING, or *EASTERLING*. See *STERLING*.

ESTERNAY, in *Geography*, a small town of France, in the department of the Marne, chief place of a canton in the district of Epernay, with a population of 835 individuals. Its canton has 23 communes and 6498 inhabitants, upon a territorial extent of 325 kilometres.

ESTETE, in *Heraldry*, is used by the French to signify a beast whose head has been, as it were, torn off by force, and, consequently, the neck left rough and fugged; in contradistinction to *deffait*, or *decapité*, where the neck is left smooth, as if the head had been cut off.

ESTEVE, M. in *Biography*, a writer on the theory of music, or rather of sound or harmonics. He has attacked the demonstration of the principles of harmony by Rameau, in which M. Laborde allows him to have reason on his side: however, as he does not build his scale by the triple progression of Pythagoras, in the way which the abbé Rousfier prefers, and without which series of perfect fifth he thinks there never was nor ever can be any music fit to be heard, M. Esteve has not been honoured with the seal of Messrs. Laborde and Rousfier's approbation. He has, however, explained the cause of more and less perfection in concords, from the coincidences of vibration, which has been known ever since the time of Galileo, (see *BASSE fondamentale*), but never so clearly explained in France.

ESTHER, a canonical book of the Old Testament; denominated from a celebrated Jewish captive of that name, in Persia, whose beauty preferred her to the bed of Ahasuerus (supposed by some to have been Darius Hystaspis, by others Xerxes, but probably Artaxerxes Longimanus, though Jacob. Capellus makes him to be Ochus, called in Persia Achahsch-Verosh), and the throne of Persia; and who, in that quality, saved her countrymen, the Jews, from the death to which Ahasuerus had doomed them, by the counsels of his favourite Haman; who wished thus to be revenged on Mordecai for withholding from him that respect to which he conceived himself entitled. Mordecai informed the queen of the danger to which her nation was exposed; and induced her to wait upon the king, and invite him and Haman to a sumptuous banquet which she had prepared. Haman was puffed up with this high honour, and thought himself sure of accomplishing his ample scheme of vengeance. During the interval, the king chanced to read the public records, which reminded him of Mordecai's having discovered a conspiracy that had been formed against him. Determined to distinguish him by some signal token of favour, he ordered Haman to conduct Mordecai in triumph through the city. The queen having discovered to Ahasuerus, that she belonged to the Jewish nation, intreated justice against Haman on behalf of her people, for the destruction of whom he had obtained the king's decree. Ahasuerus ordered Haman to be hanged on the gallows which he had erected for the execution of Mordecai; revoked the decree issued forth against the Jews, and granted another, by which he permitted them to avenge themselves on their enemies on the day appointed. After the death of Haman, the king bestowed his estates upon Mordecai, and admitting him into his confidence, as the acknowledged uncle of the queen, advanced him to a station of high office and trust in his court. The history of this transaction makes the subject of the book of Esther. Edler was of the tribe

of Benjamin, and a descendant from one of those families, which had been carried into captivity by Nebuchadnezzar, king of Babylon, and afterwards settled in the city of Shushan. She was the niece of Mordecai, and her Jewish name was "Hadassah."

The critics are divided about the author of this book: St. Epiphanius, St. Augustine, and Isidore, attribute it to Ezra; but Eusebius will have it to be of a later date. Some ascribe it to Joachim, high priest of the Jews, and grandson of Josedek; others will have it composed by an assembly, or synagogue, of the Jews, to whom Mordecai wrote letters, informing them of what happened. *Esth.* ix. 29.

But the generality of interpreters, Hebrew, Greek, Latin, &c. ascribe the book to Mordecai himself; Elias Levita, in his *Maff. Hamum.* pref. 3. mentions this opinion as unquestionable.

It is chiefly founded on that passage, chap. ix. ver. 20. where it is said, that "Mordecai wrote these things, and sent letters unto all the Jews, that were in all the provinces, &c." It is also supposed that queen Esther herself might have some share therein: it being expressed in the same chapter, ver. 29. that Esther and Mordecai wrote a second letter, by the king's authority, to ordain the solemnizing a yearly feast, called *purim*, that is, *day of lots*, in commemoration of the Jews being delivered from the lots, or *sortes*, whereby they had been condemned.

Some will have this book to be deuterocanonical, or apocryphal; others contend for its being canonical, as far as chap. x. ver. 3. inclusive; and all the rest deuterocanonical. Of this sentiment are, St. Jerome, De Lyra, Dionysius the Carthusian, Cajetan, and others. The council of Trent turned the scale for its being canonical throughout; so that the matter is determined for the Catholic countries.

But the Protestants retain the old opinion, and only admit it as far as the third verse of the tenth chapter; the rest, to the end of the sixteenth chapter, is thrown among the apocryphal books. See CANON and APOCRYPHA.

ESTHER *Town*, in *Geography*, a town of America, in the county of Lancaster, and state of Pennsylvania, situated on the east bank of the Susquehannah river, a little N. of Harrisburg.

ESTHIO'MENOS, (from *estho*, to eat,) in *Surgery*, the disease called herpes exedens. Also any obstinate ulcer, which continues to eat away the parts.

ESTHONIA, in *Geography*, is the ancient name of the Russian government of Reval, on the southern coast of the gulf of Finland, over-against Finland Proper. In the year 1386 Esthonia was sold to the Teutonic order, and formed a part of Livonia; with which, after a separation of a hundred years, when it was under the dominion of Sweden, it was united to the Russian territory.

Not only the government of Reval, but also the greater part of Livonia, or five circles of the government of Riga, are inhabited by Esthonians. In the former they probably amount to 180,000, in the latter to 257,000 individuals. The language, manners, complexion, dwellings, and husbandry of the Esthonians prove their relationship to the Finns, who are one of the most far spread nations of the globe, extending from the shores of the Baltic to the remotest confines of Asia. In the Russian annals, where they act a considerable part, as they, in common with the Novgorodian Slavs, founded the Russian state, the Esthonians are called *Ishudes*. Tooke's *View of the Russian Empire*, vol. i.

ESTIÆA, *Εστιæα*, in *Antiquity*, solemn sacrifices to Vesta, called in Greek *εστιæα*, of which it was unlawful to

carry any away, or communicate any part to any beside the worshippers. Potter, *Archæol. Græc.* lib. ii. cap. 20. tom. i. p. 396.

ESTIATORES, *Εστιατορες*; among the Athenians, persons appointed by lot to provide an entertainment for the whole tribe. Besides those appointed by lot to this office, others voluntarily undertook it to ingratiate themselves. Potter, *Archæol. Græc.* lib. i. cap. 15. tom. i. p. 86.

ESTIMIONE, in *Natural History*, a name by which some call the *harmefion*.

ESTISSAC, in *Geography*, a small town of France, in the department of the Aube, chief place of a canton in the district of Troyes, with a population of 1255 individuals. Its canton has 6089 inhabitants, dispersed in 10 communes, on a territorial extent of 200 kilometres.—Also, a small town of France, in the department of the Dordogne, 18 miles N. E. of Bourdeaux.

ESTIVAL, a town of France, in the department of the Vosges, and district of St. Diey; 2 leagues N. of St. Diey.

ESTIVAL *occident*. See OCCIDENT.

ESTIVAL *orient*. See ORIENT.

ESTIVAL *solstice*. See ÆSTIVAL, and SOLSTICE.

ESTIVAREILLES, in *Geography*, a town of France, in the department of the Allier, and district of Montluçon; 5 miles N. of Montluçon.

ESTIUS, WILLIAM, in *Biography*, a learned Dutch divine, was born at Gorcum in Holland in the year 1542. He received the early part of his education at Utrecht, and finished his studies in philosophy and theology at Louvain, where he afterwards became an instructor. In 1580 he was admitted to the degree of doctor in divinity, and was successively chosen professor of theology, in the university of Douay; superior of that seminary, and afterwards its chancellor. He died in 1613 at the age of 71, while he was in the discharge of the various duties of his laborious office at Douay, highly esteemed on account of his modesty, piety, and active virtues. He had ever been indefatigable in his studies, and zealous in promoting the interests of those committed to his care. As an author his principal works are, "Commentarii in omnes S. Pauli et VII. Catholicas Apostolorum Epistolas," in two volumes folio. "Annotationes in præcipua ac difficiliora S. Scripturæ Loca." Another work is mentioned with much applause, it is a discourse "Contra Avaritiæ Scientiæ," intended to expose those who lock up their learning in their closets, and refuse to communicate it to the public by useful writings, or to individuals by well-timed and seasonable advice. The writings of Estius are recommended by Du Pin as exceedingly useful to young theologians in their enquiries after truth. Moreri.

ESTOILE'. A cross estoilé is a star with only four long rays, in manner of a cross; and accordingly broad in the centre, and terminating in sharp points.

ESTOILLE, PETER DE L', in *Biography*, who flourished towards the close of the sixteenth century, was educated to the profession of the law, and became grand audiencer of the chancery of Paris. He died in 1611, and after his death was published from his manuscripts "A Journal of the reign of Henry III." which has passed through many editions; of these the last was edited by the Abbé Lenglet du Fresnoi in 5 vols. 8vo. The same learned editor gave to the public "L'Estoille's Journal of the reign of Henry IV." in four volumes, 8vo. This, as well as the other work, is enriched by some curious pieces not to be found in the preceding editions. The style and manner of these journals possess much simplicity, exhibiting the air of

truth,

truth, and affording a lively and accurate picture of the times. Moreri.

ESTOILLE, CLAUDE DE L', son of the preceding, was a poet, and admitted a member of the French academy in the year 1632. He was patronized as a dramatic writer by Richlieu, but his pieces were not well received by the public, though he is allowed to have had a talent at versification, and a thorough knowledge of the rules of the stage. He was a rigid censor of his own performances, and of those of others, and is said to have occasioned the death of a young author by the severity of his criticism on a comedy put into his hands. He died in 1652 about 50 years of age. He had obtained, and richly deserved, the character of an honourable and truly independent man. In the earlier part of life, though ill provided for with respect to fortune, he chose to quit the capital with a wife whom he loved, rather than submit to the meannesses which men of letters are too much inclined to practise in courting the opulent. Moreri.

ESTOPPEL, formed of the French *estouper*, *oppilare*, *obstipare*, to stop, or block up, in *Law*, an impediment, or bar of action, arising from a man's own act, or deed; against which a man is forbidden, by law, to speak, though it be to say the truth. See BAR.

Goddard defines an estoppel to be any bar, or hindrance, to one to plead the truth; and extends it not only to the impediment given by his own act, but by another's also. There are three kinds of estoppel; *viz.* by matter of record, by matter in writing, and by matter in pais.

ESTOVERS, is used by Bracton, (l. iii. tr. 2. c. 18.) for that sustenance which a man, committed for felony, is to have out of his lands, or goods, for himself and his family, during imprisonment.

In stat. 6 Edw. 1. it is used for an allowance in meat, or cloaths. In some manors the tenants have common of estovers; that is, necessary botes, or allowances, out of the lord's wood; in which last sense, estovers comprehends house-bote, hay-bote, and plow-bote; so that if a man have in his grants these general words, "de rationabili estoverio in boscis, &c." he may thereby claim all three.

Estovers is also used for alimony, which if the husband refuses to pay, there is, besides the ordinary process of excommunication, a writ at common law, "de estoveriis habendis," in order to recover it.

ESTOURMELLES, in *Geography*, a town of France, in the department of the North, and district of Cambray;  $1\frac{1}{2}$  league E. of Cambray.

ESTOUTEVILLE, a small town of France, in the department of the Lower Seine, 12 miles N. of Caudebec.—Also, a small town of France, in the same department, 15 miles N. of Rouen.

ESTRAC, in the *Manege*, signifies a horse that is light bodied, lank-bellied, thin flanked, and narrow-chested. See BELLY.

ESTRADE, a French term, literally signifying a public road, or highway. Hence the military phrase, *battre l'estrade*, to beat the estrade, that is, to send scouts, or horsemen to get intelligence, to learn the dispositions of the enemy, and inform the general of every thing likely to fall in the way. An army never marches without sending batteurs d'estrade on every side.

The word is formed of the Italian *strada*, street, or road; which is derived from the Latin *strata*, a paved street. Some derive it from *estradiots*, who were cavaliers anciently employed in beating the estrade.

ESTRADE is also used for a little elevation of the floor of a room, frequently encompassed with an alcove, or rail, for

placing a bed in; and sometimes, as in Turkey, only covered with fine carpets, for receiving visitors of distinction.

ESTRADES, GODFREY Count of, in *Biography*, was at an early age designed for the profession of arms, and served under prince Maurice in Holland, with whom he acted as agent of the French court, and afterwards attained the high honour of marshal of France. He was highly esteemed as a diplomatic character, and in the year 1661 went to England as ambassador extraordinary, where he maintained with spirit the precedence of the crown of France to that of Spain. In the following year he went to Holland in the same character, and concluded the peace of Breda. He was intrusted with the important negotiation for a general peace at Nimeguen, and acquitted himself to the satisfaction of all concerned. He sustained with high reputation various other diplomatic characters, and in 1685 was nominated governor to the duke de Chartres, but died within a few months, at the age of seventy-nine. The count left behind him an abundance of MSS. concerning the different negotiations in which he had been engaged: from these, which consisted of twenty-two volumes folio, a collection was published in 1709, entitled "Letters, Memoirs, and Negotiations of the Count d'Estrades." An improved edition was published in 1743 at the Hague, in 9 vols. 12mo.

ESTRANGEL, ESTRANGELUS, in the Syriac *Grammar*. Estrangel character, is a particular species, or form, of Syriac letter; serving as the majuscule letters in that language.

Abraham Echellenfis takes the estrangel character for the true ancient Chaldee characters; and it is certain the Abyssinians, who call themselves Chaldeans, still occasionally use the estrangel character, if we may credit Hottinger, in his *Theaur. Philol.* p. 286. Bishop Walton, in his *Prolegomena*, gives us an estrangel alphabet.

ESTRAPADE, in the *Manege*, is the defence of a horse that will not obey, but to get rid of his rider, rises much before, and while his forehead is yet in the air, yerks furiously with his hind legs, striking higher than his head was before; and during his countertime goes back rather than advances.

ESTRAY, or STRAY, signifies any tame beast, or sheep, oxen, swine, and horses, or swans, found within a lordship, and not owned by any man; in which case being cried, according to law, in the church, and two market-towns adjoining, if it be not claimed by the owner, within a year and a day, it becomes the lord's of the soil where found. If the owner claims it within the year and day, he must pay the charges of finding, keeping, and proclaiming; and he may seize it, without telling the marks, or proving his property, which may be done at the trial if contested. If the beast stray within the year to another lordship, the first lord cannot retake it. An estray must be fed and kept, uninjured, and without labour, till it is reclaimed, or the limited time expires.

ESTREAT, EXTRACTUM, in *Law*, is used for the true copy, or duplicate, of some original writing, especially of amercements, or penalties, set down in the rolls of a court, to be levied by the bailiff, or other officer, on every offender. Justices, commissioners, &c. are to deliver their estreats into the exchequer yearly, after Michaelmas; and fines to have writs, which shall be entered in the estreat, in order as they are entered in the chancery rolls, &c. stat. 5 Hen. III. stat. 5. 16 Edw. II. All forfeited recognizances are to be first estreated in the exchequer by sheriffs of counties; on which process issues to levy the same to the use of the king. Stat. 22 and 33 Car. II. cap. 22.

Sheriffs' estreats must be in two parts, indented and sealed by the sheriff, and two justices of peace; who are to view them, and one of them is to remain with the sheriff, and the other with the justices. Stat. 11 Hen. VII. c. 15. The estreats of fines, at the quarter-sessions, are to be made by the justices; and to be double, one of which is to be delivered to the sheriff by indenture. Stat. 14 R. II. c. 2. Fines, post-fines, forfeitures, &c. must be estreated into the exchequer twice a year, on pain of 50*l*. And officers are to deliver in their returns of estreats upon oath. Stat. 22 & 23 Car. II. c. 22. 4 and 5 W. & M. c. 24. It is the course of the court of B. R. to send the estreats into the exchequer twice a year, *viz.* on the last day of the two issuable terms; but in extraordinary cases there may be a rule to estreat them sooner. 1 Salk. 45.

ESTREATS, *Clerk of the*. See CLERK.

ESTREES, FRANCIS-ANNIBAL D', in *Biography*, was born in 1573, and educated for the church, in which he had the bishopric of Noyon conferred upon him by Henry IV. at a very early age. When he was only twenty-one he resigned his ecclesiastical preferment, on account of the death of his elder brother, and assumed the profession of arms, in which he became distinguished under the title of the marquis De Coevres. He was ambassador extraordinary to Switzerland and the princes of Italy, in 1614. He was created marshal of France in 1626, and in 1630 succoured the duke of Mantua, who was besieged in his capital. In 1636 he was deputed ambassador extraordinary to Rome, a character in which he well supported the honour and interests of his crown in opposition to pope Urban VIII., with whom, and the nephews of the haughty pontiff, he was continually involved in quarrels. He was recalled by his own sovereign, which he considered as an affront, and refused to appear at court, to give an account of his conduct. He died at Paris in 1670, at the great age of ninety-eight years, highly respected by his countrymen. At the desire of cardinal Richelieu, he drew up "Memoirs of the Regency of Mary de Medicis," which was published at Paris in 12mo. in the year 1660. "A relation of the Siege of Mantua, in 1620," and "An Account of the Conclave, in which Pope Gregory XV. was chosen in 1621," have also been given to the public from his papers. Moreri.

ESTREES, CÉSAR D', son of the preceding, was born in 1628, and being brought up to the church, he was raised to the bishopric of Laon in 1653. He was created cardinal by Clement X. in 1671; and at the death of that pontiff entered the conclave, and managed so as to put off the election five weeks, till the arrival of the other French cardinals. He was sent into Bavaria to negotiate the marriage of the dauphin in 1677, and afterwards went to Rome, on other important and difficult business. He supported the rights of the crown, and of the Gallican church in opposition to pope Innocent XI., whom he prevented from publishing any act infringing on both. He resided many years at Rome, the sole resident on the part of France, and exerted much influence at the election of succeeding popes. On his return to France he was rewarded with the rich abbey of St. Germain des Pres, where he died in 1714, in his eighty-seventh year, greatly regretted, &c. leaving behind him a high character as a politician. Moreri.

ESTREES-Saint-Denis, in *Geography*, a small town of France, in the department of the Oise, chief place of a canton, in the district of Compiègne, with a population of 1040 individuals. The canton has a territorial extent of 150 kilometres, with 20 communes, and 10,325 inhabitants.

ESTREMADURA, *i. e.* *Extrema Durii*, a province of

Portugal, bounded on the north by Beira, on the east and south by Beira and Alentejo, on the west by the ocean; lying between 38° and 40° N. lat. and obliquely between 7° 10' and 9° 30' W. long.; being 140 miles from north to south, and 70 in breadth; containing 5,440 square miles, 8 jurisdictions, 400 parishes, and 350,760 inhabitants. Several districts of this province are abundantly fertile, yielding grain, wine, oil, and fruits. The whole country is covered with flowers, and the bees produce a great quantity of honey. The manufacture of salt affords one of the chief articles of commerce. The principal towns are Lisbon, Leiria, Abrantes, Pombal, Alcobaca, Setuval, Thomar, Santarem, Alanquer, Torres Vedras, Cintra, and Cascaes; and the chief rivers are the Tagus, or Tajo, and the Sador or Sado, sometimes called Cadaon and Caldas.

ESTREMADURA, a province of Spain, bounded on the N. by Leon; on the E. by New Castile; on the S. by Andalusia; and on the W. by Portugal; lying between 38° and 40° N. lat.; and between 7° 10' and 4° 40' W. long.: being 140 miles from north to south, and 90 — 100 from west to east. This province was formerly a part of Portugal, but being separated from that country, it is sometimes called Estremadura of Castile. It is traversed by the rivers Guadiana and Tajo, which divide it into three equal parts. Intersected by ridges of hills, it abounds in grain, fruits, and excellent pastures; but good water is scarce, and the air in summer is exceedingly hot, insupportable to strangers, but to the natives not insalubrious. The principal commerce consists of cattle and fine wool; and the hills are covered with oaks, the acorns of which feed large herds of swine, that are black. The inhabitants are in general inclined to corpulency; and are considered as humane, affable, sincere, stout, and brave. The principal towns are Badajoz, Placentia, Coria, Albuquerque, Cáceres, Truxillo, Merida, Montejó, Xeres de los Cavalleros, Ellereña, and Zafra; and the chief rivers are the Guadiana, the Tajo, and the Alagon.

ESTREMERÁ, a town of Spain, in New Castile; 27 miles S.E. of Madrid.

ESTREMOZ, a fortified ill-built town of Portugal, in the province of Alentejo, containing three churches, six convents, two hospitals, and 6500 inhabitants; pleasantly situated on a rising ground in a fertile country; 7 leagues N.E. of the capital; and famous on account of a victory gained by the Portuguese over the Castilians, in the year 1663. In its vicinity there is excellent marble. The country on the west side of the town is pleasant and well cultivated, abounding in orange gardens and laurels; but at some distance no traces of cultivation appear. This town has a manufacture of beautiful earthenware.

ESTREPAGNI. See ETREPAGNY.

ESTREPEMENT, in *Law*, an impoverishing or making of land barren, by continual plowing and sowing, without due manuring, rest, and other husbandry.

The word is derived from the French *estropier*, to maim; or the Latin *extirpare*, to extirpate, root up.

ESTREPEMENT is also used for any waste, or spoil, made by the tenant for life, upon lands or woods, to the prejudice of him in reversion; as the cutting down of trees, or lopping them farther than the law allows, &c.

ESTREPEMENT is also a writ which lies in two cases: the one, by the stat. of Gloucester, 6 E. I. c. 13, when a man having an action depending, as a formedon, writ of right, or the like, sues to inhibit the tenant from making waste during the suit.

The other is for the demandant, who is adjudged to recover seisin of the land in question; and before execution,

for fear of waste to be made till he can get possession, sues out his writ.

**ESTRICH**, or **OESTRICH**, in *Geography*, a town of Germany, in the circle of the Lower Rhine, and electorate of Mentz on the Rhine; 14 miles W. of Mentz.

**ESTUCUA**, a town of Mexico, in the province of Mechoachan; 58 miles W. of Mechoachan.

**ESULA**, or **ÆSULUM**, in *Ancient Geography*, a town of Italy, situated on a mountain, near the Tiber.

**ESULA**, or *Æsula*, in *Botany*, a word said to be of Arabian origin. See **EUPHORBIA** *Esula*, and **APOCYNUM** *Venetum*.

**ESULÆ RADIX**, in the *Materia Medica*, the name of a root of a plant of the spurge kind, sometimes used in medicine. The root consisting of a cortical part, and an inner sticky one, the bark only is used; and such should be chosen as is new dried, and of a reddish colour without and within, and such as, when held in the mouth, affords a very disagreeable taste, with great acrimony. It is a very violent purge, and has been said to have performed cures in dropical cases, when more gentle medicines have proved ineffectual. It is a good method to macerate it a day or two in vinegar before it is used.

**ESURIS**, in *Ancient Geography*, a town of Spain, supposed to be *Xeres*.

**ESUS**, or **HESUS**, in *Mythology*, a deity among the Gauls, to which they sacrificed after victory whatsoever came alive into their possession. They sometimes sprinkled the altars of this deity with the blood of their women and children.

**ESZEK**, in *Geography*, a town of Slavonia, with a wooden bridge, built by the Turks over the Drave; 48 miles W.N.W. of Peter-Waradin, and 80 N.W. of Belgrade.

**ETABLES**, a town of France, in the department of the North Coasts, and district of St. Brieu; 2½ leagues N. of St. Brieu.

**ETAIN**, or **ESTAIN**, a small town of France, in the department of the Meuse, chief place of a canton in the district of Verdun, 18 miles N.E. of Verdun. It has a population of 2300 individuals, and its canton comprises 30 communes, with 7125 inhabitants, on a territorial extent of 247½ kilometres.

**ETALLE**, a small town of France, in the department of the Forêts, chief place of a canton in the district of Neufchâteau, with a population of 1080 individuals. Its canton has a territorial extent of 280 kilometres, and 13 communes, with 9013 inhabitants.

**ETAMPES**, a small town of France, in the department of Seine and Oise, chief place of a district of the same name, with a population of 7786 individuals. It is situated on the left bank of the river Juine, at the confluence of two other rivulets, 36 miles E. of Chartres; 45 miles N. by E. of Orleans; and 40 miles S. of Paris. N. lat. 48° 25'. The canton contains 14,187 inhabitants, dispersed in 15 communes, on a territorial extent of 192½ kilometres.

As chief place of a district, Etampes has a sub-prefect, a court of justice, and a register office. There are some manufactures of hosiery, woollen, and cotton yarn, and leather. The stockings, in particular, are known in the French trade by the name of stockings of Beauce, or Bas de Beauce, from the village where the best are made.

The soil of the district of Etampes is sandy: it produces, however, some wheat, rye, barley, oats, and hemp. There are a few vineyards and some artificial meadows. The district contains 6 cantons, 111 communes, 1372½ kilometres, and 58,890 inhabitants.

**ETANGS**, **LES**, a town of France, in the department of the Moselle, and district of Boulay; 2½ leagues E.N.E. of Metz.

**ETAPLES**, or **ESTAPLES**, a small town of France, in the department of the Pas de Calais, chief place of a canton in the district of Montreuil, with a population of 1360 individuals. It is situated at the mouth of the river Canche, which forms a small harbour, 12 miles N.E. of Boulogne, 168 miles N. of Paris. N. lat. 50° 30' 44". The canton contains 19 communes, and 7807 inhabitants, on a territorial extent of 232½ kilometres.

**ETAPPE**, in *War*, an allowance of provisions and forage made to the soldiers upon march through a kingdom, or province, to or from winter quarters.

Hence, he that contracts with the country, or territory, for furnishing the troops in their march, is called *etappier*.

**ETARRY**, in *Geography*, a town of Hindoostan, in the country of Bahar; 34 miles S.W. of Arrah.

**ETAULIERS**, a town of France, in the department of the Gironde, and district of Bourg; seven miles N. of Blaye.

**ETASAGGAH**, a town of Hindoostan, in Bahar; 35 miles S.E. of Bahar.

**ETAVERAM**, a town of Hindoostan, in the Carnatic; 10 miles E. of Coilpetta.

**ETAYA**, a circar of Hindoostan, in the Soubah of Agra, bounded on the N. by Rohilla; on the E. by the circar of Pattan, Canoge an Corah, and on the S.W. by Jumna. Etaya is the capital.

**ETAYA**, a town of Hindoostan, in the country of Agra, on the N.E. side of the Jumna, 52 miles S.E. of Agra. N. lat. 26° 45'. E. long. 79° 17'.

**ETCH**, in *Agriculture*, a term signifying the same thing as *ersh*. See **ERSH**.

**ETCHAUK**, in *Geography*, a town of Bengal, 22 miles N. of Ramgur.

**ETCHING**, in the *Polite Arts*, an important branch of that species of engraving which is performed with the view of delivering impressions on paper, by means of the rolling-press, is the superaddition of the chemical process of corrosion, to the art of drawing through etching-varnish, (or etching-ground, as it is more frequently termed,) on plates of metal; though it has sometimes been successfully performed on other substances, and particularly on glass.

Etching is most frequently performed on plates of copper; and (though aqua-tinta be a species of etching, for which see **AQUA-TINTA**) the means commonly employed, are lines drawn with a stylus, or steel-point, termed an etching-needle, which are afterwards corroded by aqua-fortis.

The etching-needle resembles the dry point (see the article **DRY-POINT**) in all respects, excepting the superior sharpness of the latter, and that it need not be quite so long as dry-points are at the first. Of these needles, the artist should provide himself with three or four, for etching finer or coarser lines, of various dimensions and different degrees of bluntness; that for the finest or most delicate lines being little less sharp than the dry-point. That he may with certainty etch lines of similar strength and depth, where such are required, as in covering a surface of an even tint, the extreme point of his needle should be very delicately and gradually rounded off on a leathern strop supplied with crocus-martis, or putty-powder.

The practitioner in etching should, moreover, provide himself with a soft and large camel's-hair brush, wherewith occasionally to sweep the dust, and erased etching ground, from the surface of his work: and an etching-board of from three to six inches in breadth, bevelled to an edge on one side, supported at the ends by small bars of wood about one-third of an inch in thickness, and of sufficient span to stand as a bridge over the varnished plate, and prevent the engraver's hand from touching and marring his work, should also be provided,

provided, and the copper-plate, being previously prepared, as see COPPER-PLATE, he may proceed to lay his etching-ground in the following manner.

The plate is put upon a German stove, or chafing-dish, and heated over the fire; or, if small, is held with a hand-vice, the polished side being upwards, and heated with the flame of paper burning under it; when hot, it is rubbed over with etching varnish (such as is described in the sequel of this article) wrapped up in taffety, which should be gently passed from one side to the other in a right line, so as to form several rows, till the plate is every where moderately covered; then with a *dabber*, formed of cotton, tied up in Persian silk, let every part of the plate be beat gently, while the varnish is in a fluid state; and in order to give it a fine grain, and that the varnish may be equally spread over the surface of the plate, continue to beat it with the dabber, after the plate is taken from the fire; till it attains a somewhat harder consistence in cooling; but the use of the dabber should be discontinued long before the varnish is cold, lest it should be made to rise from the plate.

When the plate is thus uniformly and thinly covered with the varnish, it must be blackened whilst it is yet warm by a piece of flambeau, or of a large wax-candle, or taper, twitted together, till six or more flames unite in one, which affords a copious smoke; dispatch is of importance, that the varnish may not grow cold during the operation, which should be performed, if possible, at one heating of the plate, for repeated melting of the varnish does it much damage. Large plates may be suspended from the ceiling of a room by four cords and iron rings, with the varnished side downwards, for the greater convenience of being blackened. Care should be taken that the flambeau or candles be kept at a proper distance from the plate, that the wick may not touch and burn, or otherwise impair the varnish. The varnish may be made white, if that colour is preferred to black, by grinding white lead in water, and putting it into a glazed earthen dish, with a little good glue dissolved, and melting the whole together. This mixture is spread with a brush or pencil of hog's hairs thinly and evenly on the varnish laid on the plate and smoothed. The colour is then left to dry; if it fixes with difficulty on the varnish, the composition should be mixed with a drop or two of ox-gall.

When the copper-plate is thus varnished, and is quite cold, it remains to transfer from paper to the varnished plate, the tracing, or outline of the design. If the outline be reduced from an oil or water-colour picture or other original of larger dimensions than the intended etching, and be executed with lead pencil or red chalk upon drawing or writing paper, the method most in use among English engravers, is, to take the varnished plate and outline to the rolling-press printers, and (suffering the latter to lie between wetted paper for a quarter of an hour or so, that it may become sufficiently damp for the lead or chalk to be in a certain degree liquified, while the paper is sufficiently softened to do no injury to the etching ground,) to pass it through the press, the upper roller thereof being supplied with blankets in the same quantity, and the press adjusted to about the same degree of pressure, as for printing. If this be carefully performed, the outline will appear at once transferred, and reversed on to, the surface of the etching-ground, and the artist have nothing to do but to proceed with his etching. By these means the trouble both of retracing and *reversing* (*i. e.* of changing the right hand view of his picture round to the left, and *vice versa*, the left to the right, as it would appear if reflected in a looking-glass,) is saved to the engraver. The method formerly used,—which must ever be used where no rolling press is at hand,

and which is still believed to be generally practised in the other countries of Europe—is, either to trace the outline of the design on transparent paper, that by simply turning the paper it may be seen in reverse, or using thin drawing paper for the purpose, to render it transparent afterwards by means of oil or varnish. When this is thoroughly dry, a piece of fan, or other very thin, paper, of the size of the outline to be traced, must be evenly rubbed over on one side with powdered red chalk or black lead, and interposed between the outline and varnished plate, with the chalked or leaded side downward, and both outline and tracing paper being stretched tight over the varnished plate, and fastened by means of small bits of wax placed along the margin, a blunt etching-needle must be carefully passed over the several outlines with a moderate degree of pressure, which will occasion so much of the powdered lead or chalk to adhere to the smoked etching ground, as, when the papers are removed, will exhibit the outline or tracing of the whole design in all its correctness.

Having proceeded through these introductory mechanical preparations, which require care and some knowledge of drawing, the engraver's task as an artist, or man of taste or genius, properly begins. Who shall prescribe laws to genius?—He may now exercise the knowledge he has previously stored, and call forth his inventive powers. The forms of his objects must now be severally drawn, with such taste and feeling as he may possess; and his shadows, demitints, and lights, excepting such as he may prefer to leave to be executed by the graver or dry point, be hatched, by employing lines more close or more open, and pressing on his needles more lightly or more strongly, as a skilful musician presses on the keys of his harpsichord, and as the several parts of his work may demand, varying his line with the nature of his object.

The characteristic, or local advantage of etching, for certain purposes, over lines cut with the graver, consists in the unlimited freedom of which this mode of art is susceptible. The etching-needle, meeting little resistance from the varnish, glides along the surface of the plate, and easily takes any turn that the taste of the artist may direct, or his hand accomplish; and hence its peculiar adaptation to the expression of that class of objects which artists term *picturelike*, such as trees, rocks, ruins, cottages, the shaggy hair of animals, broken ground, or other rough and irregular surfaces.

It has formerly been much disputed among the curious, whether Germany or Italy had the honour of giving birth to the invention of etching, and with the view of ascertaining this point, the dates of the impressions from the earliest etchings by Albert Durer and Parmegiano have been assiduously sought for and compared. The writer of the present article conceives that some portion, at least, of this discussion and research, might have been spared, had the disputants reflected that etching, originally *Etzen*, is not an Italian but a German word, and how very unlikely it is that an Italian invention should have been denominated by a German word.

Although this art afforded means analogous to the objects themselves, of drawing and characterising all those objects, of which wildness and freedom, communicated by spontaneous perception and feeling, is the soul, yet engraving with the graver had been previously invented, and in the beginning of the sixteenth century impressions from such engravings had called forth the admiration of the tasteful. For these reasons, and from the prevalence of those habits, and prejudices of taste and education, which hang like dark veils about the faculties of man, the extent and variety of energy of which etching was capable were not perceived,

and probably are not even yet perceived; the means of engraving, or manual operation of the graver, was mistaken for the end; and hence a false criterion of merit obtained considerable influence; connoisseurs gravely put on their critical spectacles in order to see in what degree, and how dexterously, the etcher had imitated the clear and clean-cut lines of the graver; just as the early printers with the letter press, merely endeavoured to imitate M.S. missals and bibles, without perceiving the superior degree of perfection of which printing was susceptible. The Saddlers, Le Bosse, and others run into this egregious mistake, and the latter, who wrote a treatise on the art of engraving, lays it down as a principle, that the perfection of this mode of engraving consists in the close similitude of etching to the work done by the graving-tool.

That the efforts of the most tasteful, bold, and inventive among the engravers of our own country, have largely contributed to dispel these prejudices, will be seen towards the close of this article. At present we proceed with our account of the process of etching.

The forms of the several objects of which any given etching may consist, being drawn with requisite knowledge and care, and the chiaroscuro, and expression of the textures of the several substances introduced into the composition, hatched with the degrees of taste and truth, which the ability of the artist may enable him to display, the business of corrosion, which is technically called *Biting-in*, begins. For this purpose a border of such wax as is of a moderate degree of hardness when cold, and of a moderate degree of tenacity whilst warm, must be applied round the margin of the plate, in the form of a little wall or rampart, about an inch, or three quarters of an inch in height. This wax may be composed of bees' wax, either tempered with common pitch, or with Venice turpentine and tallow, and at one of the corners a gutter, or spout, should be formed for pouring the aquafortis conveniently off the plate. The plate being thus bordered, it is usual further to fortify or secure the work against the egress of the aquafortis whilst biting, by turpentine-varnish thickened with lamp-black, and applied with a hair pencil on the margin of the plate, and under the inside edge of the rampart of wax. This varnish or composition (which is called *stop-ground*) being sufficiently dry, the aquafortis may be poured on the plate.

We are now arrived at a part of the process where experience, combined with chemical knowledge, is the only practical guide on which any thing like sound reliance may be placed. Yet a few general rules may not be dispensed with. The aquafortis may either be pure nitrous acid, diluted with pure water in the proportions of four or five parts water to one of nitrous acid for the more delicate parts of the etching, or it may be the double aquafortis of the shops diluted with pure water in the proportions of two to one, or sometimes of equal parts, according to the degree of strength or delicacy of the faintest parts of the work. Of aquafortis thus diluted, but which must be gradually strengthened as the work proceeds, let a sufficient quantity be employed to rise, when poured on the plate, about half an inch above its surface. If all things have been rightly conducted, it will now be seen that the menstruum will soon exert its action in those lines or hatches where the artist has pressed hardest on his etching-needle, and will gradually begin to corrode the more delicate lines. It may here be proper to observe that a feather, or camel's hair brush, should be used during the biting, to burst the small bubbles of fixed air which are liberated from the copper, and cleanse away from the lines the verdigrise which is generated during the operation of the aquafortis: by thus moving the

aquafortis to and fro on the plate, it will exert its action uniformly over the whole etching.

In about a quarter of an hour, or when the effects of the aquafortis have become visible in the more tender parts, it may be poured off, the plate washed with clean water, and dried by exposure to the air, sunshine, or (which is now more common, because more expeditious) by the operation of a pair of bellows. After trial made by taking off a small portion of the etching-ground with the scraper, or a small piece of pointed charcoal, such parts of the etching as are believed to be sufficiently corroded, must be painted over carefully, or *stopped-out*, with the composition of lamp-black and turpentine varnish which is mentioned above; and when this is dry, the aquafortis must be re-applied, and the biting proceeded with in the same manner, till the stronger parts are judged to be sufficiently corroded, the aquafortis being strengthened from time to time according to the judgment of the operator.

To bite-in a large plate will sometimes occupy several days, for great judgment and nicety of observation are required in gradating the chiaroscuro, and considerable care must be exerted in the stopping-out. It need scarcely be mentioned, that the operator should be as cautious as the necessary degree of attention to his work will allow, not to inhale the fumes which arise from the mingled copper and aquafortis, which become more and more deleterious, as the biting advances.

When the strongest parts are believed to be sufficiently corroded, and the plate is thoroughly washed with water, it may be again placed on the chafing dish, or German stove, till it be sufficiently warm for the border of wax to be removed, after which, and while it is yet warm, the varnish may be diluted by the application of a small quantity of oil of turpentine or of olives, and wiped off with a rag; when, if the biting-in hath been successfully accomplished, the etching is complete, and in some cases the plate is finished; though in most cases it happens that the engraver's taste and judgment direct him purposely to leave certain parts to be finished with the dry point and graver.

For an account of the early progress of the art of etching, the reader is referred to our account of the GERMAN and ITALIAN schools of engraving. Its more recent improvements have taken place in England. In etching trees, which no other mode of engraving can adequately express, Vivares and Pouncy have displayed an art of characterizing the species of tree which it was their object to represent, and at the same time of suggesting in the varying styles of their foliage, those masses or countless numbers of leaves which are seen in nature itself. Their etchings of trees are decidedly superior to those which have been produced on the continent, unless we might except the trees of Waterloo and Kobell, and have rarely been equalled by those of the engravers of our own island.

He who would see the most perfect specimens which have been produced of this species of art, should look at aquafortis proofs (not the finished engravings) which Vivares has produced after Claude, Patel, and Gainsborough; and those which Pouncy has etched after Wilson, Hearne, and Farington. In looking at the former, he will see with surprise how much Vivares has attained of the peculiar beauty, feeling, and delicacy of Claude's pencil, although he could only have been acquainted with certain pictures:—the larger Colonna Claude for example, from which he has produced a most exquisite etching—through the medium of chalk drawings, and those not very good. It is not less worthy of admiration, at least of high approbation, to observe how truly Pouncy has characterized the painting of Wilson, in

## ETCHING.

his etchings of "Athens in Prosperity," and "Athens in Ruin," which are also executed from chalk drawings copied from the originals of Wilson in the library of the late Mr. Willett.

In rocks and cottage subjects Browne has scarcely been less successful, as may be seen in the aquafortis proofs of the best of his large plates after Both, Salvator Rosa, and Du Sart. In the rocks of his "St. John preaching," after Salvator Rosa, he is perhaps somewhat extravagant, and out of harmony with his own figures and foliage, though vigorous and characteristically rugged; but in "the Cottagers," and "the Jocund Peasants," after Du Sart, he is unrivalled; the several textures of the old plaster walls, old planks, thatch, broken ground, rough coated animals, (though these are probably etched by Woollett,) and even the flush which trickles down the hog-trough, are etched with the truest feeling of nature and Du Sart.

In etching ruins, as well as more perfect architectural subjects, Piranesi the Roman led the way, and Rooker the elder successfully followed. These artists more than perhaps any other, except Mr. Lowry, shewed the affinity, or susceptibility of picturesque union, which subsists in fine art, between freedom of handling and geometrical precision; as may be seen with pleasure in the antiquities of Rome and Pæstum, which Piranesi etched from his own drawings; (the original and very masterly drawings of the temples at Pæstum being preserved in the collection of Mr. C. Lambert of the Temple F. A. S.) in the six large views of London, which Rooker etched after the drawings of P. Sandby and himself; and among numerous other works from the hand of Mr. Lowry, in the plate of the west door of the cathedral of Carrara from the drawing of Flaxman, as well as in various other plates of architectural and mechanical subjects, by which this work is illustrated and adorned, and which consist almost entirely of etching.

With the view of etching subjects of this kind with superior accuracy and facility, Mr. Lowry, about twenty years since, invented and began to construct several instruments or machines, which it is within the knowledge of the writer of this article have been much employed on the engravings which are spoken of above. The first was "for etching successive lines either equidistant, or in just graduation from being wide apart to the nearest approximation, *ad infinitum*; the compass of the instrument being commensurate with the possible demands of the art. The second, which is more recently constructed, is for striking elliptical, parabolical, and hyperbolical curves, and, in general, all those lines which geometricians call mechanical curves, from the dimensions of the point of a needle, to an extent of five feet."

Within the last seven years he has constructed other machinery for facilitating particular operations in etching, and ensuring precision in describing arches of circles of every possible radius; lines converging to points at all distances; various kinds of spiral lines, and the cogs and smaller teeth of wheel work; of the several uses and superior powers of which machinery, numerous examples may be seen in what has already appeared of this Cyclopædia.

Of these inventions it may be truly said that they combine elegance with utility, and are of high value if only considered as auxiliaries of the imitative part of this branch of engraving; but as the auxiliaries of chemical, agricultural, and mechanical science, they are of incalculable advantage. The accuracy of their operation, as far as human sense, aided by the magnifying powers of glasses, enables us to say so, is perfect; and it is not necessary here to insist on the advantages that must result to the whole cycle of science,

from mathematical accuracy. A hope may be indulged that before the completion of these volumes, Mr. Lowry may be induced to favour the public with plates, and particular descriptions of his various apparatus.

It now remains to describe the composition of the several kinds of etching-ground, which have been used by different engravers from time to time.

Of etching grounds there are three principal kinds, *viz.* common etching ground, hard ground, and soft ground.

The hard ground was formerly much used, being better accommodated to the intention of imitating the engraving with the tool; but the former has now wholly superseded the use of the other, as it gives a power of expression incompatible with the greater inflexibility of the hard varnish, which confines the lines and hatches to such a sameness and regularity as give a stiffness of manner, and coldness of effect to the work.

There are various directions for preparing the common etching-varnish, which is by far the most in use and the most worthy of being so. Le Bosse recommends the following: take of virgin wax, very white and clean, and of grains of mastic very clear and pure, each one ounce; and of calcined asphaltum, half an ounce: grind the mastic and asphaltum separately, very small, and melt the wax over the fire in an earthen pot well glazed. When the wax is thoroughly melted, and very hot, sprinkle the mastic into it gradually that it may melt, and stir the mixture that the ingredients may incorporate. Then sprinkle the asphaltum into the mixture, stirring the whole composition over the fire till the asphaltum be entirely melted: take the pot from the fire, and let the mixture cool; and pour the varnish into clean warm water, and by working it with the hand, form it into a roll of about an inch in diameter, or into small balls, which may be wrapt up in taffety and kept for use. The quantity of wax should be increased in winter, in order to temper the varnish to the existing state of the atmosphere.

The following varnish is used by many of the engravers at Paris: take of virgin wax, and asphaltum, of each one ounce; half an ounce of black pitch; and a quarter of an ounce of Burgundy pitch: the asphaltum must be pounded in a mortar, and the wax melted over a slow fire in a pot of glazed earthen-ware, and the rest of the ingredients added by little and little, stirring the mixture till the whole be well melted and incorporated. Then throw the whole mass into a vessel of clean warm water, and proceed as before.

Mr. Lowry's recipe for common etching ground is as follows:—To two ounces of asphaltum add one of Burgundy-pitch, and an ounce and a half of white virgin wax. The asphaltum must first be finely powdered, and then melted in the glazed earthen vessel over a moderate fire, before the Burgundy pitch is put in: the wax must be added last, when the whole composition must be well stirred, and then poured into warm water, to be further incorporated by means of the hands, and made up into balls for use.

The *hard* varnish, which was used by Callott and other engravers of the continent, and which was commonly called the Florence varnish, was prepared in the following manner. Take four ounces of fat oil, very clear, and made of good linseed oil, like that used by painters. Heat it in a new pot of glazed earthen ware, and afterward put to it four ounces of grains of mastic well powdered, and stir the mixture briskly till the whole be well melted together, then filter the whole through a piece of fine linen into a glass bottle with a long neck, that can be stopt very securely, and keep it for use.

In laying this varnish on the plate, it may be spread evenly with the dabber and smoked, as before directed, but after

## ETCHING.

after it is so spread, there remains to dry or harden it over the fire, for which purpose it will be proper to prepare a charcoal fire which shall emit no sparks; it should be contained in a coal-pan or chafing-dish, somewhat larger than the plate, which should be placed over it for the space of from eight to twelve minutes, every precaution being used to prevent dust from approaching the plate. Whilst in this situation the varnish will soon begin to smoke, and when this smoking is observed to decrease, the plate must be removed from the fire, and touched at the side or on the margin with a little piece of hard wood. If the varnish be easily raised by the touch, it is yet too soft, and the plate must be again placed over the fire as before: after a short time it must again be tried with the stick, and if the stick adhere to the varnish so as to require some slight effort to draw it away, the plate must from that instant be left to cool. If on the first trial the stick adhere strongly to the varnish, water must be immediately thrown on the back of the plate, to cool it as quickly as possible, lest a longer continuance of the heat render it too hard, or burn the varnish. When the plate is cold, the artist may proceed with the tracing and etching, as before directed.

The *soft* ground or varnish is prepared simply by mixing common etching ground with animal oil, in proportion of more or less according to the existing state of the atmosphere; a much smaller portion of the oleaginous ingredient being admissible in summer than in winter. If common tallow be used for the purpose, the salt which it may contain should first be precipitated, by dropping the melted tallow into water, and afterward skimming it from the top; but Mr. Gilpin recommends veal suet, and it is probably to be preferred.

The method of using soft ground is as follows. Over a plate thinly covered with this sort of varnish, and smoked as in the case of the common etching ground, the artist cautiously spreads a sheet of very thin paper, which it is best to spread in a damp state, and to fasten with strong paste by the edges, which should be folded over for the purpose on the back of the plate: the paper will thus, when dry, be stretched tight and flat over the surface of the varnish.

All is now ready for the reception of the etching, which is performed simply by making a hatched drawing of the intended subject with a black lead pencil on this paper. Great care must be taken during the etching that nothing but the pencil touch the paper, and for this purpose such a bridge must be employed on which to rest the hand of the artist, as is before recommended. When the drawing is complete, the paper must be carefully removed from the surface of the plate, which must be surrounded with a rampart of wax, and the aquafortis applied as before directed. This is the whole of the process of etching in soft ground. As much of the varnish as it was necessary to remove, in order to admit the aquafortis to the copper, will be found to have adhered to the back of the paper on which the artist has been drawing, which, presuming the plate to be judiciously *bit-in*, will exhibit the exact archetype of the impressions which the etchings will produce.

It remains to be said of etching in soft ground, that the slipping with the graver, which it is sometimes found necessary to add in certain parts, after the plate is *bit-in*, does not incorporate so thoroughly with the sketchy looseness and chalky texture of the etching, but that a judicious eye will always discover the junction, and a delicate taste will dwell on it with the same kind of dissatisfaction that we regard a modern repair of a fine old picture that has been damaged; and further, that though it be a mode of art extremely well

calculated to imitate a painter's sketch or drawing in black-lead or chalk, it is by no means capable of producing a complete abstract of a finished picture.

There are certain local energies peculiar to every branch of engraving. He who should endeavour in mezzotinto or the chalk manner to rival the playful freedom and characteristic taste which is displayed by Vivares in his etchings of trees, would find himself as much mistaken in his aims as he who by etching through soft ground, or on *stone* for which see *ETCHING on Stone*,) should attempt to render the delicate blandishments, so as to produce a complete abstract of the full harmony, of the finished works of Correggio or Claude. On the other hand, either of these modes of etching is far more capable of producing a faithful transcript of a drawing hatched with chalk or lead-pencil, than the powers of the graver and aquafortis united on copper, and of multiplying such drawings, certainly affords the most efficient means.

It may not be superfluous to add that it is not the painter's sketches that it is most desirable to multiply, but his finished performances; we wish most to see the mercury of his active imagination amalgamated with the sterling gold of his cultivated understanding; and we justly value an art of engraving as it is capable of rendering or reproducing the pure forms into which this rich mass may be moulded.

*ETCHING on Stone.* A method of etching on calcareous substances, which may be termed a chemical art of multiplying hatched drawings, has also been recently discovered in England, or recently imported from Germany; and some very spirited sketchy etchings have been executed in this way by the president West, and Messrs Fufeli, Cofway, Barry, and some other members of the Royal Academy. Messrs. Corbould, Stubbs, and C. Heath are also among those who have successfully practised this new art.

The materials were supplied by a gentleman not now in England: the knowledge of the exact proportions of the ingredients of which they consisted, was not imparted to those who made use of them, neither is it believed to have been imparted to any one else; but the materials themselves being known, the proportions may presumptively be ascertained by a little experience.

The stone was of a species resembling that fine-grained stone of a yellowish colour, which is found in large quantities in the neighbourhood of Bath, and is called Bath stone. The etchings were of two kinds; those performed with a crayon, and those performed with pen and ink. The crayon was a mixture of white wax and lamp-black, with a small quantity of shell-lac. The ink consisted of shell-lac, borax, and water, and the stones which received the crayons were ground to a surface somewhat less smooth than those which were prepared for the reception of the ink.

The method of etching is merely *drawing* on the stone with these materials. The mystery, or secret—which any chemist would easily develop—resides in the manner of printing these drawings, and is simply as follows.

The ink is to be prepared as printer's ink is commonly prepared, namely, ground up with oil, and the paper which is to receive the impression must be damped in the usual manner. The etched stone is then to be wetted by immersion in water; when it is taken out, and while it is still wet, the ink being carefully applied on its surface, without violent friction, by means of a printer's ball (such as is used in letter-press printing) will be found to adhere only where the stone has been hatched by the artist, with the crayon or ink, the antipathy of oil to water effectually preventing it from sticking any where else. The paper is now to be placed as in letter-press printing, and a pressure, which need not be very violent,

violent, applied either by means of a roller passed over the back of the paper or otherwise: a blanket or finer woollen cloth, being interposed between the roller and paper.

**ETCHING on Glass**, is performed in the following manner: Lay a thin coat of white wax (as etching ground is laid) on the plate of glass. On this the drawing must be traced in the usual way. When the subject is etched, a border or wall of wax of a very even height must be put around: take then some flour spar powdered to about the fineness of oatmeal, and strew it *evenly* over the etching, and on this pour a mixture of equal quantities of sulphuric acid and water, till the whole is about the consistence of thick cream: a cover of metal or wood must then be laid over, and fitted close on the border of wax, to keep in the fumes of the acid, the escape of which would so weaken the liquor that it would not act on the glass, and would besides be very hurtful to the lungs.

If the subject be to be etched with care, and high finishing be required, the acid mixture must be taken off occasionally, and the plate, after being well washed and dried, must have the parts that are bit-in enough, stopped-out, as in common etchings, when the mixture must be again put on, and closed down as before; and this must be repeated till the several gradations of shade are believed to be sufficiently corroded.

Etchings on glass are printed by means of the rolling press, and it need scarcely be added that much care is requisite on the part of the printer, lest the plates of glass should split in passing through the press.

**ETEA**, or **ΕΤΙΑ**, in *Ancient Geography*, a small town of the isle of Crete.

**ETELANT**, in *Geography*, a town of Asiatic Turkey, in the Arabian Irak, situated on the Tigris; 66 miles N.N.W. of Bassora.

**ETENDUE**, *Fr.* in *Music*. See **COMPASS**.

**ETEON**, in *Ancient Geography*, a town of Greece, in Bœotia.

**ETEONOS**, a town of Greece, in Eubœa.

**ETERNAL FLOWER**, in *Botany*. See **XERANTHEMUM**.

**ETERNITY**, duration which is conceived incommensurable with time, and exclusive of beginning, progress, ending, &c. See **GOD**.

Authors are much at a loss for a proper and just definition of eternity: that of Boethius, *De Consol. Philos.* lib. v. part 6. *viz.* "Interminabilis vitæ tota simul et perfecta possessio, *i. e.* a perfect possession of a whole endless existence altogether," though retained by S. Thomas and others, is faulty in divers respects.

Censorinus, *De Die Natal.* defines eternity by infinite duration, that is, duration which has always been, and always will be. Others more fully describe it by a duration that exists altogether without any flux or succession of parts prior or posterior to each other: where the word duration, taken abstractedly, imports no more than the perseverance of a thing in its existence, the *τὸ durare* being here opposed to the *τὸ cessare, in existendo*.

But soften the word duration how you will, it is scarcely conceivable but by conceiving a quantity thereof, nor a quantity without conceiving a succession. Others, therefore, define eternity by a *perpetuum nunc*, a perpetual now; or a *nunc semper stans*, an everstanding now; but neither are these unexceptionable, the words *perpetuum* and *semper stans* importing an obscure sort of duration. See **DURATION**.

**ETERNITY**, in *Mythology*, a divinity among the Romans, who had neither temples nor altars. They represented it

under the figure of a woman, who held the sun in one hand and the moon in the other: her symbols were a phoenix, globe, and elephant.

**ETERNOZ**, in *Geography*, a town of France, in the department of Doubs, and district of Quingey;  $2\frac{1}{2}$  leagues S.E. of Quingey.

**ETESIAE**, or **ETESIAN Winds**, are such as blow at stated times of the year, from what part soever of the compass they come. They are so called from the Greek word *ετης*, year, being yearly or anniversary winds, such as our seamen call monsoons and trade-winds, which, in some parts of the world, continue constantly blowing for certain stated seasons of the year. Thus the north winds, which, during the dog-days, constantly blow upon the coasts of Egypt, and hinder all ships from sailing out of Alexandria for that season, are called etesie in Cæsar's Commentaries. In other authors, the west and east winds are called etesie, when they continue blowing for certain seasons of the year. Vide Salmast. *Exercit. in Solin.* p. 421.

Cellarius endeavours to prove that those winds are properly etesian which blow from that part of the horizon which is between the north and west about the time of the solstice. *Geog. Antiq. lib. i. cap. 8.* See **MONSOON** and **WIND**.

**ETETA**, in *Ancient Geography*, a town of Upper Mysia, according to Ptolemy; called *Ægeta* in the Itinerary of Antonine.

**ETFU**, or **ΕΤΦΟΥ**, in *Geography*, a village of Upper Egypt, situated near the Nile, above Esneh, built on the ruins of the great city of Apollo, or Apollinopolis Magna, and now governed by an Arab scheik. It possesses an ancient temple, covered with hieroglyphics, among which, says Savary, we distinguish men with falcons' heads. Its inhabitants were enemies of the crocodile. The extent, majesty, and preservation of this edifice, says Denon, who has given a view of it, "surpassed all that I had seen in Egypt, or elsewhere; it made an impression on me as vast as its own gigantic dimensions. This building is a long suite of pyramidal gates, of courts decorated with galleries, of porticoes, and of covered naves, constructed, not with common stones, but entire rocks." "The excellent preservation of this ancient edifice forms a wonderful contrast with the grey ruins of modern habitations built within its vast inclosure; a part of the population of this village is contained in huts built in the courts, and around the fragments of the temple; which, like swallows' nests in our houses, defile them without concealing or injuring their general appearance." Below Etfu, the cultivated country becomes very narrow, so that there is only a quarter of a league in breadth between the desert and the river.

**ETHAM**, in *Ancient Geography*, a town of Egypt, situated in the desert, which gave name to the lower part of the Red sea, opposite to Magdalum. It was the third station of the Israelites in their escape from Egypt.

**ETHELBERT**, in *Biography*, king of Kent, succeeded to the throne about the year 560. He began his reign with a resolution to revive the reputation of his family, which had been sinking in the scale of monarchy; with this view he made war upon the king of Wessex, by whom he was twice defeated, though he was afterwards triumphant, and acquired the complete ascendancy over Wessex and the other states, except Northumberland, and reduced them to the condition of his tributaries or dependants. In the reign of Ethelbert, Christianity was introduced into England. The king had married Bertha, daughter of the king of Paris, who being a Christian, had stipulated for the free exercise

exercise of her religion, and had carried over in her train a French bishop. So exemplary in every respect were her life and conduct, that she inspired the king and his court with a high respect for her person, and for the religion by which she appeared to be influenced. The pope, taking advantage of this circumstance, sent a mission of forty monks, at the head of whom was Augustine, to preach the gospel in the island. They landed in Kent in 597, and were well and hospitably received by Ethelbert, who assigned them habitations in the isle of Thanet. A conference was held, and the king took time to consider of the new doctrines propounded to him; and in the mean while gave them full liberty to preach to his subjects. Numbers were converted, and at length the king submitted to a public baptism, Christianity proved the means of promoting knowledge and civilization in this island; and the king, with the consent of his states, enacted a body of laws, which was the first written code promulgated by the northern conquerors. Ethelbert died in the year 616, and left his crown, after a reign of 50 years, to his son Edbald. Hume's Hist. of Eng.

**ETHELBERT**, king of England, was son of Ethelwolf, and succeeded to the government of the eastern part of the kingdom in 857, and in three years afterwards he became sole king. He died in 866, but had, in the course of his reign, shewn a considerable share of vigour in defending his dominions from the inroads of the Danes, who at that period were cruel enemies to this country, and continued to ravage one part as they were repulsed from another. Hume.

**ETHELEUM**, in *Geography*, a river of Asia, which separated between the Troade and Mysia.

**ETHELING**, or **ÆTHELING**. See **ÆTHELING**.

**ETHELRED I.**, in *Biography*, king of England, son of Ethelwolf, succeeded his brother in the year 866. The reign of this monarch was short but full of troubles. The Danes had already gained an ascendancy over the kingdom, and seemed now to threaten it with entire conquest. The enterprising Alfred united his skill to the power which his brother the king was able to call forth; they pursued the invaders from place to place, and drove them from the centre of Mercia. The Mercians, careless of their liberties, or jealous of the superiority which victory was likely to give to the monarch, refused to co-operate with him, and Ethelred was under the necessity of opposing the Danes with his West Saxons alone. With these he was generally successful, till large reinforcements were sent to support the invaders, which enabled them to make a stand against the natives. The actions fought were frequently very bloody, and in one of them Ethelred was wounded. He died in 871, leaving his crown to the immortal Alfred; of whom we have already spoken. Hume's Hist.

**ETHELRED II.** king of England, was son of Edgar, and brother to Edward the Martyr, whom he succeeded to the crown in the year 978. He was at this period a minor, and from his want of capacity and vigour in the affairs of government he was, in his riper years, characterized by the epithet of "The Unready." No man, however, stood more in need of exertion and enterprise, for the Danes, who had for several years forborne all depredations, renewed their attacks with the utmost fury; and meeting with little opposition, they became more bold, till, at length, in the year 993, under Sweyn king of Denmark, and Olave king of Norway, they made a formal invasion of the country. At first nothing seemed to oppose the rapidity of their progress: and they laid siege to London, which was valiantly and successfully defended by the citizens. A mistaken policy in behalf of the English induced them to purchase the departure of the invaders, who, in 997 and

998; returned in large bodies, laid waste the southern parts of the kingdom, and demanded a still larger bribe than they had before received. To strengthen himself by a foreign connection, Ethelred married, in 1001, Emma, sister to Richard II. duke of Normandy. In the following year a dreadful massacre took place, on the same day throughout England, of all the Danes settled in the kingdom. The English in this instance were the willing instruments in the hands of the king to execute his bloody orders. They spared neither age nor sex; even a sister of the Danish sovereign, who had married an earl, and had conformed to the Christian profession, was barbarously murdered, having already witnessed the death of her husband and infant children. Such revenge, says the historian, added nothing to the strength of the nation, but rendered its enemies more implacable. In 1003, Sweyn again invaded the island, and carried desolation all along the Western coast. On a subsequent occasion the bold invader obliged the nobles to swear allegiance to him as king of England, while Ethelred, in 1013, fled into Normandy with his family. Sweyn maintained his power only a year, when death put an end to his reign, and Ethelred was recalled by his loyal subjects. He resumed the government, but had not learned that wisdom which his misfortunes were calculated to teach; he submitted to Canute the son of Sweyn, whose valour and activity he was unable to resist. Ethelred died in 1016, after an inglorious reign of thirty-five years. Hume.

**ETHELWOLF**, king of England, succeeded his father Egbert in the year 838. Little ambitious of government, one of his first acts was to give his eldest son, Athelstan, the sovereignty over Essex, Kent, and Suffex. His whole reign was molested by the incursions of the Danes, and about the year 851 they became so formidable as to threaten the total subversion of the government. The natives were not inactive, but opposed the enemy with the utmost vigour; nevertheless they took up their winter-quarters in England, and before they returned, burnt Canterbury and London. In the midst of these dangers the king, excited by a spirit of devotion, made a pilgrimage to Rome, where he remained about a year, being accompanied by Alfred, who was afterwards king. During his absence he left his eldest son Athelstan as regent, who soon after died, and thus afforded an opportunity to his ambitious brother of seizing the reins of government with an intention of dethroning his father. To avoid the evil consequences of civil war the king, without hesitation, ceded the western part of his dominions to his son. After this, influenced, in all probability, by the intriguing monks, he summoned the estates of the whole kingdom, and solemnly conferred upon the clergy the tithes of all the produce of the lands. This act of piety, as it was denominated, was considered as the most effectual measure for resisting the Danes. Ethelwolf died in 857. Hume.

**ETHER**, in *Chemistry*, is a light, odorant, inflammable liquid, produced by the action of certain of the acids upon alcohol. The acids that have actually been employed for this purpose are the sulphuric, the nitric, the muriatic, the acetic, and the stœoric; whence originate as many species, or perhaps varieties of ether, all of which we shall describe in due order.

§ 1. *Sulphuric ether*.—The method of preparing this substance is first mentioned in the Dispensatory of Valerius Cordus, published about the year 1540; it was also known to Basil Valentine, Paracelsus, and Boyle: it had, however, attracted the notice of chemists only in a very imperfect degree, before it was described by Froben, a German, in the

Philosophical

Philosophical Transactions for 1730. Since that period the preparation and properties of sulphuric ether have been carefully investigated by many able chemists, especially Scheele, Dollfus, Macquer, Pelletier, Vauquelin and Fourcroy.

The mode of obtaining ether in the small way is as follows. Take a tubulated glass retort, of the capacity of about six quarts, lengthen its beak by an adopter, and pass the other end of the adopter into a two-neck quilled balloon receiver; fix another adopter into the opposite neck of the Balloon, and join to this a common quilled balloon receiver, placed in such a position that the quill, instead of pointing directly downwards, as in the first receiver, shall slant gently upwards; then lute all the junctures with linseed meal or common paste, except that of the retort to the first adopter; fix also a 24 ounce vial to the quill of the first receiver, and loosely close the quill of the second with a cork or plug of moist paper. The lute being moderately dry and hard, withdraw the retort, and pour in through the tubulure 40 ounces by weight of rectified alcohol, and 32 ounces of the strongest sulphuric acid. Replace the retort with its contents, being careful to shake it as little as possible, and let it remain for 12 hours or more, during which the acid and alcohol will gradually act on each other, producing a considerable degree of heat. Afterwards withdraw the retort, and mix together its contents as accurately as possible, by communicating to them a gentle circular motion; this being finished, replace the retort, and carefully close by lute its junction with the adopter, and leave the whole in this state till the contents of the retort have acquired a reddish-brown colour, which will take place in a day or two. Now proceed to distillation, by placing a pot of lighted charcoal beneath the retort, observing to heat it very gradually. The first impression of the fire drives off a little highly dephlegmated alcohol, but as soon as the mixture begins to boil, the ether itself passes over and condenses on the sides of the receiver in large streaks. It is now essentially requisite to keep the receiver as cool as possible, by the application of ice or of wet cloths wrung out in cold water and frequently renewed; and if this is properly attended to, by far the greater part of the ether will be condensed in the first receiver, whence it will flow into the vial beneath; a little, however, will pass through the second adopter into the second receiver, where it must be condensed by the same means as have already been recommended. The contents of the retort are to be kept moderately boiling, till sulphurous acid gas begins to pass through the quill of the second receiver, which may be known at once by its strong suffocating odour. As soon as this is perceived, the fire is to be withdrawn, and the vial is to be detached from the receiver, and its contents poured into a ground-stoppered bottle; being then replaced as before, the process of distillation is to be re-commenced till about six or seven ounces of a coloured liquid are produced, after which the operation is to be stopped. The original mixture of sulphuric acid and alcohol is thus divided into three separate products; namely, the residue in the retort, and the products of the second and first distillations. In the retort is a black thickish matter, smelling strongly of sulphurous and acetous acids, and intensely sour to the taste. If diluted with an equal bulk of warm water and filtered through pounded glass or clean white sand, it will be separated from the carbonaceous matter with which it was loaded, and by subsequent boiling the sulphurous and acetous acids will be driven off, leaving behind sulphuric acid in a considerable degree of concentration, and applicable to a variety of useful purposes. The product of the second distillation consists of two distinct liquids, the heaviest of which is acidulous

water, and the lighter an impure ether, called *oil of wine*, which may be separated from the water by inverting the vial that contains them in warm water; a little of the ether is in consequence converted into elastic vapour, which forces out of the vial the lower and heavier fluid. The product of the first distillation is impure ether, in quantity about  $17\frac{1}{2}$  ounces. Thus from 32 ounces of sulphuric acid and 40 ounces of alcohol there are procured about  $17\frac{1}{2}$  ounces of impure ether, and three ounces of oil of wine; and the sulphuric acid that may be recovered, taking into consideration its quantity and density, amounts to about 46 per cent. of that originally employed.

Ether, when fresh distilled, is contaminated by sulphurous and acetous acids and a little coloured oil, in consequence of which it is necessary to purify it by rectification. This is generally done by adding to the ether successive portions of caustic potash or soda dissolved in water, and shaking together the two fluids in a well closed bottle, after each addition of alkali, till the sulphurous odour is totally destroyed; the contents of the bottle are then to be poured into a retort, and by the application of a gentle heat, never amounting to ebullition, the ether will pass into the receiver in a state of great purity, leaving behind a watery saline liquor covered by a thin film of brownish-yellow oil. Scheele recommends that the alkali employed in rectification should be dissolved in alcohol instead of water; the advantage of which is that no spontaneous separation of the liquors takes place, and therefore the sulphurous and acetous acids are neutralized and separated with greater certainty. Distillation at a gentle heat will readily separate the ether from the other ingredients. A still cheaper and very effectual method of rectifying ether is the following, first employed by Mr. Woulfe. "Fill three-fourths of a bottle with the impure ether, add a little water and a portion of slacked lime; agitate the bottle with violence, and keep it for some time in cold water, before taking out the cork; if the smell of the sulphurous acid be not removed, add a little more lime and agitate a second time. Decant off the ether into a receiver, and distil it off." Another very cheap and ingenious process was invented by Pelletier. It consists in adding to the impure ether a little finely pulverized black oxyd of manganese. The mixture being corked up in a bottle, is to be well shaken four or five times a day for the space of a week, at the end of which time the sulphurous acid will have been converted into sulphuric, and will have combined with the manganese, from which the ether may be poured off without the necessity of distillation.

By any of the above methods ether is rectified sufficiently for any purposes to which it is usually applied; but if the greatest possible degree of purity is required, there should be added to the rectified ether successive portions of dry pulverized muriat of lime, till it ceases to be dissolved; from this mixture, by distillation with a very gentle heat, and keeping at the same time the receiver quite cold by the application of ice, an ether may be procured, probably entirely free from alcohol and water, and of the specific gravity of 0.65.

Rectified ether exhibits the following properties. It is a transparent colourless liquor, of a peculiar and to most persons an agreeably fragrant odour, and a hot penetrating, and somewhat suffocating taste. Its usual specific gravity, according to Lavoisier, is = 0.758. It is volatilizable at a lower temperature, and more rapidly than any other liquid, a considerable proportion being lost, especially in hot weather, by merely pouring it from one vial into another; hence the vessels in which it is kept ought to be very exactly closed, and for further security are often kept inverted in cold

water.

## ETHER.

water. It boils at  $98^{\circ}$  Fahr. under the usual atmospherical pressure, and at  $20^{\circ}$  in vacuo.

Owing to the extraordinary rapidity with which ether evaporates, it possesses a very great power of refrigeration. This is made obvious to the feeling by pouring a little into the palm of the hand; it is almost instantly volatilized, and the hand becomes painfully cold. So also if some fine tow is wrapped about the bulb of a small thermometer, and the blast from a pair of double bellows is let upon it, after it has been well soaked in ether, the mercury in the thermometer will, in the space of a minute or less, be lowered to  $0^{\circ}$  Fahr. Ether, notwithstanding its ready volatility, is capable of being congealed at a low temperature. If a small matras filled with this fluid is cooled down to  $-25^{\circ}$  Fahr. by a mixture of snow and muriat of lime, the liquor becomes gradually filled with brilliant transparent crystalline laminæ, resembling benzoic acid or oxymuriat of potash; and presently, especially at a somewhat lower temperature, the whole is congealed into a white almost inodorous mass. Ether is remarkably inflammable, taking fire instantly on the near approach of an ignited body; it burns with a large white flame and a little smoke, and is resolved into water, carbonic acid, and a minute quantity of charcoal. When passed through a red-hot earthenware tube, it is entirely decomposed, and a large production of carburetted hydrogen takes place. Ether remarkably increases the bulk of any of the permanent gasses to which it was added, as was first observed by Dr. Priestley. A small quantity of this fluid being mixed with oxygen confined over mercury, exactly doubled its bulk, nor could any additional quantity occasion a further dilatation. Nearly the same effect took place with atmospheric air, azot, hydrogen, nitrous gas, and carbonic acid; but by a slight agitation in water the ether was absorbed, and the gas resumed its former dimensions without any alteration of its original properties. If oxygen gas thus diluted by ether is set fire to, it burns rapidly, but does not explode; but if one part of this mixture is added to three parts of oxygen, the application of an ignited body, or of the electric spark, causes a violent explosion, the products of which are water and  $2\frac{1}{2}$  parts of carbonic acid. Hence it appears that one part of ether requires 6.8 of oxygen for its saturation, and that the proportion of carbon to hydrogen in sulphuric ether is nearly as 5 to 1.

Water and ether appear to combine with each other in two different proportions. If equal parts of these fluids are shaken together in a graduated tube, the ether will be found to have diminished in bulk about  $\frac{2}{3}$ , and the water to have enlarged in nearly the same proportion; the lower fluid consists of water saturated with ether, and the upper fluid is ether combined with a little water. The ether in this state is said to be *washed*, and acquires in consequence some properties which pure ether does not possess; in particular, it is now capable of dissolving caoutchouc with great ease, whereas this substance is acted on by pure ether only in a very imperfect manner. Phosphorus is soluble in ether, but the solution is not luminous. When ether is boiled with phosphorus, it often deposits crystals by cooling; agitation with water produces no change in this liquid, but the addition of a little alcohol causes an immediate turbidness, whence the sophistication of ether by alcohol may be detected by the addition of a few drops of phosphorized ether. The fixed alkalies seem incapable of uniting with ether, but ammoniacal gas is absorbed by it very copiously. The same may be observed of nitrous gas; but neither of these combinations hitherto been submitted to an accurate examination. Sulphuric acid acts on ether with considerable energy, especially if assisted by a gentle heat; it is converted

into a brownish oily fluid, much heavier than ether, called oil of wine, and at a higher temperature is changed into olefiant gas. With regard to the action of oxymuriatic acid on ether, a curious experiment is related by Mr. Cruickshank. "If we fill a bottle of the capacity of three or four pints with the pure oxymuriatic acid gas, taking care to expel the water as completely as possible, and then throw into it about a drachm or half a drachm of good ether, covering its mouth immediately with a piece of light wood or paper, in a few seconds white vapour will be perceived, moving circularly in the bottle; this will soon be followed by an explosion, accompanied by flame, at the same time a very considerable quantity of carbon will be deposited, and the bottle will be found to contain carbonic acid gas." Nitric acid excites a considerable effervescence in ether, and seems to convert it into oil of wine. The essential oils are soluble in ether, and it combines with alcohol in almost all proportions.

Concerning the theory of etherification, much has been written, and many experiments have been made by able chemists, without, however, obtaining the satisfaction that could be wished. According to Macquer, ether is a substance intermediate between alcohol and oil, and alcohol approaches to the state of oil precisely in proportion as it parts with its water of composition. But though it is true that the production of water accompanies the conversion of alcohol into ether, and of ether into oil of wine, yet this is by no means the only phenomenon, so that the theory of Macquer is, at best, imperfect, since the deposition of charcoal, and the generation of acetous acid, are not at all accounted for. According to Pelletier, Chaptal, and others, the whole process of etherification consists in a transfer of oxygen from the sulphuric acid to the alcohol: the disengagement of sulphurous acid accompanies the production of ether, and therefore shews that the sulphuric acid is deoxygenated: the oxygen, thus separated, does not come over in the state of gas, and therefore must be combined with the alcohol forming ether. But in reply, it may be observed, that this mode of explanation accounts for only a few of the phenomena, and that the preparation of ether, if carefully managed, may be carried on without the disengagement of any sulphurous acid. The most elaborate enquiry into this intricate subject was undertaken by Vauquelin and Fourcroy, which we shall now proceed to detail, though it is by no means so complete and satisfactory as to preclude the necessity of further researches. The facts and observations by which this theory is supported are the following.

If one part of alcohol and two of sulphuric acid are mixed together, the temperature rises to about  $200^{\circ}$  Fahr.; the mass immediately acquires a deep brownish-red colour, which deepens into black in a few days after, and at the same time exhales a vapour manifestly ethereous.

Equal parts of concentrated sulphuric acid and rectified alcohol acquire on mixture a temperature of  $190^{\circ}$  Fahr.; bubbles of gas are extricated, the liquor becomes turbid and opalescent, and at the end of a few days acquires a deep red colour. The whole being then transferred to a distillatory pneumatic apparatus, and being heated to  $107^{\circ}$  Fahr., ebullition takes place, and ether passes over into the recipient; if the operation is carefully conducted no elastic fluid is disengaged, and the vapour, when condensed, is found to be only water and ether. When the liquor thus obtained amounts to about half of the alcohol employed, sulphurous acid begins to be manifest, and, in a short time, the production of ether ceases, and is succeeded by oil of wine, accompanied by acetous acid. The contents of the retort being kept boiling, and becoming more and more concentrated as

the

the distillation proceeds, are constantly acquiring a higher temperature; when this amounts to about  $234^{\circ}$  Fahr., olefiant gas begins to come over, and continues till the oil of wine ceases to flow. At this period carbonic acid gas first makes its appearance, and water and sulphurous acid still continue to be produced, the residue in the retort being in the mean time reduced to little else than sulphuric acid thickened by charcoal.

From these facts the able chemists who observed them have concluded,

1. That the spontaneous action of alcohol and sulphuric acid, when this latter is considerably in excess, is sufficient for the formation of ether without the assistance of any extraneous heat, and that by duly proportioning the two substances, the alcohol might be wholly decomposed and made to yield all the ether of which it is capable when treated in the usual manner.

2. That the formation of ether is not owing to the affinity of the oxygen of the sulphuric acid, for the hydrogen and carbon of the alcohol, because in the preparation of ether no sulphurous acid gas is evolved till the production of ether has almost ceased. It must therefore be the entire attraction of the acid for one or more of the elements of the alcohol that determines its decomposition: now since water is formed during the whole process, and, since the attraction of sulphuric acid for this substance is very powerful, it appears likely that this is the cause that destroys the equilibrium of the affinities by which the elementary particles of alcohol are retained in combination, and induces the oxygen and hydrogen to unite and form water. Hence it might at first sight be supposed that ether differs from alcohol in containing a smaller proportion of oxygen and hydrogen. This however will not be found to be the case, when we advert to the deposition of charcoal, which, equally with the production of water, accompanies the formation of ether: now the amount of charcoal deposited is greater in proportion to that which is left, than the hydrogen of the water compared to what remains in the ether; therefore this latter fluid, though composed of the same elements as alcohol, differs from it in containing a smaller proportion of carbon compared with the hydrogen. During the progress of distillation the heat to which the materials in the retort are exposed is constantly increasing, and (the affinity of the acid and alcohol also augmenting) the acid itself is at length decomposed, sulphurous acid is generated, and the excess of oxygen deprives the alcohol of part of its hydrogen whence results the oil of wine, differing from ether in containing a larger proportion of carbon; and in confirmation of this, it may be observed, that the charcoal deposited during the production of oil of wine is not so abundant as during the generation of ether.

Hence as (according to the authors of the above hypothesis) no decomposition of the sulphuric acid takes place during the formation of ether, the agency of the acid is partly that of detaining the alcohol in a temperature more than sufficient for the volatilization of this fluid when uncombined, and partly that of assisting the caloric to decompose the alcohol in consequence of its own powerful affinity for water.

A circumstance, however, first remarked by Scheele, but which has hitherto failed to obtain the notice to which it is so well entitled, sufficiently proves that in the formation of ether the acid employed acts a much more important part than is assigned to it in the theory of Vauquelin and Fourcroy. The admirable chemist above-mentioned states that if sulphuric ether be duly rectified by agitation with caustic alkali and subsequent distillation, it occasions no precipitate with barytic salts; but if to the ether thus purified there be

added nitric acid, a copious precipitate is then produced by any of the soluble salts of barytes, indicating the presence of sulphuric acid. This fact strikingly points out that a portion of the base of the acid in a more or less deoxygenated state actually combines with the alcohol to compose ether. A like fact respecting muriatic ether is also mentioned by Scheele, namely, that though this ether, when rectified, occasions no decomposition of nitrated silver, yet the watery residue, after combustion of the ether, occasions a copious precipitate of muriated silver when mixed with the nitrat of this metal.

§ 2. *Nitrous ether.*—Although nitrous ether appears to have been known to Basil Valentine and Kunkel, yet the mode of its preparation being kept a secret, it soon ceased to be attended to by chemists, till in the year 1740 it was re-discovered by Duhamel, and afterwards was more particularly described by Navier, Sebastiani and others. It was prepared by Navier in the following manner. Put 12 ounces of rectified alcohol into a strong bottle, and add to it gradually and at intervals 8 ounces of strong nitric acid; after each portion of acid the liquors are to be well mixed by agitation, and the bottle is to be kept close corked and immersed up to its neck in ice and water; when the whole of the acid has been added, the bottle is to be well corked and further secured by a leathern cap. A stratum of ether rises by degrees to the surface of the liquor, and after five or six days the cork is to be pierced by a needle in order to let out the nitrous gas formed during the process: this gas having escaped, the cork is to be drawn, and the whole contents of the bottle being poured into a separatory funnel, the ether is thus procured unmixed with the heavier fluid on which it floats. This is, however, a very rude way of proceeding, and is attended with the utmost risk to the apparatus, the ether obtained also is in small quantity, and very impure. In order to prevent the violent and rapid action of the concentrated acid on the alcohol, which is the chief difficulty in the preparation of nitrous ether, Dr. Black proposed to interpose a thin stratum of pure water, and Fischer on the same principle made use of a little weak spirit of nitre for the same purpose. M. Dölsfus, from a careful repetition of the latter process, obtained the following result. Upon two ounces of very strong nitric acid he poured gently six drachms of the same very much diluted, and upon this three ounces of rectified alcohol. The bottle was loosely corked and suffered to stand undisturbed for three days; at this time the lower liquor appeared perfectly homogeneous with a stratum of ether floating above it. The whole being put into a retort and subjected to a gentle heat, there were obtained two ounces and a drachm of very pure ether unmixed with any acid, and the residue in the retort consisted of weak acetous acid mixed with oxalic acid, nearly the whole of the nitrous acid having been decomposed.

The last mode by which nitrous ether may be prepared, that we shall mention, and which on the whole appears to be the best, consists in mixing together alcohol and sulphuric acid, and pouring the liquor upon pulverized nitre; the sulphuric acid disengages the nitre, which immediately re-acts on the alcohol, and ether is the result. The able chemist whom we have already mentioned has shewn the excellence of this method by the following experiment. Having put into a retort four ounces of perfectly dry and pulverized nitre, he added to it a mixture consisting of two ounces of concentrated sulphuric acid, and four ounces of alcohol. The whole being submitted to distillation, there came over first six drachms of dulcified spirit of nitre, and then three ounces of a liquor from which by subsequent rectification were procured two ounces of pure ether.

Nitrous ether, when recently made, contains in loose combination a considerable quantity of nitrous gas, which in some degree modifies its properties, and renders it peculiarly liable to burst the bottles in which it is kept, especially in warm weather. This loss and trouble, however, may be avoided by rectifying the ether, which is best done in the following way. Pour into a strong vial so as to fill it two thirds, one part of ether and four parts of pump-water, and agitate it cautiously at first, frequently removing the thumb from the mouth of the vial in order to afford a free passage to the disengaged nitrous gas: when no more of this gas is given out add a quantity of dry pearlsh equal in weight to the ether, and shake the whole well together; then put the mixture into a tubulated retort and proceed to distillation, taking care that the temperature does not exceed 120° Fahr.; the ether will pass into the receiver quite pure, and may be kept for any length of time in strong well closed bottles, with no more risk of accidents than sulphuric ether is subject to.

Nitrous ether resembles sulphuric ether in most of its properties; it has, however, a dilute yellow colour, and a somewhat different odour and flavour; this appears to be owing to the presence of a little resinous matter, from which it can never be entirely freed; by repeated distillations from fresh parcels of dry white sugar, as Deyeux has observed, this impurity may, in great part, be separated, and in proportion as this takes place the ether becomes more and more analogous to that prepared by sulphuric acid.

Nitrous ether appears capable of uniting with nitrous gas in two proportions; when the ether is in excess it forms nitrous ether in the state in which it appears previous to rectification; when the nitrous gas exceeds the ether it forms a permanently elastic fluid that has obtained the name of *etherized nitrous gas*. The preparation of this differs only in the rapidity with which the nitrous acid and alcohol are made to act on each other: when the combination takes place very slowly much ether and little etherized gas are the result, but when the contrary is the case, these two products are formed in an inverse proportion. If equal parts of alcohol and strong nitrous acid are mixed together at the common atmospheric temperature, or at a higher heat in proportion as the acid is diluted, a very rapid and copious effervescence takes place, a little ether is condensed in the receiver, and a large quantity of gas passes through the conducting tube, the first portions of which are etherized nitrous gas, and the latter common nitrous gas. What remains in the retort is acetic acid with a little oxalic acid. The properties of etherized nitrous gas (according to Van Diemen and his associates, to whom we are indebted for its discovery) are the following. It has a disagreeable ethereal odour, exactly resembling that of olefiant gas when treated with oxymuriatic acid. By the application of flame it takes fire and burns with a yellowish lambent flame like alcohol; after the combustion has ceased, the vessel in which it was carried on contains a vapour of singular pungency. Water absorbs this gas, but requires a considerable time to effect this, except agitation is had recourse to, resembling, in this respect, carbonic acid. Alcohol produces the same effect as water, and takes up the gas not only more rapidly, but also in larger proportion. A solution of caustic potash also dissolves it, but with considerable difficulty, and on the addition of sulphuric or muriatic acids the etherized gas is again set at liberty unaltered in any of its properties. Ammonia, whether liquid or in the gaseous state, is incapable of contracting any union with it; the same is the case with oxygen gas at the common temperature, but a mixture of the two airs, when inflamed, produces a most violent explosion; sulphuric acid immediately decomposes this gas, by absorbing the

ether, the nitrous gas retaining its elastic state. Sulphurous acid produces the same effect, only it requires some days for this purpose. If sulphuric acid, previously diluted with an equal weight of water, is placed in contact with this gas over mercury, its action is greatly retarded, the diminution of volume in the inclosed air takes place much more slowly, and even after some days a portion of ether is retained by the nitrous gas, which in consequence acquires the property of enlarging the flame of a taper that is immersed in it, in the same manner as nitrous oxyd does. Nitrous acid, according to the degree of its concentration, absorbs either wholly or in part, the ethereous portions of the gas, and the same may be observed of muriatic acid.

Etherized nitrous gas, when passed through a red-hot tube, deposits a little oil, and by subsequent washing in lime-water is freed from some carbonic acid; the residue is nitrous gas, mixed or combined with common carburetted hydrogen, and is not acted on by the sulphuric, nitric, or muriatic acids, by caustic potash or alcohol. The addition of oxygen gas produces red vapours, the nitrous gas is converted into acid, and the gaseous residue is carburetted hydrogen.

§ 3 *Muriatic ether*.—After chemists had shewn the production of ether by means of the sulphuric and nitric acids, it was natural to attempt its preparation by the muriatic acid. But this latter, in its usual state of dilution with water, has no action on alcohol, and therefore the various modes that were first practised to obtain muriatic ether entirely failed. A few chemists were said to have succeeded by employing simple muriatic acid, but in a more concentrated and dry state than the common liquid acid; the process, however, was both difficult and doubtful, and muriatic ether can hardly be said to have been known till Rouelle discovered that it might be prepared by distilling together alcohol and the smoking liquor of Libavius, which is a concentrated muriat of tin in its highest state of oxydation. The marquis de Courtanvaux, having repeated the process of Rouelle with great care, proposes the following as the best method of making the substance in question. Mix together in a retort three parts of the fuming muriat of tin and one of alcohol; a considerable degree of heat is immediately excited, and a white suffocating vapour arises, which, however, soon disappears on agitating the mixture. As soon as an ethereous odour is perceived, let two balloon receivers be luted on, and kept as cool as possible; then by the application of a gentle heat to the retort there comes over first a little dephlegmated alcohol, which is succeeded by the ether: by an increase of temperature a few drops of coloured oil are produced, and there arises, partly in the form of a soft butter and partly in that of a dense brown liquid, a quantity of smoking muriat of tin, part of the metallic oxyd remaining in the retort as a grey powder. When the ether thus procured is mixed with pearlsh, a copious effervescence and precipitation take place, owing to the decomposition of some muriat of tin contained in the ether; after which, by distillation at a gentle heat, the ether arises in a state of great purity, amounting to half the impure product of the first distillation.

Several other of the metallic muriats have been found to be equally efficacious with the liquor of Libavius; the corrosive muriats of antimony and of arsenic, the muriats of bismuth and zinc, and the red muriat of iron, have in particular been used with success in the preparation of muriatic ether. Scheele.

Scheele, the discoverer of oxymuriatic acid, was induced to try the effect of this in the preparation of muriatic ether. For this purpose he put three ounces of alcohol into a receiver,

receiver, with which was connected a retort holding two ounces of common salt, upon which was poured an equal weight of sulphuric acid; the muriatic acid thus disengaged passed into the receiver, where it combined with the alcohol; and this, when saturated with acid, was transferred to another retort, containing three ounces of black oxyd of manganese in fine powder; the mixture instantly assumed a green colour, and presently after became so hot as to boil. When the ebullition had ceased, there was found in the receiver a liquor, from which, on mixture with water, a quantity of ether immediately separated. The same method is recommended by Van Mons, except that he employs only one fourth of the manganese used by Scheele, and performs the second distillation in a Woulfe's apparatus, the bottles of which contain a solution of caustic potash, by which the acid is prevented from re-acting on the ether.

Another mode of applying oxymuriatic acid to the preparation of ether, first practised by Scheele, is mentioned by Pelletier, and deserves to be repeated, as being perhaps the most expeditious and economical of any. He introduced into a large tubulated retort a mixture of eight ounces of manganese, and 16 ounces of decrepitated common salt, upon which he poured a mixture of 12 ounces of sulphuric acid, and eight ounces of alcohol. From this mass ten ounces were drawn off by distillation at a gentle heat, which, by subsequent rectification, yielded four ounces of ether.

It deserves to be remarked, that the ether prepared by oxymuriatic acid generally deposits, during its rectification with potash, a considerable quantity of a clear aromatic and bitter oil, which sinks in drops to the bottom of the vessel; the ether also, according to Dollfus, at least before rectification, is completely miscible with water when shaken with it for some time. The preparation of ether, by means of simple muriatic acid, is not easy, and was readily supposed to be impossible by some of the leaders of the modern school of French chemists, because it contradicted one of their early theories on the process of etherification; yet Beaumé, a chemist of great experience and unquestioned veracity, had affirmed, that he had obtained a small quantity of ether, by mixing together alcohol and muriatic acid, both of them in the state of vapour. The practicability of this method appears also to be established beyond doubt by the following formula of M. Basse. Keep a quantity of common salt in fusion for about an hour, in order to drive off all the water of crystallization, then pulverize it, and put 40 parts into a tubulated retort, connected with a Woulfe's apparatus, in the first bottle of which are to be poured 20 parts of most highly rectified alcohol; then add to the salt in the retort 20 parts of the strongest sulphuric acid, and proceed to distillation by a gentle heat, keeping the bottle holding the alcohol as cool as possible. When the alcohol is saturated with acid, transfer it to a retort, and distil over about one half of it; agitate this portion with an alkaline ley, and the ether will presently separate and float on the surface, whence it may be obtained by decantation or distillation. The quantity of ether from the above materials amounts to about five parts.

Muriatic ether has a striking resemblance to that prepared by sulphuric acid; its specific gravity, however, is greater, amounting, according to Hermbstadt, to 0.84; its taste also has a peculiar astringency like alum, and when burning it exhales a strong acid odour, somewhat resembling that of sulphurous acid.

§ 4. *Fluoric ether.*—All that we know of this substance is derived from the discoveries of Scheele. He first impregnated rectified alcohol with fluoric acid gas, by distilling

pulverized fluor spar with sulphuric acid, and placing alcohol in the receiver; the smoking spirit thus obtained was distilled with a gentle heat, but no sign of ether made its appearance. Another portion of the acidulated spirit was then mixed with black oxyd of manganese, and by subsequent distillation an ethereous fluid came over, from which, by subsequent rectification, a little ether was obtained of a very agreeable odour, resembling nitrous ether.

§ 5. *Acetic ether.*—Acetic ether was first discovered by the Count de Lauraguais; the method of its preparation was by distilling together equal parts of alcohol and acetic acid. Scheele, Pörner, Bergman, and other chemists, repeated this process ineffectually, and hence were induced to suspect some error. In consequence of these doubts, Pelletier entered into a careful examination of the subject, and has both shewn the reason of the failure of Scheele, and has given the proper method by which to succeed. He distilled together equal parts of alcohol and acetic acid, and drew off a little more than half; this liquor was acidulous, and had an ethereal odour, but no true ether could be made to separate. He then mixed together 12 ounces of strong radical vinegar, and the same quantity of alcohol, and distilled over one half of it at a boiling temperature; this product he poured back into the retort and recommenced the distillation; the produce of this and of a third distillation were in like manner recobated, and having distilled the whole again for the fourth time, he finally obtained 12 ounces of an ethereous fluid; with this he mixed a quantity of carbonated potash, sufficient to saturate the acid which it contained, and then submitted it to gentle distillation. The first six ounces that came over were pure acetous ether, the next four ounces also contained ether, but not so pure as the former. It is remarkable that during the cobinations a considerable absorption of air took place.

Scheele obtained acetous ether in a much more compendious manner, by mixing together acetat of potash, or of lead, or of copper, with alcohol, and then adding as much sulphuric acid as was requisite to decompose the acetous salt, and distilling the mixture at a low heat. The produce being shaken with water, the ether rises to the surface and may be poured off. From 16 parts acetat of lead, six parts strong sulphuric acid, and nine parts of water, Bucholz obtained six parts rectified ether.

Acetic ether always retains the odour of the acid by which it is formed; it is not so volatile as the ethers procured by the mineral acids; it burns with a lambent blue flame, like alcohol; it is soluble in a little more than twice its bulk of water, and is decomposable into acetous acid by repeated distillations at a very gentle heat.

Various other acids have been distilled with alcohol for the purpose of procuring ether, but with little or no success. Oxalic acid, with an equal weight of alcohol, yielded Bergman a watery somewhat etherized alcohol. Benzoic acid and alcohol, according to Scheele, afford no ether, but when a little common muriatic acid is added to the mixture, an ethereous liquor comes over, of which part floats on water and part sinks in the same fluid. The ether, or the lighter portion, has the odour of benzoic acid, burns with a clear flame and smoke, and is about equal in volatility to acetic ether. The phosphoric, boracic, tartarous, citric and fuccinic acids, were found by the same able chemist to be incapable of producing ether, either by their own action on alcohol, or when mixed with oxyd of manganese or muriatic acid.

ETHER, in *Ancient Geography*, a town of Palestine, in the tribe of Juda, which afterwards was assigned to the tribe of Simeon.

**ETHEREAL OIL.** See *OIL, volatile or essential.*

**ETHEREGE, GEORGE,** in *Biography*, chiefly known as a writer of comedy, was born in the vicinity of London about the year 1636. Little is known of his early years, but it is supposed he was educated at Cambridge; spent some time in foreign travel, and afterwards entered himself at one of the inns of court. His talents were but ill adapted to the laborious profession of the law; he was fond of gay and polite company, and became a writer for the stage. In 1664, his first comedy, entitled "The Comical Revenge, or Love in a Tub," was presented to the town, and well received. The author was immediately enrolled among the wits of the age. His next piece is thought to have been entitled to more praise for wit than for morality. It is entitled "She would if she could;" its licentious tendency was justly reprobated by the "Spectator," who says he knew of but one author who had professedly written a play upon the desire of multiplying our species, and that is the polite sir George Etherege in the play of "She would if she could:" "Other poets," he adds, "have here and there given an intimation, that there is this design under all the disguises and affectations which a lady may put on, but no author except this has made sure work of it, and put the imaginations of his audience upon this one purpose, from the beginning to the end of the comedy." His next piece was not produced till the year 1676; it was entitled "The man of the mode, or sir Fopling Flutter," and dedicated to the second duchess of York, Mary of Modena. It was very popular, and regarded as a true model of polite comedy; one of its principal characters was said to be a representative of the earl of Rochester, the finished fine gentleman and man of pleasure. Etherege lived a dissipated life, and in a few years injured his fortune and constitution. With a view of maintaining his rank in society, he paid his addresses to a lady of considerable fortune, who refused to marry him, unless he could procure the honour of knighthood. This he readily obtained, and upon the accession of James II. he was sent out envoy to Ratibon, where he resided some time, and from whence he wrote letters which are favourable specimens of his talent for easy pleasantry. He died soon after the revolution, but the account of the time and manner of his death has been differently related. By some he is supposed to have died in his native country soon after his return from France, whither he had been on public business, and by others it is said, that it happened at Ratibon by a fall down stairs. Besides the comedies already mentioned, Etherege was author of many smaller poems. His letters to the duke of Buckingham are in the *Biographia Britannica*, to which the reader is referred.

**ETHERINGTON'S BAY,** in *Geography*, a bay on the north-west coast of the island of St. Vincent; a little to the north of Chateau Belair bay.

**ETHESIUS LAPIS,** a name given by some authors to the chrysolite.

**ETHICAL GOOD, ETHICAL possible.** See the respective articles.

**ETHICS, Ethik,** the doctrine of manners, or the science of moral philosophy. See *PHILOSOPHY* and *MORALITY*.

The word is formed of *ethos, mores, manners*, because the scope or object thereof is to form the manners.

Gale makes ethics only the first part or branch of moral philosophy, *viz.* that which regards private persons, or in a private capacity.

By manners or morals is here meant a way, or manner, of living confirmed by custom or habit, or certain habitudes of doing, or actions which are often repeated, which, if

they be according to right reason, the morals or manners are said to be good, otherwise, evil and vicious.

Hence the object of ethics is the exercise of right-reason in all our affairs, actions, and relations; or it is a man himself considered as dirigible, and to be conducted according to reason: and the end of ethics is to make him good and happy: so that if a man conducted himself according to right reason in all the circumstances of his actions, affairs, and relations, he would arrive at the highest pitch of moral perfection and beatitude.

Whence ethics may be defined a right manner of thinking in order to attain to human felicity, or a science where-by man is directed to conduct his will, and the actions thereof, so as to live well and happily. See *WILL*.

The principal, nay, the only topics thereof, are happiness and manners, whence arise two parts or branches of ethics; the first on moral happiness, considered as the end; and the second on moral virtues or good manners, as the means to arrive at that end.

**ETHICOPROSCOPTÆ,** formed of *ethos, manners*, and *proscopos, offendo, I offend*, in *Antiquity*, the name of a sect. Damascenus, in his *Treatise of Heresies*, tells us, that the denomination of Ethicoproscoptæ was given to such as erred in matters of morality and things relating to practice that were to be done or to be avoided, &c. who blamed things laudable and good in themselves, or recommended or practised things evil. On this footing the Ethicoproscoptæ, though a numerous body, were no particular sect.

**ETHIOPIA,** in *Ancient Geography*, was a name given to several countries, both of Asia and Africa, whose inhabitants were either perfectly black or of a swarthy complexion; but *Ethiopia*, in a more restricted application of the term, or *Ethiopia propria*, was limited on the north by Egypt, extending to the lesser cataract and the island Elephantina; on the west by Libya interior; on the east by the Red sea; and on the south by a part of Africa unknown to the ancients, but probably comprehending that space which includes the modern kingdoms of Girgiro, Alaba, Machida, and part of Adel or Zeila. Proper Ethiopia, however, seems to have varied in extent at different periods; but for several ages it seems to have been the tract which at this day comprehends the kingdoms of Dongola, Sennaar, and Abassia, with part of Adel or Zeila; and consequently to have taken up 17 degrees of longitude, and to have reached from the tropic of Cancer to within six degrees of the line. Some geographers have restricted it to the tract of country that lies between Egypt and Abyssinia, about 600 miles in length, and 500 in breadth, which was called by the Arabian geographers Nubia.

The proper Ethiopia was anciently distinguished by a variety of appellations. Sometimes it was called India; sometimes Cephonia; and most usually Abasene, in sound and signification approaching very near to the modern Habash, Habesh, or Abassia. We also find Chaldæa, Assyria, and even Persia denominated Ethiopia by some authors of reputation; and it must be allowed, that the ancients called all those countries, extending themselves beyond each side of the Red sea, indiscriminately India or Ethiopia.

According to the Jews, the LXX, the Vulgate, and other versions, Cush, when applied in scripture to a country, is always to be understood of the proper Ethiopia. This opinion is supported by Philo, Josephus, Eupolemus in Eusebius, Eustathius, the author of the Alexandrian Chronicle, and the concurrent testimony of the Greek and Latin fathers. See *CUSH*.

Ethiopia did not abound in cities and towns of any considerable

## ETHIOPIA.

siderable note. *Auxume*, *Auxumis*, or *Axome*, reckoned the metropolis of Ethiopia, was undoubtedly the same city as the modern *Axuma*, or *Axum*. This country was extremely mountainous, and therefore the climate in different parts of it was very various. (See *ABYSSINIA*.) The days and nights, as Ethiopia lay betwixt the tropic of Cancer and the line, were for the most part nearly equal. The winds that blew on the mountains were, generally speaking, salubrious and pleasant; but the atmosphere over the plains stagnated and became unwholesome. The soil in those parts that admitted of cultivation was extremely fertile, and produced vast quantities of grain, pulse, and fruit. It abounded with metals, particularly gold, minerals, vegetables, and a great variety of animals. (See *ABYSSINIA*.) The most famous river that waters this country is the Nile. (See *NILE*.) The chief ports and emporia of ancient Ethiopia were those of *Adulis*, *Mondus*, *Opere*, *Mosylon*, and the principal city of the *Aualitæ*, seated upon the Red sea. The Arabs imported from their country into these ports fruit, corn, wine, and cloaths; and exported from thence to *Ocelis* and *Mufa*, opposite harbours in Arabia, spices, cassia, perfumes, ivory, myrrh, and several other commodities. The most noted islands pertaining to Ethiopia were *Meroe*, the *Sporades* of *Agatharcides*, *Altratae*, *Ara Palladis*, *Gythitis*, *Myronis*, *Daphnine*, *Magi*, *Acanthine*, *Iſis*, *Mondus*, and *Menuthias*.

According to *Pliny*, Ethiopia was anciently divided into 45 kingdoms, of which the most powerful and flourishing was *Meroe*; but he does not inform us, whether they were independent of each other, or under one supreme head. There is reason to believe, however, that the kings of Ethiopia always ruled with an uncontrollable sway. If we admit the Ethiopian tradition, that a long succession of princes, descended from *Solomon*, reigned in this country, it can scarcely be denied, that their authority was unlimited, as that of the Hebrew monarch knew no bounds. It appears from *Strabo* and *Pliny*, that some Ethiopic nations were governed always by queens, whose common name was *Candace*, as that of the Egyptian kings was *Pharaoh*, and *Ptolemy*. From *Diodorus Siculus* we learn, that a great part of Ethiopia was composed of several elective monarchies, the heads of which were chosen out of their priests; and that all these princes made the laws of their respective kingdoms the basis of their government. According to *Diodorus Siculus* the laws of Ethiopia agreed in substance with those of Egypt; which the Ethiopians accounted for by the assertion, that Egypt was first peopled by colonies that migrated out of their country. *Herodotus*, however, represents the Ethiopians as having been civilized by the Egyptians, and as having learned the customs and manners of that people at so late a period as the reign of *Psammitichus I.* *Jupiter Ammon*, according to the Greek and Latin authors, appears to have been the principal object of religious worship in Ethiopia; though the natives paid likewise divine honours to *Iſis*, *Pan*, *Hercules*, *Æsculapius*, and others, whom they considered as the greatest benefactors to mankind; and if these authors may be credited, their religion differed not much from that of the Egyptians. *Diodorus Siculus* tells us, that the Ethiopians valued themselves upon their being the first nation that had a religious establishment; and for this reason they believed, that their sacrifices were more acceptable to the gods than those offered by any other people. He assures us, however, that some of them were atheists, who looked upon the sun, on account of his scorching rays, as their implacable enemy. If a tradition of the modern *Abassines* could be relied on, the Ethiopians, or at least a considerable part of them,

adhered zealously to the law of *Moses* from the time of *Solomon* till their conversion to Christianity. According to this tradition, the queen of *Sheba*, whom our Saviour calls the queen of the south, and who ruled over a powerful nation of Ethiopia, had a son by *Solomon* named *Menileek*, who was educated at that prince's court, and instructed, under the care of his father, in the law of God. Being afterwards anointed king of Ethiopia, and sent home to take possession of his kingdom, at the desire of several eminent Israelites and doctors of the law that attended him, he introduced his father's religion, which continued among his subjects and their posterity till the time of *St. Athanasius*. See *ABYSSINIA*.

Ethiopia, in ancient times, was a country of vast extent, inhabited by different nations; and, therefore, it is natural to suppose, that a considerable variety of languages, or at least of dialects, must have prevailed in it. The most ancient of these was that called the Ethiopic, into which the scripture was formerly translated, and in which all the books of the *Abassines*, both sacred and profane, are written. According to some authors, this language nearly resembles the *Chaldee*; but, according to *Ludolfus*, who spent 60 years in the study of it, it bears as great an affinity to the *Hebrew* and *Syriac*, and approaches nearer still to the *Arabic*, from which it appears to be immediately derived. *Ludolfus* asserts, that a competent knowledge of the *Hebrew*, or any other of the oriental tongues, will enable a student soon to make a very rapid progress in the Ethiopic. The purest dialect of this tongue was that used in the kingdom of *Tigré*, where *Axuma* and the old Ethiopian kings resided. Upon the failure of the *Zagæan* line, a *Sewan* prince ascended the throne, upon which the *Amharic* dialect was introduced at court, and gradually diffused over the whole empire. (See *ABYSSINIA*.) From comparing the ancient Ethiopic alphabet, as given by the learned *Job Ludolfus*, in his "History of Ethiopia," with the old oriental alphabets, it seems not improbable, that some of them were derived from the old *Affyrian*, *Phœnician*, *Samaritan*, and *Syriac* characters. The number of letters likewise in this alphabet, and the names of several of them, tend to establish the same supposition; though *Ludolfus* believes these characters to have been invented by the *Axumites* or *Ethiopians* themselves, and to be much older than even the *Cufic* character of the *Arabs*. The Ethiopians both write and read from the left hand to the right, contrary to the custom of the orientals: a circumstance which indicates that their alphabet was not entirely of the same extraction with that of the *Arabs*.

The Ethiopians agreed in several points with the *Egyptians*, though they had many customs peculiar to themselves, some of which were very singular and uncommon. From this mutual agreement in most of their laws, their splendid funerals, the dedication of their princes, the several colleges of priests, circumcision, and most of their sacred and civil institutions, it is highly probable that the same arts, sciences, and learning, as well as religion, prevailed in both nations.

The Ethiopians were naturally bold and intrepid, but violent in their temper. They likewise surpassed the people of most other nations in beauty and size, to which a proportionable degree of strength was generally annexed. According to various authors, the proper ancient Ethiopians were, in general, perfectly black, as we find their posterity at this day, though those of some particular cantons were white, called by *Pliny* white Ethiopians. Their women were strong and lusty, and brought forth their children with little pain. From the testimony of *Herodotus*, compared with the relations of some modern authors, it is not

unlikely, that they died of old age, a few only excepted, who fell by the sword, or were devoured by wild beasts, as Sallust has observed of the ancient Africans. *Anc. Un. Hist.* vol. xvi. See **ABYSSINIA** and **CUSH**.

**ETHIOPIA**, in *Modern Geography*, is a denomination including the countries of Nubia, Abyssinia, Abesh or Abex, and Anian, which are bounded by Egypt and the desert of Barca on the north; by the Red sea and the eastern ocean on the east; by Zanguebar and Caffraria on the south; and by Guinea, Nigritia, and Zaara, on the west. Nevertheless, all the countries still, according to the ancient division, that lie almost in a straight line from Egypt to the Cape of Good Hope, may be comprehended under the general name of Ethiopia. Ethiopia is divided into Upper and Lower, the former including Nubia and Abyssinia; and the latter comprehending all the kingdoms south of the equinoctial line, as Congo, Lower Guinea, Caffraria, Monomotapa, &c. which see respectively.

**ETHIOPIC VERSION.** See **BIBLE**, *Ethiopic*.

**ETHIOPIC Year.** See **YEAR**.

**ETHLEC**, in *Ancient Geography*, a town of Upper Mæsia, according to Antonine's Itinerary.

**ETHMOID**, or **ETHMOIDAL**, in *Anatomy*, a name given to one of the bones of the head. See **CRANIUM**.

**ETHNARCHA**, **ETHNARCH**, formed of *ethos*, nation, and *αρχη*, command, a governor and ruler of a nation.

There are some medals of Herod I. surnamed the *Great*, on one side whereof is found *Ἡρῶδου*, and on the other *Ἐθναρχου*, q. d. *Herod the Ethnarch*. After the battle of Philippi, we read that Antony, passing over into Syria, constituted Herod and Phafael his brother tetrarchs, and in that quality committed to them the administration of the affairs of Judea. (*Jos. Ant. lib. xiv. cap. 23.*) Herod therefore had the government of the province before ever the Parthians entered Syria, or before Antigonus's invasion, which did not happen till six or seven years after Herod was commander in Galilee. (*Jos. lib. xiv. cap. 24, 25.*) Consequently Herod was then truly ethnarch, he can be no otherwise denominated; so that it must have been in that space of time that the medals were struck, which only gave him this title: which medals are a confirmation of what we read in history of the government which that prince was intrusted with before he was raised to the royalty.

Josephus gives Herod the appellation of tetrarch in lieu of that of ethnarch; but the two terms come so near to each other, that it is easy to confound them together.

Though Herod the Great left by will to Archelaus all Judea, Samaria, and Idumea, yet Josephus tells us he was then only called ethnarch.

**ETHNOPHRONES**, in *Antiquity*, a sect of heretics in the seventh century, who made a profession of Christianity, but joined thereto all the ceremonies and follies of paganism, as judicial astrology, fortileges, auguries, and other divinations.

They derive their denomination from *ethos*, nation, and *φρον*, thought, sentiment. q. d. *paganizers*, or persons whose thoughts or sentiments were still heathen or gentile.

They practised all the expiations of the gentiles, celebrated all their feasts, and observed all their days, months, times, and seasons. See *Damascenus*, *Hæres. N<sup>o</sup> 94.*

**ETHOLOGUS**, among the *Ancients*, a mimic, or actor, who could represent all the various habits and dispositions of the mind.

**ETHOPEIA**, or **ETHOPEA**, in *Rhetoric*, called also *Ethology*, a draught or description, expressing the manners, passions, genius, tempers, aims, &c. of another person.

The word is of Greek original, being formed of *ethos*, *mos*, *consuetudo*, and *ποιω*, *facio*, *fungo*, *describo*. Quintilian, lib. ix. cap. 2. calls this figure *imitatio morum alienorum*; and in Greek, *μυμησις*, *imitation*. In English we denominate it a *picture* or *character*.

Such is that beautiful passage in Sallust, in his "Bellum Catilinarium," wherein he gives us a picture of Cataline: "He had an uncommon strength both of body and mind, but an ill-turned and wicked disposition. When very young, his great pleasure was in intestine broils, rapine, slaughter, and civil discord. His body was formed to undergo fasting, cold, and watching, beyond all belief. His mind was daring, deceitful, and various, and could imitate or accommodate itself to every body; he was extremely covetous of other people's goods, and profuse of his own. His lusts and desires were very high; his stock of eloquence considerable, but he had little or no discretion."

The ethopœia is divided into *profopographia* and *ethopœic*, properly so called; the former of which is a picture of the body, countenance, make, dress, gait, &c. and the latter of the mind.

**ETHULIA**, in *Botany*, a name concerning whose origin or meaning we have met with no conjecture. Linnæus its author rarely explained names of his own contrivance, nor is any thing upon this occasion mentioned in his son's *Decas Prima Plantarum*, where *Ethulia* first appeared. Could he possibly allude to the remote country whence it came, as *e*, *extra*, (beyond) *Thule*, supposed by the ancients the uttermost part of the earth? If the plant had been of American origin, such an appellation would, not inelegantly, have alluded to the famous prophecy in Seneca's *Medea*, so expressive of the discovery of the western world, and ending

———"nec fit terris  
Ultima Thule."——

It was however supposed to come from Ceylon, and is actually a native of the banks of the Nile. If the above conjecture be inadmissible, the name must depend on its harmony for protection. Linnæus might well be glad to get rid of the harsh *Sparganophorus* of Vaillant, to which he would object as composed of *Sparganium*, a generic name already established. But it is probable he did not at first observe that Vaillant's genus was his *Ethulia*, though he soon recognized it. *Linn. Gen. 413. Schreb. 545. Willd. Sp. Pl. v. 3. 1740. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 158. Juss. 184. Gærtn. t. 164. (Sparganophorus; Vaill. Act. Paris. Ann. 1719. Gærtn. t. 165.)* Class and order, *Syngenesia Polygamia-equalis*. *Nat. Ord. Compositæ discoideæ*, *Linn. Corymbifera*, *Juss.*

*Gen. Ch.* *Common Calyx* rounded, simple, of many linear, equal, spreading-pointed scales. *Cor.* compound, discoid. Florets all fertile, numerous, uniform, tubular, funnel-shaped, with some space between them; their limbs five-cleft, erect. *Stam.* Filaments five, very short, capillary; anthers united into a cylindrical tube. *Pist.* Germen angular; style thread-shaped, the length of the stamens; stigmas two, recurved. *Peric.* none, except the permanent calyx. *Seeds* solitary, truncated, top-shaped, five-sided, five-furrowed; crown none, except a prominent margin. *Recept.* naked, convex, dotted with minute excavations.

*Eff. Ch.* *Receptacle* naked. *Seed-down* none. Florets tubular, five-cleft, numerous. Scales of the calyx pointed.

This is but a vague and confused genus, depending properly on the three following species only.

1. *E. conyzoides*. *Linn. Sp. Pl. 1171. L. fil. Dec. Pl. Rar. 1. t. 1.* "Flowers panicled."—Seeds of this were sent.

sent by Professor David Van Royen to Linnæus, who raised them in his stove at Upsal, and the plant proving new, was described and figured by his son, in a work of which only two fasciculi ever appeared. Linnæus supposed it a native of Ceylon, which may possibly be correct. No new information appeared concerning it, till it was mentioned in the Hortus Kewensis as sent by Thouin, and soon afterwards Vahl discovered it to be the *Kabiria* of Forskall, so that we hence learn it to be certainly a native of the muddy banks of the Nile, where it flowers early in November. The root is annual, fibrous. Stem four feet high, alternately branched, hollow, downy, leafy. Leaves alternate, on short stalks, lanceolate, pointed, equally serrated, fragrant, downy beneath, three inches long; without stipulas. Flowers pale blue, in compound corymbose panicles about the tops of the branches, remarkable for the slender and distant tubes of their florets. The seeds form an almost globose head; each of them is crowned with a pale undivided angular border.

2. *E. Sparganophora*. Linn. Sp. Pl. 1171. (Sparganophorus Vaillantii; Gærtner, v. 2. 395. t. 165.) "Flowers in sessile axillary clusters. Calyx-scales recurved."—This we know only from the work of Vaillant, (from whom Linnæus adopted it,) and that of Gærtner; nor is its native country ascertained. The leaves are said to be like those of Golden Rod. Seeds exactly like the last in general structure, nor does there seem any doubt of their belonging to one and the same genus.

3. *E. Struchium*. Swartz. Prod. 111. (Struchium; Browne Jam. 312. t. 34. f. 2.) Flowers axillary, sessile, mostly solitary. Calyx with straight spinous points.—Gathered by Browne in Jamaica. Stem herbaceous, two or three feet high, leafy, smoothish. Leaves elliptic-lanceolate, four or five inches long, pointed, strongly serrated, thin, very slightly pubescent, on stalks an inch in length. Flowers small, axillary, sessile, either solitary or in pairs, or if more together, they have smaller leaves between them. We presume the straight spinous points of the calyx-scales will afford a certain specific difference between this and the last, whether their foliage be different or not.

In his first Mantissa, p. 110, Linnæus added three species to his genus *Ethulia*. Of these *E. tomentosa* must be entirely struck out of the system, being no other than his own *Artemisia chinensis*, and not having either the habit or characters of an *Ethulia*. The second is *E. divaricata*, Burm. Ind. 176. t. 58. f. 1. (*Chrysanthemum bengalense angustifolium pusillum, summo caule ramosum*; Pluk. Phyt. t. 21. f. 4.) Leaves linear, toothed, decurrent. Flowers solitary, stalked, terminal. Stem divaricated.—Native of rice-fields in Malabar. Koenig. Root annual. Stem three or four inches high, erect, much branched in a corymbose manner; branches leafy, quadrangular, winged, somewhat cottony. Leaves alternate, linear-lanceolate, toothed, running down into the wings of the branches. Flowers on short, simple, solitary, terminal stalks; Calyx of numerous, imbricated, sharp and somewhat spinous, spreading, purplish scales. Seeds without any crown.—We have, as Willdenow has already done, presumed to correct the description of Linnæus, and his quotation of Burmann. Linnæus moreover quotes his own *Artemisia minima*, Sp. Pl. ed. 1. n. 19, with the original specimen before him, for this *Ethulia*, but very erroneously, and his citation of Burmann is so placed as to imply that he had committed the same fault, which is not true. We cannot but observe here that Burmann in his Flora Indica has copied *E. conyzoides* and *E. Sparganophora* from Linnæus, without any real knowledge of them, so that his authority is of no avail respecting

those species. Gærtner, v. 2. 389. t. 164, retains this *E. divaricata* as the only real *Ethulia*, adding a good synonym from Plukenet (who figures the plant twice), *Chrysanthemum parvum ramosissimum, membranaceo-caule maderaspatense*; Pluk. Phyt. t. 160. f. 5. Gærtner therefore preserves the name and genus of Vaillant's *Sparganophorus*, which he contends is a very distinct genus from this plant. In the last particular he appears to be right, but the above three species unquestionably constitute what Linnæus meant by *Ethulia*, and they only agree with his generic description, so that the *divaricata* ought perhaps to be referred, notwithstanding its want of a seed-crown, to the *Grangea* of Adanson and Jussieu, as the latter suspects, or rather to make a genus by itself. (See GRANGEA.) Jussieu indeed preserves Browne's *Struchium* as a genus, but, as we presume, improperly.

One more supposed *Ethulia* remains to be noticed, named *bidentis*, Mant. 110, from its resemblance to *Bidens tripartita*. This has nothing to do with the genus under consideration, being the very identical *Flaveria capitata* of Jussieu, of which we shall speak under that name hereafter. It is a native of Chili.

With the *Ethulia uniflora* of Walter and Willdenow, we are not at all acquainted. S.

ETIENNE, in Biography, the name of a family who have been celebrated as learned printers, and are more commonly known by the epithet of Stephanus, or in English by that of the learned Stephens. The founder of the family was Henry, a printer at Paris. He is chiefly distinguished as the editor of a Pfalter, in which the compositions were divided into verses, and distinguished by figures, being the first book of Scripture in which this practice was observed. He died at Lyons, leaving behind him three sons, all eminent printers, of whom the second was,

ETIENNE, ROBERT. This young man worked at first under Simon de Colines, who had married his mother, and then set up in business for himself at Paris. He had received a very liberal education, and was well acquainted with the ancient languages, and was deeply skilled in principles of sound criticism. He carried the art of typography to a very high pitch of excellence, as a number of his books well known at present will testify. His office is said to have resembled a learned seminary, in which the Latin language was the only one allowed to be spoken by all the persons employed by him. He established an early reputation by the editions of the bible in different languages. He was the first person who introduced the division of the whole into verses; of which, we are informed, he made the necessary preparations, as he was on a journey on horseback from Paris to Lyons. These divisions have been useful as marks for reference, but in other respects they have been injurious to the work, on account of the faultiness of the divisions which not unfrequently give a wrong sense to important passages of the sacred writings. In the year 1532 he published his excellent "Thesaurus Linguæ Latinæ" in two volumes folio. This work obtained a very high reputation, and has passed through many editions: the best are said to be that printed in London in 1734, and the one printed at Basil in 1740. Both editions consist of four volumes folio. In the year 1539 the reputation of Robert attracted the attention of Francis I. who reimbursed him some of his expences in procuring manuscripts and founding new types, and gave him the honour of king's printer for Greek and Latin books. At the reformation this worthy printer, in common with many biblical critics, fell under the suspicion of heresy, and endured a long persecution excited by the doctors of the Sorbonne, who, in the year 1548 unanimously decreed that

## ETIENNE.

that his bible with a version by Leo Judæ, and notes, ought to be suppressed, and placed in the list of prohibited books. By many liberal and respectable persons Etienne was supported against the fanaticism of bigots and priests, but, at length, he thought it advisable to withdraw to Geneva, where he more openly avowed himself a friend to the reformed religion. He felt himself called on to vindicate his conduct, and published an apology, in which he retaliated upon his persecutors, and the church, by whom he had been driven into a kind of exile. At Geneva he continued to follow his profession, and published many books in favour of the Protestant cause. He was elected burgher of Geneva, and lived in habits of friendship with Beza and Calvin. He died in the year 1559, at the age of fifty-six. He has been, since his death, to the present day, the theme of admiration with the learned, and by the illustrious De Thou he was considered as better entitled to the gratitude of his country, by the perfection which he gave to the art of printing, than those warriors who had extended the boundaries of the French empire. Moreri.

ETIENNE, CHARLES, a physician of the faculty of Paris, who is considered by his biographers as an honour to the age in which he lived, in consequence of the extent and variety of his attainments. He was born about the year 1503. His father, Henry Etienne, and his brothers, Francis and Robert, were all celebrated for the ingenuity with which they cultivated the art of printing. But this family was not less unfortunate than ingenious; for, being attached to the cause of the Protestant reformation, some of them were banished from France, and others died in prison. Charles, however, during these troubles, lived and flourished at Paris, where he had for many years practised his profession, when his brother Robert became the object of persecution, and fled to Geneva. He immediately undertook the superintendance of his printing-office, which he continued to manage for several years, in the hope of effecting the restoration of his brother, practising medicine at the same time with his former distinction and success. Robert died at Geneva, however, in 1559; and Charles terminated his life unfortunately, a few years afterwards, having died in a dungeon in 1564, at the age of about sixty.

Dr. Etienne, the subject of this article, made several discoveries of minor importance in anatomy, which had escaped his predecessors, especially Galen, of whom he was a great admirer; he published some anatomical figures, the execution of which, however, was claimed by a surgeon of the name of Riviere, and generally allowed to be his; but the explanations were admitted to be Etienne's. He published a great number of works, some of which have no connection with his profession, especially the histories of Lorraine, of Flanders, and of the dukes of Milan. The works relative to medicine, besides the anatomical book just mentioned, were principally on botanical subjects. He also wrote a volume, consisting of three books, "De Nutrimētis," Paris, 1550. Eloy.

ETIENNE, HENRY, the son of Robert, was born at Paris in 1528, and became distinguished as one of the most learned men of his time. His father spared neither pains nor expence in his education, and the youth had a great facility in acquiring the Greek language. At the age of eighteen he assisted his father in collating the MSS. of Dionysius Halicarnensis. After he had performed this business he set out on his travels; staid some time in Italy, where he became well acquainted with the learned men of that country, and obtained much valuable information from the Italian libraries. From Italy he came to England, and

from thence he passed through the Low Countries in his way to Paris, whither he returned at the moment his father was driven from that city. Here he followed the united professions of printer and editor. In 1554 he published the Odes of Anacreon from the MSS. which he found in Italy. He accompanied his edition with fragments of Sappho and other lyric poets, and with an elegant metrical version. To him the learned are likewise indebted for various other Greek authors, published from MSS. which he had collected in his travels, all of which he corrected and enriched with valuable annotations. In 1572 he published his "Thesaurus Linguæ Græcæ," in four volumes folio, a capital companion to the Latin Thesaurus by his father. Scapula made an abridgement of this vast work, which greatly hindered the sale of the original, and thus defrauded the learned author of the recompence to which he had the most solid claim. This valuable man was protected by Henry IV. of France, who was so far attached to him, that he employed him in a work entitled "Sur la precellence de la Langue Francoise." He was, however, too deeply imbued with the liberal principles which real literature almost always infuses in the minds of her votaries, to escape the malice of the monks. They brought a prosecution against him for his "Preparation à l'Apologie pour Herodote." Apprised of his great danger, and well knowing the rancour of his enemies, he fled from the city and took refuge in the mountains of Auvergne. Scarcely had he left the city, when finding that he had escaped their cruel fangs, they burnt the excellent man in effigy, regretting, no doubt, that they had not his person on which to wreak their vengeance. After this Etienne resided chiefly at Geneva, though he made occasional visits to his literary friends in Germany and France. He was subject to many difficulties, and doomed to other and severe persecutions, which at length so far broke his spirits as to cause derangement, and in this state, as well as in poverty, he died at an alms-house at Lyons in 1598. Besides editing the *Poetæ Græci Principes*; *Maximus Tyrius*; *Diodorus Siculus*; *Medicæ artis Principes post Hippoc.* and *Galen*; and the *Nov. Test. Græc.*, to which he prefixed an admirable preface; he was author of some excellent pieces, besides what have been already mentioned; *viz.* *Dialogues "De bene instituendis linguæ Græcæ studiis;" "De criticis veteribus Græcis et Latinis,"* and other pieces in the French language, as well in verse as in prose. He was a man of many singularities, but truly respectable, and highly respected. He left several children, of whom his son Paul succeeded him in his Genevan printing-office, and inherited a share of his reputation. Moreri.

ETIENNE, *Saint*, in Latin *Fanum Sancti Stephani*, or *Furania*, in *Geography*, a considerable town of France, in the department of the Loire, chief place of a district of the same name, with a population of 16,259 individuals. It is situated on the river Furan, 36 miles S.W. of Lyons, and 348 miles S. by E. of Paris. N. lat. 45° 22'. The town is divided into two cantons, East and West, the former with three communes and 12,735 inhabitants, the latter with three communes and 14,669 inhabitants; the whole canton has a territorial extent of 92½ kilometres. There are at Saint Etienne and in the neighbourhood several manufactures of swords and fire arms, cutlery, and hardware of all sorts, ribbands, silks, and good bleaching grounds. The district abounds with coal-mines, and the proximity of two large rivers, the Rhône and Loire, affords great facility for the transport of the produce of the manufactures.

As chief place of a district, Saint Etienne has a sub-prefect, two courts of justice, and a register office. The district contains 9 cantons, 76 communes, and 99,261 inhabitants,

ants, on a territorial extent of  $1142\frac{1}{2}$  kilometres.—Also, a small town of France, in the department of the Maritime Alps, chief place of a canton in the district of Puget-Théniers, with a population of 1689 individuals; its canton has a territorial extent of  $212\frac{1}{2}$  kilometres, and three communes, with 3089 inhabitants.

ETIENNE *de Baigorry, Saint*, a town of France, in the department of the Lower Pyrenées, chief place of a canton in the district of Mauléon, with a population of 6187 individuals. The canton contains 10 communes and 10,939 inhabitants, on a territorial extent of 210 kilometres.

ETIENNE *de Cuines, Saint*, a small town of France, in the department of Montblanc, chief place of a canton in the district of St. Jean de Maurienne, with a population of 830 individuals. The canton has a territorial extent of  $117\frac{1}{2}$  kilometres and 6 communes, with 6496 inhabitants.

ETIENNE *de Lugdarès, Saint*, a small town of France, in the department of the Ardèche, chief place of a canton in the district of l'Argentiere, with a population of 1509 individuals. The canton has seven communes and 3439 inhabitants, on a territorial extent of 185 kilometres.

ETIENNE *de Montluc, Saint*, a town of France, in the department of the Lower Loire, chief place of a canton in the district of Savenay, with a population of 4118 individuals. The number of the inhabitants of the canton amounts to 12,453; they are dispersed in five communes, on a territorial extent of  $272\frac{1}{2}$  kilometres.

ETIENNE *de Saint Geoire, Saint*, a small town of France, in the department of the Isère, chief place of a canton in the district of St. Marcellin. It has 1546 inhabitants, and its canton comprises, on a territorial extent of  $162\frac{1}{2}$  kilometres, 13 communes, with a population of 9381 individuals.

ETIENNE *en Dévoluy, Saint*, a small town of France, in the department of the Upper Alps, chief place of a canton in the district of Cap, with only 766 inhabitants: but the canton has four communes, and a population of 2184 individuals, on a territorial extent of  $262\frac{1}{2}$  kilometres.

ETIENNE *les Orgues, Saint*, a small town of France, in the department of the Lower Alps, chief place of a canton in the district of Forcalquier, with a population of 984 individuals. The canton has a territorial extent of  $272\frac{1}{2}$  kilometres, 12 communes, and 4260 inhabitants.

ETIOLATION *of Plants, in Gardening*, the rendering them white, crisp, and tender, by excluding the action of light from them. See BLANCHING.

ETIQUETTE, a French term, primarily denoting a ticket or title affixed to a bag or bundle of papers, expressing its contents. It is also used when applied to the Spanish and some other courts, to signify a particular account of what is to be done daily in the king's household, and in the chief ceremonies relating to it. It likewise denotes those forms that regulate the decorum of conduct towards persons of various ranks and stations.

ETIVAZ *in Geography*, a small town of Switzerland, in that part of the canton of Berne which is called the Ober Land, or Upper Country, being at the foot of the highest Alps, and extending to the glaciers, or ice mountains. It is situated in the district of Gessenay, and is remarkable for its mineral springs, the water of which has a sulphureous taste.

ETLINGEN, or ETTLINGEN, a small town of Germany, in the grand duchy of Baden, situated on the river Alb, between Pfortzheim and Raftadt, at the distance of 12 miles from each. N. lat.  $48^{\circ} 55'$ .

ETMARSHAUSEN, or ETMERSHAUSEN, a small town of Germany, in the duchy of Saxe Coburg, in the district of Saltzungen, remarkable only for the following inscription, which is engraved on an old garden gate of stone,

in Latin characters: "wer weiß obs wahr ist," (who knows whether it be true.) It is become a proverbial saying in that part of Saxony, and frequently used as a polite insinuation that a person is suspected of having rather deviated from or embellished the truth; people then observe that what has been related is engraven at the garden gate at Etmarshausen. The origin, occasion, or motive of the inscription itself, has never yet been explained, and has puzzled several antiquaries of the neighbourhood.

ETMASER, a town of Arabia, in the province of Yemen; 36 miles N. of Chamir.

ETMULLER, MICHAEL, *in Biography*, an eminent physician, was born at Leipzig on the 26th of May, 1644. Possessing a taste for the sciences which his native city afforded him the most ample means of cultivating, he diligently studied under the celebrated professors of that period. He afterwards spent a considerable time in travelling through France, England, Holland, Italy, and Germany, with a view to the farther acquisition of knowledge; and on his return took the degree of doctor of medicine at Leipzig in August 1668. In the year 1676, he was appointed professor of botany in that university, and extraordinary professor of surgery and anatomy. He fulfilled those offices with great applause; and his death, which happened on the 9th of March, 1683, when he was but 39 years of age, was generally regretted by the faculty of Leipzig. The disorder, which occasioned it, was contracted while he was employed in some chemical experiments. He was a very voluminous writer, and his works were deemed sufficiently interesting at the time of their publication to be translated into most of the European languages. His medical practice and opinions were built upon the theory of Sylvius de la Boë, and the chemical sect.

ETMULLER, MICHAEL ERNEST, son of the preceding, was born at Leipzig on the 26th of August, 1673; and, after having studied at Zittau, Altemberg, and other schools of Germany, he took the degree of doctor of medicine at his native place, in 1697. He afterwards travelled to the most eminent universities of Europe, and became successively professor of anatomy, of philosophy, and of pathology at Leipzig. He had likewise been two years director of the Academia Naturæ Curiosorum, when his death occurred, on the 25th of September, 1732. He has left some dissertations of his own, but is chiefly known as the editor of the works of his father.

ETNA. See ÆTNA.

ETOBESA, or ETOBEMA, *in Ancient Geography*, a town of Spain, in Edetania, mentioned by Livy under the name of Etovissa, and situated at some distance W. of Valencia.

ETOCETUM, a place in the isle of Albion, according to the Itinerary of Antonine, which Gale fixes at Wall, near Litchfield.

ETOILE, *in Geography*, a town of France, in the department of Drôme, and district of Valence; 3 leagues N.W. of Crest.

ETOLIA. See ÆTOLIA.

ETON, *in Geography*, a large village in the hundred of Stoke, and county of Buckingham, England, is noted for its great public seminary, or college, in which many eminent statesmen, authors, military heroes, &c. have received their scholastic education. This college was originally founded by king Henry the Sixth, in the year 1440, for a provost, ten priests, four clerks, six choristers, twenty-five poor grammar-scholars, and twenty-five poor men. The first provost was Henry Sever, who was succeeded by William Waynfleet, founder of Magdalen college, Oxford. This foundation
